
Oil of Cajuput

Oil of cajuput is obtained by distillation and rectification from the fresh leaves and twigs of *Melaleuca Leucadendron* Linn. and other species of *Melaleuca*, trees indigenous to Northern Australia, the Malay Archipelago, etc., the oil being distilled in the Molucca Islands, rectified by steam distillation, and imported by way of Batavia and Singapore. The green colour of the oil when first distilled is due to contamination with copper; it is removed by the subsequent steam distillation. Oil of cajuput occurs as a colourless or yellow liquid, with an agreeable, camphoraceous odour, and a bitter, aromatic, camphoraceous taste. It **contains** from 50 to 65 per cent. of cineole, $C_{10}H_{18}O$, and also terpineol and its acetic ester, together with *l*-pinene, and valeric, butyric, benzoic and other aldehydes. It should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) in all proportions.

Standard, B.P.—Oil of cajuput contains not less than 50 per cent. and not more than 60 per cent. w/w of cineole, $C_{10}H_{18}O$. Specific gravity, 0.916 to 0.926. Optical rotation, not greater than -4° . Refractive index at 20° , 1.462 to 1.472. Soluble in 2 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640), becoming less soluble with age.

Action and Uses.—Oil of cajuput has the typical action of a volatile oil and is antispasmodic and carminative. It is an intestinal antiseptic and has been given internally in chronic rheumatism due to intestinal toxæmia. It is excreted by the bronchi and is employed as an antiseptic in the treatment of phthisis. Externally, it acts as a stimulant and mild counter-irritant. It is applied to inflamed and rheumatic joints, diluted with 2 parts of olive oil or turpentine liniment. The oil is **administered** on sugar, in capsules, or as Spiritus Cajuputi, sometimes in combination with spirit of chloroform and aromatic spirit of ammonia.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

Preparation

Spiritus Cajuputi, B.P.—(Sp. Cajuput.)—Spirit of Cajuput. Oil of cajuput, 10 per cent. v/v, in alcohol (90 per cent.). Dose.—0.3 to 2 millilitres (5 to 30 minims).

OLEUM CAMPHORÆ RECTIFICATUM

(Ol. Camph. Rect.)

Rectified Oil of Camphor

Synonyms.—White Oil of Camphor; Light Oil of Camphor; Oleum Camphoræ Essentiale; Essential Oil of Camphor.

Rectified oil of camphor consists of the lighter fractions of the oil obtained as a by-product in the manufacture of camphor from the camphor laurel, *Cinnamomum Camphora* T. Nees and Eberm. It occurs as a colourless or yellowish liquid, having the odour of camphor. Its properties and composition are very variable, largely on account of the more or less complete separation of the camphor and safrole. The chief constituents of the oil are terpenes. The natural oil **contains** safrole, acetaldehyde, camphor, terpineol, eugenol, cineole, *d*-pinene, phellandrene, dipentene and cadinene. The heavy fractions of the oil are valuable as a source of safrole which is used in the preparation of synthetic heliotropin. These have a specific gravity of 1.015 to 1.025 and are known commercially as "brown camphor oil."

Soluble in alcohol (1 in 3).

Standard.—Rectified oil of camphor contains not less than 35 per cent. of cineole. Specific gravity, 0.875 to 0.900. Optical rotation, +9° to +24°. Refractive index at 20°, 1.465 to 1.470.

Assay.—Determine the freezing-point of a mixture of 1.5 grammes of the oil, 1.5 grammes of eucalyptol and 2.1 grammes of *o*-cresol, by the method of the British Pharmacopœia for the determination of cineole; the freezing-point is not below 40° (equivalent to 35 per cent. of cineole).

Action and Uses.—Rectified oil of camphor is employed as a rubefacient and mild counter-irritant to rheumatic and inflamed joints. It may be applied undiluted, or mixed with an equal quantity of olive oil, or with methyl salicylate. It is also used as a parasiticide.

Preparations

Linimentum Methylis Salicylatis, B.P.C.—(Lin. Methyl. Salicyl.)—Liniment of Methyl Salicylate. *Syn.*—Linimentum Betulæ Compositum; Compound Liniment of Birch. Rectified oil of camphor, 1 in 4, with menthol, oil of eucalyptus and methyl salicylate.

Linimentum Methylis Salicylatis Compositum, B.P.C.—(Lin. Methyl. Salicyl. Co.)—Compound Liniment of Methyl Salicylate. Rectified oil of camphor, 1 in 4, with menthol, chloral hydrate, methyl salicylate and chlorophyll.

OLEUM CARDAMOMI

(Ol. Cardamom.)

Oil of Cardamom

Oil of cardamom is obtained by distillation from the whole fruits of *Elettaria Cardamomum* Maton var. *minuscule* Burkill, cultivated in

Ceylon, Mysore, Travancore and Cochin. Oils derived from other species have been examined, but they are inferior in quality, less soluble, and contain a smaller quantity of ester. Oil of cardamom occurs as a colourless or pale yellow oil, with a pungent, aromatic odour and a pleasant, cooling taste. It **contains** cineole, limonene, and terpineol combined as formic and acetic esters.

Standard.—Oil of cardamom has a specific gravity of 0.923 to 0.945. Optical rotation, $+20^{\circ}$ to $+44^{\circ}$. Refractive index at 20° , 1.461 to 1.467. Ester value, 90 to 156. It is soluble in 4 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Action and Uses.—Oil of cardamom has carminative properties, and is sometimes used as a flavouring agent.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

OLEUM CARI

(Ol. Cari)

Oil of Caraway

Synonym—Oleum Carui.

Oil of caraway is obtained by distillation from freshly crushed caraway, and subsequent rectification. It occurs as a colourless or pale yellow liquid, with a characteristic odour and a mild, spicy taste. Exposure to the air causes the oil to become viscous and to increase in specific gravity. This also applies to carvone, the chief constituent of the oil. Oil of caraway **contains** about 58 per cent. of carvone. The only other important constituent is the terpene, *d*-limonene, also called carvene, the specific gravity of which is 0.846, the optical rotation, about $+107^{\circ}$, and the boiling-point, 175° to 176° . Carvacrol is said to be present in traces. Oil of caraway should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of caraway contains not less than 53 per cent. and not more than 63 per cent. w/w of carvone, $C_{10}H_{14}O$. Specific gravity, 0.910 to 0.920. Optical rotation, $+70^{\circ}$ to $+80^{\circ}$. Refractive index at 20° , 1.485 to 1.492. It is soluble in an equal volume of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340), and in 7 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640).

Action and Uses.—Oil of caraway is an aromatic carminative and is used in purgative pills to allay the tendency to gripe. It may be administered on sugar to relieve flatulent colic, and as Aqua Cari to children for the same purpose.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

CARVONUM.—Carvone, $C_{10}H_{14}O$, is a ketone contained in caraway, dill and spearmint oils. That occurring in caraway and dill oils is dextrorotatory, while that from spearmint oil is levorotatory. It occurs as a thickish, colourless or slightly yellow liquid with an odour of caraway. Specific gravity, about 0.965. Boiling-point, about 224° . It is miscible with all proportions of alcohol, soluble in alcohol (70 per cent.) (1 in 2), and in alcohol (50 per cent.) (1 in 20); carvone containing 2 per cent. of limonene will not form a clear solution under these conditions. Carvone has the aromatic and carminative properties of oil of caraway.

OLEUM CARYOPHYLLI

(Ol. Caryoph.)

Oil of Clove

Oil of clove is obtained by distillation from clove and is largely imported from Zanzibar and Pemba. It occurs, when freshly distilled, as a colourless or pale yellow liquid, which darkens with age or on exposure to the air, becoming reddish-brown. It has a strongly aromatic odour and a persistent burning taste. Oil of clove **contains** about 88 per cent. of eugenol, $C_{10}H_{12}O_2$, which is the most valuable and characteristic constituent of the oil. It may be extracted by treating the oil with dilute sodium hydroxide solution, washing the solution with ether and decomposing it with sulphuric acid. Oils containing 95 per cent. or more of eugenol are less fragrant and are used chiefly for the manufacture of vanillin. Oil of clove also contains the sesquiterpene, caryophyllene, $C_{15}H_{24}$, furfural, $C_5H_4O_2$, which is probably the cause of the oil darkening on storage, methylamylketone, $C_5H_{11}COCH_3$, a body which communicates the much valued fruity odour to the oil, vanillin, methyl salicylate and about 10 per cent. of acetylene. It should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) in all proportions; soluble in ether and glacial acetic acid.

Standard, B.P.—Oil of clove contains not less than 85 per cent. and not more than 90 per cent. v/v of eugenol, $C_{10}H_{12}O_2$. Specific gravity, 1.047 to 1.060. Refractive index at 20° , 1.528 to 1.537. It is soluble in 2 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Action and Uses.—Oil of clove, like other volatile oils, is antiseptic and antiputrescent, and is often employed as a preservative. Internally, oil of clove is antispasmodic and carminative; doses of 3 to 5 minims have been given in phthisis, to reduce expectoration in coughs. Applied externally, it is rubefacient, counter-irritant and slightly anæsthetic; mixed with two parts of olive oil it may be applied to neuralgic areas; as *Linimentum Succini Compositum*, it is employed as an embrocation for bronchitis, whooping cough and rheumatism. Oil of clove may be **administered** on sugar or in capsules to allay flatulent colic, and is added to purgative pills to prevent gripe. Pills containing a large

proportion of oil may be massed by the addition of a little soap. Oil of clove is applied on cotton wool to allay pain in dental caries, and as a dressing and an ingredient of temporary fillings in dental practice. It is used in microscopy as a clearing agent.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

· OLEUM CASSIÆ

(Ol. Cass.)

Oil of Cassia

Oil of cassia is obtained by distillation from the leaves and twigs of *Cinnamomum Cassia* Blume, cultivated in Southern China, and rectified by redistillation. It occurs as a mobile, yellowish, strongly refractive liquid, having an odour and taste resembling those of oil of cinnamon, but the odour is less fragrant and more pungent, and the taste, which is sweetish, spicy and burning, is harsher than that of oil of cinnamon. It is optically inactive, or only slightly dextrorotatory or slightly lævorotatory. The alcoholic solution is slightly acid to litmus. Boiling-point, 240° to 260°, with partial decomposition. On exposure to air, the oil becomes darker in colour and more viscous. On cooling the oil to 0° and then shaking it with an equal volume of nitric acid, a crystalline mass is formed. Oil of cassia **contains** cinnamic aldehyde; it also contains cinnamic acid, cinnamyl acetate, and a terpene. It should be **stored** in well-stoppered, amber-coloured bottles.

Standard.—Oil of cassia, determined by the method of the British Pharmacopœia for the determination of cinnamic aldehyde in *Oleum Cinnamomi*, contains not less than 80 per cent. w/w of aldehydes, calculated as C_9H_8O . Specific gravity, 1.055 to 1.065. Refractive index at 20°, 1.600 to 1.606. It complies with the limit test for lead in *Oleum Anisi*. It is soluble in 2 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640); it yields a clear solution with 3 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901) and no turbidity is produced in the solution on the addition of lead acetate solution (absence of resins). 0.2 millilitre dissolved in 10 millilitres of alcohol produces on the addition of a drop of ferric chloride solution a brown, but not a green or blue, colouration (limit of oil of clove and phenols).

Action and Uses.—Oil of cassia has properties resembling those of oil of cinnamon. As a flavouring agent it is inferior to oil of cinnamon.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{4}$ to 3 minims).

OLEUM CEDRI

(Ol. Cedri)

Cedar Wood Oil*Synonym*—Oil of Red Cedar.

Cedar wood oil is obtained by distillation from the wood of various species of red cedar, the chief of which is *Juniperus virginiana* Linn., a North American tree, in which the oil exists to the extent of 2·5 to 4·5 per cent. It occurs as an almost colourless or slightly yellow, somewhat viscous liquid, occasionally containing crystals of cedar camphor, and having a mild but persistent, characteristic odour. An inferior oil is obtained in America as a by-product in the process of drying wood for the manufacture of lead pencils; it contains only the more volatile portions of the natural oil and has a lower specific gravity. Cedar wood oil **consists** almost entirely of cedrene, a liquid sesquiterpene, $C_{15}H_{24}$, which can be separated by fractional distillation; boiling-point 261° to 262° ; specific gravity, about 0·9351. It may also contain a solid substance, cedar camphor or cedrol, $C_{15}H_{26}O$, a sesquiterpene alcohol melting at 86° to 87° after purification. The oil used for microscopical purposes, having a refractive index of 1·515 to 1·526, is specially prepared and is a mixture of cedar wood oil with other substances.

Soluble in alcohol (1 in 20 to 1 in 10).

Standard.—Cedar wood oil has a specific gravity of 0·941 to 0·950. Optical rotation, -25° to -46° ; Refractive index at 20° , 1·495 to 1·510.

Action and Uses.—Cedar wood oil has been recommended for use in place of oil of sandal wood in the treatment of gonorrhœa, but is rarely so employed. It is used for its odour in perfumery and as a clearing agent in microscopy.

OLEUM CHAULMOOGRE

(Ol. Chaulmoog.)

Chaulmoogra Oil

Chaulmoogra oil is obtained by expression from the seeds of *Hydnocarpus Kurzii* (King) Warb. It occurs as a solid fat, or, at tropical temperatures, as a brownish-yellow oil, with a characteristic odour, a somewhat acrid taste and an acid reaction. A mixture of 1 millilitre of the oil with 0·05 millilitre of sulphuric acid acquires a reddish-brown colour, changing to olive-green. The oil **consists** mainly of glycerides of chaulmoogric acid, $C_{18}H_{32}O_2$, and hydnocarpic acid, $C_{16}H_{28}O_2$, with smaller quantities of glycerides of palmitic acid, and fatty acids the exact nature of which has not been ascertained.

Soluble in ether, chloroform and carbon disulphide.

Standard.—Chaulmoogra oil has a melting-point of about 25°. Specific gravity, about 0.95 at 25°. Specific rotation at 20°, determined on a 10 per cent. w/v solution in chloroform, +48° to +52°. Acid value, 22 to 30. Saponification value, 196 to 213. Iodine value, 98 to 104. Melting-point of the mixed fatty acids, 44° to 45°.

Action and Uses.—Chaulmoogra oil probably owes its beneficial properties to the presence of the characteristic, cyclic, unsaturated chaulmoogric and hydnocarpic acids. It is used almost exclusively in the treatment of leprosy, and its employment has given good results. It acts possibly by stimulating the leucocytes and by penetrating the wall of the leprosy bacillus, thus rendering it more vulnerable. It may be used externally by inunction, alone or diluted with oil it may be injected, and orally it may be **administered** in capsules or as an emulsion. Injections of the oil may at first be given weekly, the dose being gradually increased and the interval between the injections diminished. Chaulmoogra oil for **injection** may be sterilised by heating at 150° for one hour.

Dose.—0.3 to 1 millilitre (5 to 15 minims), increased gradually to 4 millilitres (60 minims), by the mouth; 2 millilitres (30 minims), increased gradually to 5 millilitres (75 minims), by subcutaneous and intramuscular injection.

Preparation

Unguentum Chaulmoogræ, B.P.C.—(Ung. Chaulmoog.)—Chaulmoogra Ointment. Chaulmoogra oil, 10 per cent., in hard and soft paraffins.

This ointment was included in the British Pharmacopœia, 1914

OLEUM CHENOPODII

(Ol. Chenopod.)

Oil of Chenopodium

Synonym—Oil of American Wormseed.

Oil of chenopodium is obtained by steam distillation from the fresh flowering and fruiting plants, excluding roots, of chenopodium. It occurs as a colourless or pale yellow liquid, with a disagreeable, penetrating, camphoraceous odour and a bitter, burning taste. The oil is decomposed on heating; when a small quantity of the oil is heated to incipient ebullition with a fragment of unglazed porcelain and then removed from the source of heat, it continues to boil for a few seconds leaving, on cooling, a deep golden-yellow liquid. This test should be carried out cautiously as the decomposition may take place with explosive violence. Oil of chenopodium **contains** about 70 per cent. of ascaridole. It also contains *p*-cymene, α -terpinene, *l*-limonene, and *l*- Δ -2 : 8-*p*-menthadiene. It should be **stored** in a cool place and protected from light.

Standard, B.P.—Oil of chenopodium contains not less than 65 per cent. w/w of ascaridole, $C_{10}H_{16}O_2$. Specific gravity, 0.960 to 0.980. Optical rotation, -4° to -8° . Refractive index at 20° , 1.474 to 1.479. It is soluble in from 3 to 10 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Action and Uses.—Oil of chenopodium is employed as an anthelmintic for hook-worms and round-worms. The treatment for round-worms frequently consists in allowing the patient a light supper at night, administering 0.6 millilitre (10 minims) of the oil in a gelatin capsule on a fasting stomach the next morning, with another dose of the oil two hours afterwards, followed in two hours by a purge of magnesium sulphate. Food should not be taken until the purge has acted. The treatment should be repeated ten days later. Toxic symptoms are transient dizziness and vomiting. For hook-worms, the dose must be larger, and 15 minims of oil in capsules or on sugar, repeated after an interval of two hours and followed by castor oil or magnesium sulphate, may be given. A mixture of 1 volume of oil of chenopodium with 2 volumes of carbon tetrachloride is more effective, and may be given in doses of 0.1 millilitre ($1\frac{1}{2}$ minims) for each year of age up to a maximum of 1.5 millilitres (25 minims); this should be divided into 2 doses, given one hour apart and the second dose followed by magnesium sulphate. The treatment requires weekly repetition until the faeces are free from ova. Treatment for hook-worms with oil of chenopodium should not be given to patients suffering from acute diseases, cardiac or renal disease, pulmonary tuberculosis or anasarca. In cases of **poisoning**, a purgative should be administered followed by an enema; alcohol should be withheld and warmth applied to the body.

Dose.—0.2 to 1 millilitre (3 to 15 minims).

OLEUM CINNAMOMI

(Cl. Cinnam.)

Oil of Cinnamon

Oil of cinnamon is obtained by distillation from cinnamon bark. It occurs, when freshly distilled, as a light yellow liquid which darkens with age, becoming reddish-brown; it has a characteristic fragrant odour and a warm, sweet, spicy taste. It has a much more delicate odour and flavour than oil of cassia, which it resembles in composition. Adulteration with cinnamon leaf oil diminishes the cinnamic aldehyde content and increases that of the eugenol; it may be detected by the blue colour produced by adding ferric chloride to a dilute alcoholic solution. Adulteration with cassia oil increases the specific gravity and also the cinnamic aldehyde content. Oil of cinnamon **contains** chiefly cinnamic aldehyde, about 58 per cent.; the oil also contains

about 4 to 8 per cent. of eugenol, together with phellandrene and other terpenes. The value of cinnamon oil is not altogether dependent on the amount of cinnamic aldehyde it contains, as is the case with oil of cassia, but rather on the non-aldehydic bodies to which the fine flavour is probably due. It should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of cinnamon contains not less than 50 per cent. and not more than 65 per cent. w/w of cinnamic aldehyde, C_9H_8O . Specific gravity, 1.000 to 1.030. Optical rotation, 0° to -2° . Refractive index at 20° , 1.565 to 1.582. It is soluble in 3 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901), the solution being not more than slightly opalescent. It complies also with a test for absence of cinnamon leaf oil and cassia oil.

Action and Uses.—Oil of cinnamon, like the other essential oils, is carminative and possesses antiseptic properties. It is **administered** in capsules, on sugar, or as Spiritus Cinnamomi for common colds and influenza. The oil is inhaled for phthisis (30 minims in 1 pint of hot water) and is used as a spray (1 in 20 of light liquid paraffin) in catarrh. Lozenges and pastilles are also prepared containing the oil. It is used largely as a flavouring agent and sometimes as a preservative.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

ALCOHOL CINNAMICUM.—Cinnamic alcohol, $C_9H_8 \cdot CH : CH \cdot CH_2OH$, or styrone, occurs as the cinnamic or acetic ester in storax, balsam of Peru and in oils of hyacinth and other flowers. It is obtained synthetically or by hydrolysis of the naturally occurring esters, and occurs when pure as a crystalline solid, melting at 30° to 33° . Owing to the presence of traces of impurities, it usually occurs as a colourless liquid having a specific gravity of about 1.020 and a boiling-point of 258° . It has a weak but delicate hyacinth-like odour and is used in perfumery.

ALDEHYDUM CINNAMICUM.—Cinnamic aldehyde, $C_9H_8 \cdot CH : CH \cdot CHO$, occurs naturally in oils of cinnamon and cassia, and may be extracted therefrom or prepared synthetically. It occurs as a liquid having a specific gravity of 1.054 to 1.057 and a boiling-point of 253° . It is employed as an ingredient of soap perfumes.

ALDEHYDUM HYDROCINNAMICUM.—Hydrocinnamic aldehyde, $C_9H_9 \cdot CH_2 \cdot CH_2 \cdot CHO$, is prepared from cinnamic aldehyde and occurs as a colourless liquid having a specific gravity of 1.018. It has a powerful odour, is unaffected by alkalis, and is therefore used in soap perfumery.

Preparations

Capsulæ Quininae Ammoniatæ et Cinnamomi, B.P.C.—(Caps. Quinin. Ammon. et Cinnam.)—Capsules of Ammoniated Quinine and Cinnamon. Each capsule contains quinine sulphate, ammonium bicarbonate and oil of cinnamon, and is approximately equivalent to 1 fluid drachm of solution of ammoniated quinine with $\frac{1}{4}$ minim of oil of cinnamon. Dose.—1 capsule.

Capsulæ Quininae et Cinnamomi, B.P.C.—(Caps. Quinin. et Cinnam.)—Capsules of Quinine and Cinnamon. Each capsule contains 1 grain of quinine sulphate and 1 minim of oil of cinnamon. Dose.—1 capsule.

Spiritus Cinnamomi, B.P.C.—(Sp. Cinnam.)—Spirit of Cinnamon. Oil of cinnamon, 1 in 10, in alcohol (90 per cent.). Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopæia, 1914.

OLEUM CITRONELLÆ

(Ol. Citronell.)

Oil of Citronella

Oil of citronella is obtained by distillation from *Cymbopogon Nardus* Rendle, which is grown principally in Ceylon, Burma and the Straits Settlements. It occurs as a nearly colourless or pale yellow oil, with a pleasant odour. The addition of Russian petroleum or resin spirit reduces the solubility and decreases the percentage of acetylisable constituents. There are two types of oil of citronella in commerce, Ceylon and Java, the latter comprising the oils from Burma and the Straits Settlements. They differ in odour and **composition**, the chief constituents being geraniol and citronellal, the Java oil containing 30 to 40 per cent. of the latter. Ceylon oil usually contains not more than 10 per cent. of citronellal. Camphene, dipentene, limonene, traces of linalol, borneol, methylheptenone, methyleugenol and sesquiterpenes are also present.

Soluble in alcohol (90 per cent.).

Standard.—Oil of citronella (Ceylon) contains not less than 57 per cent., and oil of citronella (Java) contains not less than 85 per cent. w/w of total acetylisable constituents, calculated as geraniol. Specific gravity, (Ceylon oil) 0.897 to 0.912, (Java oil) 0.885 to 0.900. Optical rotation, (Ceylon oil) -6° to -14° , (Java oil) -2° to -5° . Refractive index at 20° , (Ceylon oil) 1.479 to 1.485, (Java oil) 1.468 to 1.473. One part of oil of citronella, when well shaken with 10 parts of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640), yields a clear or slightly opalescent solution, no globules on the surface being visible to the naked eye after the solution has stood for twenty-four hours at a temperature not lower than 15.55° (60°F.).

Assay.—Proceed by the method of the British Pharmacopœia for the determination of free alcohols in volatile oils, calculating the percentage of total acetylisable constituents as geraniol, using the formula:—

Percentage of total acetylisable constituents

$$= \frac{7.707n}{\text{Weight of acetylated oil} - 0.021n}$$

where n = the number of millilitres of $\text{N}/2$ alcoholic potassium hydroxide absorbed during the saponification of the acetylated oil.

Uses.—Oil of citronella is used as a perfume for soaps and brilliantines. It is also used as a constituent of mosquito repellants.

CITRONELLALUM.—Citronellal, as found in commerce, consists of a mixture of two isomeric aldehydes of the formula $\text{C}_{10}\text{H}_{18}\text{O}$. It is extracted from oil of citronella by means of its bisulphite compound, and occurs as a pale yellow or colourless oil, having a specific gravity of about 0.855 to 0.860 and a boiling-point of 205° to 208° . It is used in perfumery and in the manufacture of hydroxycitronellal.

CITRONELLOLUM.—Citronellol, as found in commerce, consists of a mixture of two isomeric alcohols of the formula $\text{C}_{10}\text{H}_{20}\text{O}$. It may be obtained by the reduction

of citronellal and occurs as a colourless liquid with a faint rose odour, and has a specific gravity of about 0.860 and a boiling-point of about 225°. It is used in perfumery.

HYDROXYCITRONELLALUM.—Hydroxycitronellal, or lily aldehyde, is prepared from citronellal and consists of a mixture of at least two substances, namely hydroxycitronellal and dihydroxycitronellal. It occurs as a colourless or pale yellow oil with a powerful, sweet odour, having a specific gravity of about 0.955 and a boiling-point of about 115° to 135° under 10 mm. pressure. It is used in perfumery.

OLEUM COCOIS

(Ol. Coccois)

Coconut Oil

Coconut oil is a fat obtained by expression from the kernels of the coconut, the fruit of *Cocos nucifera* Linn. and *C. butyraceæ* Linn. It occurs as a solid, white or pearl-white fat, of the consistence of lard, having a bland taste and an odour of coconut. On exposure to the air, the oil readily turns rancid, acquiring an unpleasant odour and a strong acrid taste. It is readily saponified by the strong alkalis and, since the soap formed is not easily precipitated by salt solution, it is largely used in making "marine" soap. The solid fats are often separated from the liquid by cold pressure and deodorised for various technical uses. The "stearin" so obtained is sometimes used as an adulterant of oil of theobroma. Coconut oil melts between 20° and 26°. The chief glycerides of the oil are trimyristin and trilaurin; it contains smaller proportions of tripalmitin, tristearin and triolein, and the glycerides of the volatile caproic, caprylic and capric acids.

Soluble in alcohol (1 in 2) at 60°, less soluble at ordinary temperatures; very soluble in ether, chloroform and carbon disulphide.

Standard.—Coconut oil has a solidifying-point of 22° to 23.5°. Refractive index at 40°, 1.4485 to 1.4495. Acid value, not more than 6. Saponification value, 255 to 258. Iodine value, 7.9 to 9.5.

Action and Uses.—Coconut oil has been recommended as an ointment basis on account of its ready absorption; Unguentum Olei Coccois is suitable for this purpose. Coconut oil is used as a lubricant in massage, as a dressing for the hair, and in the manufacture of soap and margarine. Liquor Saponis Olei Coccois is used as a shampoo in dermatological practice.

PALM-KERNEL OIL, sometimes called palm-nut oil, a fat much resembling coconut oil, is obtained by pressing the kernels of the fruit of the palm tree, *Elais guineensis* Jacq., growing on the West Coast of Africa. It occurs as a white fat which, when free from rancidity, possesses a pleasant odour and nutty taste. In composition and general characters it closely resembles coconut oil, and when deodorised can be distinguished from the latter only with some difficulty, especially in mixtures; melting-point, 21° to 24°; solidifying-point, 26° to 26.5°; saponification number, 246 to 249; iodine value, 14 to 19. It should be carefully distinguished from palm oil (see Oleum Palmæ). Palm-kernel oil is used for the same purposes as coconut oil.

Preparations

Liquor Saponis Olei Coccois, B.P.C.—(Liq. Sap. Ol. Coccois)—Solution of Coconut Oil Soap. An aqueous solution of the sodium and potassium soaps of the fatty acids of coconut oil, saturated with thymol.

Unguentum Olei Coccois, B.P.C.—(Ung. Ol. Coccois)—Coconut Oil Ointment. Coconut oil, 7 parts, and white soft paraffin, 3 parts.

OLEUM COPAIBÆ

(Ol. Copaib.)

Oil of Copaiba

Oil of copaiba is obtained by distillation from the oleo-resin of various species of *Copaifera* Linn., indigenous to Brazil, Venezuela, New Granada, and other parts of Central and South America. It occurs as a colourless or pale yellow liquid, having the characteristic pepper-like odour of the balsam, a bitter, pungent, persistent taste, and a neutral reaction. The chief adulterants are gurjun oil and oil of African copaiba. Pará copaiba yields 60 to 90 per cent of oil and Maracaibo and Maranhão copaiba about 45 per cent. The chief and only well-defined constituent of oil of copaiba is the sesquiterpene, caryophyllene, $C_{15}H_{24}$, identical with that from oil of clove.

Soluble in alcohol (1 in 20).

Standard.—Oil of copaiba has a specific gravity of 0.895 to 0.908. Optical rotation, -7° to -35° . Refractive index at 20° , 1.495 to 1.500. A solution of 1 millilitre of the oil in 5 millilitres of glacial acetic acid does not develop more than a faint reddish or purple colouration on the addition of 4 drops of nitric acid (absence of gurjun oil). When distilled under reduced pressure, the first 10 per cent. of the distillate has an optical rotation lower than that of the original oil (absence of oil of African copaiba).

Action and Uses.—Oil of copaiba resembles copaiba in its action. It may be administered in capsules or as an emulsion.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

OLEUM CORIANDRI

(Ol. Coriand.)

Oil of Coriander

Oil of coriander is obtained by distillation from coriander. It occurs as a colourless or pale yellow liquid with a characteristic, aromatic odour and a warm, spicy taste. Oil of coriander **contains** coriandrol, $C_{10}H_{17}OH$, the dextro-isomeride of linalol, which has a specific gravity of 0.868,

boils at 194° to 198°, and may occur to the extent of 45 to 65 per cent.; on oxidation it yields citral and may be converted into geraniol. Other constituents of the oil are *d*-pinene, *β*-pinene, terpinene, decyl aldehyde, geraniol and borneol. The characteristic odour of the oil is due to a body not yet identified. Oil of coriander should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (2 in 1).

Standard, B.P.—Oil of coriander has a specific gravity of 0·870 to 0·884. Optical rotation, +8° to +15°. Refractive index at 20°, 1·462 to 1·472. It is soluble in 3 volumes of alcohol (70 per cent.; specific gravity, 0·8896 to 0·8901).

Action and Uses.—Oil of coriander is aromatic, stimulant and carminative. It is added to purgative medicines to diminish the tendency to griping.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

OLEUM CROTONIS

(Ol. Croton.)

Croton Oil

Croton oil is obtained from the seeds of *Croton Tiglium* Linn., indigenous to the Malabar Coast and cultivated in Southern Asia and China. The oil is expressed in India or England. It occurs as an amber-yellow, orange, or brown, viscid liquid, having a nauseous odour and a taste at first mild, but afterwards sharp and acrid. It is a weak drying oil and thickens somewhat on exposure to the air. It is slightly dextrorotatory. It has been stated to **contain** the glycerides of stearic, palmitic, myristic, lauric, valeric, butyric, acetic, formic, oleic, linolic and tiglic acids. The active constituent is a powerfully vesicant substance, named croton-resin, which is believed to be a lactone of complicated structure. It is a hard, pale yellow, brittle substance, nearly insoluble in water, light petroleum and benzene, but readily soluble in alcohol, ether and chloroform. It has neither basic nor acidic properties, but produces, on oxidation with nitric acid, a mixture of acids. The vesicating power of the resin is destroyed by boiling with alkalis, or by hydrogenation.

Soluble in less than one volume of dehydrated alcohol forming a clear solution; with an equal volume the solution is turbid, and more alcohol causes complete separation into two layers, the vesicating constituent being contained in the alcoholic solution. The solubility in alcohol appears to depend upon the proportion of free acids present, and increases with the age of the oil. Freely soluble in light petroleum, ether, chloroform, carbon disulphide, and fixed and volatile oils. Completely soluble in glacial acetic acid at ordinary temperatures

Standard.—Croton oil has a specific gravity of 0.940 to 0.955. Refractive index at 40°, 1.470 to 1.473. Saponification value, 205 to 220. Iodine value, 102 to 118. It thickens slightly, but does not solidify either completely or partially, when vigorously shaken with half its volume of fuming nitric acid and the same proportion of water (limit of other non-drying oils). It is soluble in all proportions of light petroleum (limit of castor oil).

Action and Uses.—Croton oil is an extremely powerful cathartic; except in very small doses it is a powerful irritant of the stomach and intestines, causing violent vomiting and purging, followed by collapse. It must, therefore, be used with great care, and is contra-indicated in feeble subjects, where there is organic obstruction, or in inflammatory conditions of the stomach and intestine. It is sometimes administered as a purgative in cases of mental derangement showing violence. Its use may be followed by the appearance of a pustular eruption. The oil is **administered** on sugar, or mixed with butter. Externally, croton oil is a powerful counter-irritant and vesicant; it is used in the form of *Linimentum Crotonis*.

Dose.—0.03 to 0.06 millilitre ($\frac{1}{2}$ to 1 minim).

Preparation

Linimentum Crotonis, B.P.C.—(*Lin. Croton.*)—Liniment of Croton Oil. Croton oil, about 1 in 8, with oil of cajuput and alcohol (90 per cent.).

This liniment was included in the British Pharmacopœia, 1914.

OLEUM CUBEBAE

(*Ol. Cubeb.*)

Oil of Cubeb

Oil of cubeb is obtained by steam distillation from the coarsely ground fruit of *Piper Cubeba* Linn. It occurs as a colourless, pale yellow or bluish-green liquid, having the characteristic odour and warm, camphoraceous taste of cubeb. The green colour of the oil is not due to the presence of copper, as is frequently supposed, but to a blue fraction containing azulene. The oil **consists** mainly, if not wholly, of terpenes and sesquiterpenes. Dipentene, $C_{10}H_{16}$, a lævorotatory terpene (optical rotation, -35.5°), presumably pinene or camphene, and two sesquiterpenes, one identical with cadinene, $C_{15}H_{24}$, are present. Cubeb camphor which occurs in oil distilled from old cubeb, appears to be a crystalline sesquiterpene alcohol, derived from the sesquiterpenes by hydration and having the formula, $C_{15}H_{25}OH$. It is lævorotatory, crystallising in rhombic form and melting at 65° to 70° . It is somewhat unstable, decomposing, when kept over sulphuric acid, into sesquiterpene and water.

Soluble in alcohol (90 per cent.) (1 in about 18) and in all proportions of dehydrated alcohol.

Standard.—Not less than 60 per cent. of oil of cubeb distils between 250° and 280°. Specific gravity, 0·910 to 0·930. Optical rotation, –20° to –35°. Refractive index at 20°, 1·480 to 1·502.

Action and Uses.—Oil of cubeb has properties resembling those of copaiba. It is employed internally, as a stimulating antiseptic to the bronchial and genito-urinary mucous membranes, in chronic bronchitis, gonorrhœa and cystitis. It is excreted by the bronchioles, kidneys and skin. The oil may be **administered** as an emulsion or in capsules. It is inhaled from hot water in the treatment of chronic bronchitis. Oleo-resin of cubeb has the stimulant and diuretic properties of the oil and is sometimes preferred; it is usually dispensed in capsules.

Dose. 0·3 to 1·2 millilitres (5 to 20 minims).

OLEUM CUMINI

(Ol. Cumin.)

Oil of Cummin

Oil of cummin is obtained by distillation from the fruits of *Cuminum Cymimum* Linn., a native of Egypt and the Mediterranean countries, and cultivated in Arabia, India and China. The oil is colourless or pale yellow when freshly distilled, but becomes darker on keeping. It has an unpleasant, characteristic odour, and a spicy, somewhat bitter taste. Oil of cummin **contains** cuminic or cumic aldehyde, *p*-isopropylbenzaldehyde (30 to 35 per cent.). The hydrocarbons consist of *p*-cymene, β -pinene and dipentene. β -phellandrene and a hydrogenated cuminic alcohol are probably present.

Standard.—Oil of cummin contains not less than 30 per cent. w/w of cuminic aldehyde, $C_{10}H_{12}O$. Specific gravity, 0·900 to 0·935. Optical rotation, +3° to +8°. Refractive index at 20°, 1·495 to 1·509. It is soluble in 10 volumes of alcohol (80 per cent.; specific gravity, 0·8634 to 0·8640).

Assay.—Weigh accurately into a stoppered tube about 1·5 grammes of oil; add 12 millilitres of N/2 hydroxylamine hydrochloride reagent prepared with 60 per cent. alcohol, and 1 drop of methyl orange indicator; shake well, and titrate with N/2 alcoholic potassium hydroxide; each millilitre of N/2 alcoholic potassium hydroxide is equivalent to 0·0743 gramme of $C_{10}H_{12}O$, which allows for the correcting factor for methyl orange.

Action and Uses.—Oil of cummin has a carminative action: it is used chiefly in veterinary medicine.

OLEUM EUCALYPTI(Ol. *Eucalyp.*)**Oil of Eucalyptus**

Oil of eucalyptus is obtained by rectifying the oil distilled from the fresh leaves of *Eucalyptus polybractea* R. T. Baker, *E. dumosa* A. Cunn., and other species of *Eucalyptus* which yield oils containing a large proportion of cineole and but little phellandrene. It occurs as a colourless or pale yellow liquid, with an aromatic, camphoraceous odour and a pungent, camphoraceous taste followed by a sensation of coldness. Oil of eucalyptus **contains** chiefly cineole, $C_{10}H_{18}O$, also known as eucalyptol or cajuputol. Other constituents are *d*-pinene and other terpenes, and various alcohols, aldehydes and esters; phellandrene may also be present in small quantities. "Lemon-scented" eucalyptus oil is obtained from *E. maculata* var. *citriodora* Hook. and contains about 70 per cent. of citronellal. The oil of *E. dives* contains a large proportion of piperitone and is used in the manufacture of thymol. The unmixed oil of *E. Globulus* Labill. is no longer a commercial article. Oil of eucalyptus should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (3 in 1 or less); very slightly soluble in water; miscible in all proportions with dehydrated alcohol, oils, fats and paraffins.

Standard, B.P.—Oil of eucalyptus contains not less than 70 per cent. w/w of cineole, $C_{10}H_{18}O$. Specific gravity, 0.910 to 0.930. Optical rotation, 5° to $+5^{\circ}$. Refractive index at 20° , 1.458 to 1.470. It is soluble in 5 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901). It complies also with limit tests for phellandrene and for aldehydes.

Action and Uses.—Oil of eucalyptus is employed as an antiseptic and deodorant. Internally, it is given in catarrhal inflammation of mucous membranes, especially of the respiratory tract and bladder. Pastilles containing the oil, often with menthol or red gum, are much used in catarrhal colds with sore throat. The oil is sprinkled on the handkerchief and inhaled frequently for catarrhal colds and to prevent infection. Mixed with menthol, camphor, or pine oil it can be inhaled from a "dry" inhaler. The oil is inhaled with steam, sometimes with the addition of menthol, oil of pine and compound tincture of benzoin, to relieve cough in chronic bronchitis and asthma. Oily spray solutions and ointments for use in catarrh are prepared with eucalyptus and pine oils and other ingredients, such as cocaine, menthol, or camphor. It is used in bougies, suppositories and pessaries as an antiseptic and to disguise the smell of iodoform. An ointment containing the oil in soft paraffin (1 in 50) is employed in the treatment of burns as a mild antiseptic dressing. The oil may be administered in capsules or as an emulsion.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM EUCALYPTI CHLORINATUM.—Chlorinated oil of eucalyptus may be prepared by treating oil of eucalyptus with potassium chlorate and hydrochloric acid; place oil of eucalyptus, 20 parts, in a wide-mouthed glass bottle, add potassium chlorate, 0·5 part, and hydrochloric acid, 0·5 part, and allow the mixture to stand for about five minutes; add hydrochloric acid, 1·5 parts, in three portions at intervals of about five minutes; shake the mixture in a separator with a slight excess of sodium carbonate solution, separate the chlorinated product, wash it with water until free from alkali, and dry it by means of anhydrous calcium chloride. Chlorinated oil of eucalyptus is used as a solvent for dichloramine.

Preparations

Nebula Eucalypti, B.P.C.—(Neb. Eucalyp.)—Eucalyptus Spray. Oil of eucalyptus, 5 per cent. v/v, in light liquid paraffin.

Unguentum Eucalypti, B.P.C.—(Ung. Eucalyp.)—Eucalyptus Ointment. Eucalyptus oil, 10 per cent., in hard and soft paraffins.

This ointment was included in the British Pharmacopœia, 1914.

Vapor Eucalypti Compositus, B.P.C.—(Vap. Eucalyp. Co.)—Compound Eucalyptus Inhalation. *Syn.*—Anti-catarrhal Salts. Phenol, oil of eucalyptus, and camphor, of each about 1 in 6, oil of Siberian fir and strong solution of iodine, of each about 1 in 12, in ammoniated alcohol.

OLEUM FÆNICULI

(Ol. Fœnic.)

Oil of Fennel

Oil of fennel is obtained by distillation from the dried, ripe fruit of *Fœniculum vulgare* Mill. It occurs as a colourless or slightly yellow liquid, having the characteristic, aromatic odour of fennel and a taste at first bitter and camphoraceous, but afterwards sweetish. The characteristic fennel odour is due to the anethole and fenchone it contains. The chief and most valuable **constituent** of the oil is anethole which crystallises out in the cold. It also contains fenchone, $C_{10}H_{16}O$, a ketone isomeric with camphor and strongly dextrorotatory. The following bodies may also be present in the oil:—Fenchol, *d*-pinene, dipentene, phellandrene and limonene. It should be **stored** in well-stoppered, amber-coloured bottles.

Soluble in alcohol (1 in 5 to 1 in 3).

Standard.—Oil of fennel, determined by the method of the British Pharmacopœia for Oleum Anisi, employing a crystal of congealed oil of anise to start crystallisation instead of previously solidified oil of fennel, has a freezing-point not below 3°. Specific gravity, 0·960 to 1·000. Optical rotation, +4° to +24°. Refractive index at 20°, 1·525 to 1·550. A solution in 8 parts of alcohol (80 per cent.; specific gravity, 0·8634 to 0·8640) is neutral to litmus and is not coloured on the addition of a few drops of ferric chloride solution (limit of oils containing phenols).

Action and Uses.—Oil of fennel is an aromatic carminative, and is employed with purgative medicines to prevent gripe and as Aqua Fœniculi in the intestinal colic of children.

Dose.—0·03 to 0·2 millilitre ($\frac{1}{2}$ to 3 minims).

OLEUM GERANII

(Ol. Geran.)

Oil of Geranium

Synonyms—Oil of Rose Geranium; Oil of Pelargonium.

Oil of geranium is obtained by distillation from the leaves of *Pelargonium odoratissimum* Ait., *P. capitatum* Ait., and *P. Radula* L'Hérit., the plants being cultivated for the purpose in France, Algiers, Spain, Réunion (Bourbon), and Corsica. The oil is found in all green parts of the plants, but the greatest yield is obtained from the leaves. It occurs as a colourless, greenish, or brownish liquid, with a pleasant, rose-like odour. The ester percentage, calculated as geranyl tiglate, in French oils lies between 22 and 29 per cent., in Algerian oils, between 21 and 30 per cent., and in Bourbon oils, usually between 26 and 35 per cent. This oil must not be confused with Indian geranium oil (palmarosa oil), commonly known as Turkish geranium oil, derived from *Cymbopogon Martini*, which contains 85 to 95 per cent. of geraniol and is practically devoid of esters. The chief **constituent** of the oil is geraniol, but citronellol is also present and mixtures of the two alcohols have been described as "rhodinol" and "reuniol"; linalol is present in the lower boiling fractions of the oil.

Standard.—Oil of geranium, determined by the method of the British Pharmacopœia for esters in volatile oils, contains not less than 21 per cent. of ester, calculated as geranyl tiglate; each millilitre of N/2 alcoholic potassium hydroxide is equivalent to 0·1181 gramme of geranyl tiglate, $C_{15}H_{24}O_2$. Specific gravity, (French oil) 0·895 to 0·905, (Algerian oil) 0·894 to 0·904, (Bourbon oil) 0·888 to 0·896. Optical rotation. (French oil) -7° to -11° , (Algerian oil) -7° to -12° , (Bourbon oil) -8° to -14° . Refractive index at 20° , (French oil) 1·465 to 1·470, (Algerian oil) 1·465 to 1·467, (Bourbon oil) 1·462 to 1·467. It is soluble in 3 times its volume of alcohol (70 per cent.; specific gravity, 0·8896 to 0·8901).

Uses.—Oil of geranium is largely employed in perfumery and it is frequently used instead of oil of rose for perfuming tooth powders, ointments and other preparations.

GERANIOLUM.—Geraniol, $C_{15}H_{24}OH$, occurs naturally in many essential oils and is obtained commercially mainly from palmarosa oil or from oil of citronella. It occurs as a colourless liquid with a sweet, rose-like odour, having a specific gravity

of about 0.880 and a boiling-point of about 228° to 230°. It is largely used in perfumery.

GERANYLIS ACETAS.—Geranyl acetate, $\text{CH}_3\cdot\text{COOC}_{10}\text{H}_{17}$, occurs in many essential oils and may be obtained by the esterification of geraniol with acetic acid. It occurs as a colourless liquid with a sweet, lavender-like odour, and has a specific gravity of about 0.917 and a boiling-point of about 242° to 245°. It is largely used in perfumery.

OLEUM GOSSYPII SEMINIS

(*Ol. Gossyp. Sem.*)

Cottonseed Oil

Cottonseed oil is obtained by expression from the seeds of *Gossypium herbaceum* Linn. and other species of *Gossypium* (Fam. Malvaceæ), the plants being extensively cultivated in the United States of America, Egypt and India. It is refined by a process of partial saponification whereby the dark red colouring matter of the crude oil is carried down as a precipitate by the soap, leaving a pale supernatant oil. Cottonseed oil is a typical semi-drying oil; it occurs as a pale yellow or yellow, almost odourless liquid, with a bland, nutty taste. On cooling cottonseed oil, particles of solid fat separate; they should be re-melted and the oil thoroughly mixed before any of it is used. Cottonseed oil may be identified and its presence in other oils detected, provided it has not been previously heated to 200°, by means of the following colour reaction, which is known as the Halphen test:—The oil is mixed with an equal volume of a mixture containing equal proportions of amyl alcohol and a 1 per cent. w/v solution of precipitated sulphur in carbon disulphide; on heating the mixture in a securely-closed strong-walled tube by partial immersion in boiling water, a pink colouration appears in mixtures containing 5 per cent. or less of cottonseed oil in from ten to fifteen minutes. When cottonseed oil is shaken with an equal volume of nitric acid of specific gravity 1.375 and allowed to stand for some time, up to twenty-four hours, a characteristic, coffee-brown colouration is produced. Cottonseed oil **contains** the glycerides of palmitic, stearic, oleic and linolic acids.

Standard, B.P.—Cottonseed oil has a specific gravity of 0.920 to 0.925. Refractive index at 40°, 1.4645 to 1.4655. Acid value, not more than 0.5. Saponification value, 190 to 198. Iodine value, 103 to 115. Particles of solid fat separate at temperatures below 12°, and the oil congeals at temperatures between 0° and –5°. It complies also with tests for the absence of alkali, sesame oil and arachis oil.

Action and Uses.—Cottonseed oil is employed similarly to olive oil in preparations for external use. It may be sterilised by heating at 150° for one hour. High grade cottonseed oil is largely used as salad oil.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

OLEUM GRAMINIS CITRATI

(Ol. Gram. Citrat.)

Oil of Lemon Grass*Synonyms*—Indian Oil of Verbena; Indian Melissa Oil.

Oil of lemon grass is obtained by distillation from *Cymbopogon citratus* Stapf and *C. flexuosus* Stapf, the former being widely cultivated in India, Ceylon, the Straits Settlements, West Indies and other tropical countries, and the latter being indigenous to India. This oil is used largely under the name of oil of verbena. True oil of verbena is obtained from *Lippia citriodora* H. B. and K., which is cultivated in the South of France. The oil is distilled from the leaves and contains less citral, but has a much more delicate odour than oil of lemon grass, from which it should be distinguished. Oil of lemon grass occurs as a reddish-yellow or brownish-red, mobile liquid, having a very strong odour, resembling that of verbena. West Indian oil is lighter (specific gravity, 0.878 to 0.882), although it contains a high percentage of citral; it is less soluble in alcohol owing to the presence of an olefinic terpene which rapidly resinifies. Oil of lemon grass **contains** citral, $C_{10}H_{16}O$, an optically inactive aldehyde, which may be present to the extent of 75 to 85 per cent. The oil also contains traces of an isomeride of citral, geraniol, $C_{10}H_{18}O$, methylheptenone, $C_8H_{14}O$, traces of citronellal, $C_{10}H_{18}O$, possibly linalol, and the terpenes limonene and dipentene, together with a trace of cymene.

Standard.—Oil of lemon grass, determined by the method of the British Pharmacopœia for aldehydes in Oleum Cinnamomi, contains not less than 75 per cent. w/w of citral, $C_{10}H_{16}O$; each millilitre of N/2 potassium hydroxide in alcohol (60 per cent.) is equivalent to 0.07667 gramme of citral. Specific gravity, 0.895 to 0.908. Optical rotation, -4° to $+1^\circ$. Refractive index at 20° , 1.483 to 1.489. It is soluble in three times its volume of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901), sometimes becoming opalescent on dilution to 10 volumes.

Action and Uses.—Oil of lemon grass was formerly given internally as a carminative; it is now used mainly in perfumery and as a source of citral.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

CITRALUM.—Citral, or geranaldehyde, is a mixture of two isomeric aldehydes of the formula $C_{10}H_{16}O$, and is the characteristic odorous substance in oil of lemon. It occurs in numerous essential oils and is obtained commercially from oil of lemon grass. It occurs as a pale yellow oil, having a specific gravity of about 0.897 and a boiling-point of 224° to 228° . It is occasionally employed in perfumery, but its principal use is as the starting-point for the manufacture of ionone.

OLEUM HIPPOGLOSSI

(Ol. Hippogloss.)

Halibut-liver Oil

Halibut-liver oil is the oil obtained from the liver of the halibut, *Hippoglossus hippoglossus* Linn. It cannot be obtained in any quantity by steaming the livers as in the case of cod-liver oil, but may be prepared by extracting the dried livers with a volatile solvent and removing the solvent at a low temperature. It occurs as a pale yellow oil, with a slightly fishy odour and taste. The important characteristic of halibut-liver oil is its high content of vitamin A, of which it may contain 100 times as much as cod-liver oil, or even more. It usually contains about 2000 units of vitamin D per gramme. The following are the usual analytical figures:—Specific gravity, 0.922 to 0.925; refractive index at 40°, 1.470 to 1.478; saponification value, 170 to 180; iodine value, 120 to 136; unsaponifiable matter, 8 to 13 per cent.; blue value (antimony trichloride colour test), 400 to 3000. It is frequently adjusted by the addition of cod-liver oil or a suitable vegetable oil in order to produce a product of lower and more uniform vitamin A content, containing about 60 times that of cod-liver oil; vitamin D is also added to raise the vitamin D content to about 250 times that of cod-liver oil.

Action and Uses.—Halibut-liver oil is used in place of cod-liver oil as a means of administering the vitamins A and D. It may be **administered** in capsules or in association with malt extract.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

OLEUM HYDNOCARPI

(Ol. Hydnocarp.)

Hydnocarpus Oil

Hydnocarpus oil is a fatty oil obtained by cold expression from the fresh, ripe seeds of *Hydnocarpus Wightiana* Blume, a native of India. It occurs as a yellowish or brownish-yellow oil, or as a soft, cream-coloured fat. It has a slight, characteristic odour and a somewhat acrid taste. Hydnocarpus oil **contains** the glycerides of chaulmoogric acid, $C_{18}H_{32}O_2$, and of hydnocarpic acid, $C_{16}H_{28}O_2$, which differ in structure from the acids usually occurring in oils and fats by containing a partly reduced cyclopentane nucleus with a side chain of many carbon atoms. Hydnocarpus oil should be **stored** in well-closed containers in a cool place and protected from light.

Partly **soluble** in cold alcohol (90 per cent.); almost completely soluble in hot alcohol (90 per cent.); miscible with ether, chloroform and carbon disulphide.

Standard, B.P.—Hydnocarpus oil has a specific gravity (25°/25°) of 0.950 to 0.960. Melting-point, 20° to 25°. Specific rotation in a 10 per cent. w/v solution in chloroform, not less than +53°. Refractive index at 40°, 1.472 to 1.476. Acid value, not more than 25. Saponification value, 198 to 204. Iodine value, 97 to 103.

Action and Uses.—Hydnocarpus oil has properties similar to those of chaulmoogra oil, and has almost entirely replaced the latter in the treatment of leprosy. It is **administered** orally and by injection, 3 per cent. of creosote being sometimes added as an antiseptic. Hydnocarpus oil for **injection** may be sterilised by heating at 150° for one hour.

Dose.—0.3 to 1 millilitre (5 to 15 minims) increased gradually to 4 millilitres (60 minims), by the mouth; 2 millilitres (30 minims) increased gradually to 5 millilitres (75 minims), by subcutaneous and intramuscular injection.

OLEUM HYDNOCARPI ÆTHYLICUM

(Ol. Hydnocarp. Æth.)

Ethyl Esters of Hydnocarpus Oil

Ethyl esters of hydnocarpus oil may be prepared by direct or indirect esterification of the total acids of hydnocarpus oil. The crude mixture of ethyl esters is washed with a solution of sodium carbonate and purified by distillation under reduced pressure. It occurs as a colourless or faintly yellow, limpid oil, with a characteristic odour and a slightly acrid taste. The esterified oil of *Hydnocarpus anthelmintica* Pierre, used in Siam and China, and ethyl chaulmoograte are products analogous to ethyl esters of hydnocarpus oil and are used for the same purposes. They are derived from oils allied to that of *H. Wightiana* and are indistinguishable in appearance, odour and taste from the official esterified oil, but differ from it chiefly in having a somewhat lower optical rotation and iodine number. Ethyl esters of hydnocarpus oil **contains** the ethyl esters of chaulmoogric and hydnocarpic acids. It should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in not less than 6 volumes of cold alcohol (90 per cent.); miscible with ether, chloroform and carbon disulphide.

Standard, B.P.—Ethyl esters of hydnocarpus oil has a specific gravity of 0.905 to 0.910. Optical rotation, not less than +45°. Refractive index at 20°, 1.458 to 1.462. Acid value, not greater than 1.0. Saponification value, 190 to 196. Iodine value, 88 to 94.

Action and Uses.—Ethyl esters of hydnocarpus oil has the properties of hydnocarpus oil and is generally preferred to the latter in the treatment of leprosy. It is **administered** intravenously, intramuscularly, or subcutaneously. Ethyl esters of hydnocarpus oil for **injection** may be sterilised by heating in an autoclave or by tyndallisation.

Dose.—0.3 to 1 millilitre (5 to 15 minims), increased gradually to 4 millilitres (60 minims), by the mouth; 2 millilitres (30 minims), increased gradually to 5 millilitres (75 minims), by subcutaneous and intramuscular injection.

OLEUM JUNIPERI

(Ol. Junip.)

Oil of Juniper

Oil of juniper (English oil) consists of the entire distillate from the dried, ripe fruit of *Juniperus communis* Linn. and possesses to a high degree the characteristic odour and flavour of the crushed fruit. Foreign oil (Hungarian oil), which contains a larger proportion of the lighter constituents, has a less pronounced juniper odour and flavour. Commercial oil of juniper (so called), a third quality, is obtained as a by-product in the manufacture of an alcoholic liqueur (Borowicka) and of a juniper extract, for which there is a considerable demand. The physical and chemical tests for this product conform so closely to those of normal juniper oil that it is largely used to replace the latter; it may, however, be distinguished by its odour, which is more like turpentine than juniper. The commercial oil is sometimes distilled from a mixture of fruit obtained from *Juniperus Oxycedrus* and *J. communis*. Oil of juniper is a colourless or pale greenish-yellow, limpid liquid, with a characteristic odour and a burning, somewhat bitter taste. It contains pinene, $C_{10}H_{16}$, camphene, $C_{10}H_{16}$, cadinene, $C_{15}H_{24}$, terpinenol, $C_{10}H_{18}OH$, and juniper camphor, a crystalline body, which is probably an alcohol of the terpene series. The characteristic odour of juniper is due to a substance which has not been identified.

Soluble, when freshly distilled, in 4 volumes of alcohol (95 per cent.) with not more than a slight opalescence. The oil becomes less soluble and more viscid on storing; miscible in all proportions with chloroform, benzene, carbon disulphide and amyl alcohol.

Standard.—Oil of juniper has a specific gravity of (English oil) 0.870 to 0.890, (Hungarian oil) 0.865 to 0.895. Optical rotation, (English oil) $+1^{\circ}$ to -10° , (Hungarian oil) -5° to -15° . Refractive index at 20° , (English oil) 1.476 to 1.479, (Hungarian oil) 1.479 to 1.484.

Action and Uses.—Oil of juniper is employed chiefly as a diuretic and urinary antiseptic, but it should not be given when there is renal disease. It is also used as a carminative in flatulence and colic and in the treatment of lumbago. Its irritant properties during excretion cause reflex contractions of the uterus, and the drug has been used as an emmenagogue. The oil is **administered** on sugar, or in capsules, or as Spiritus Juniperi.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

Preparation

Spiritus Juniperi, B.P.C.—(Sp. Junip.)—Spirit of Juniper. Oil of juniper, 1 in 10, in alcohol (90 per cent.). Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopœia, 1914.

OLEUM LAVANDULÆ

(Ol. Lavand.)

Oil of Lavender

Oil of lavender is obtained by distillation from the fresh flowering tops of *Lavandula officinalis* Chaix, a plant cultivated in England, France and elsewhere. It occurs as a colourless, pale yellow or yellowish-green liquid, having the fragrant odour of the flowers and a pungent, slightly bitter taste. Oil of lavender **contains** chiefly the alcohol linalol, $C_{10}H_{18}O$, and its acetic ester, linalyl acetate; other constituents are pinene, limonene, geraniol and a sesquiterpene. Cineole occurs in some quantity in English oil, but only in traces in French oil. English oil, which undoubtedly has the finer odour, contains but little linalyl acetate, but the fineness and value of French oils appear to stand in direct ratio to the amount of linalyl acetate present. The English oil is sometimes described as being easily distinguishable from the French by its cineole-like odour. The usual adulterants of oil of lavender are oil of spike lavender and artificial esters such as ethyl citrate and ethyl phthalate. Oil of spike lavender decreases the ester content and increases the percentage of cineole. Oil of lavender should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in all proportions of alcohol (90 per cent.).

Standard, B.P.—Oil of lavender (English oil) contains not less than 7 per cent. and not more than 14 per cent. w/w, and oil of lavender (foreign oil) contains not less than 35 per cent. w/w of esters, calculated as linalyl acetate, $C_{12}H_{20}O_2$. Specific gravity, (English oil) 0·882 to 0·900, (foreign oil) 0·883 to 0·895. Optical rotation, (English oil) -3° to -10° , (foreign oil) -3° to -10° . Refractive index at 20° , (English oil) 1·459 to 1·470, (foreign oil) 1·459 to 1·464. It is soluble in 4 volumes of alcohol (70 per cent.; specific gravity, 0·8896 to 0·8901), the solution being not more than slightly opalescent.

Action and Uses.—Oil of lavender has carminative properties but is not much employed internally except as a flavouring agent; the oil itself, or Spiritus Lavandulæ, may be **administered** on sugar in flatulence and colic; lavender lozenges are employed as a mild stimulant and for their pleasant taste. Tinctura Lavandulæ Composita is used as a carminative and antispasmodic and as a colouring and flavouring agent. Oil of lavender is largely employed in perfumery and is used occasionally to cover disagreeable odours in ointments and other preparations. The

oil is used as an insect repellent and, for this purpose, is smeared on exposed parts of the skin.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

Preparations

Spiritus Lavandulæ, B.P.C.—(Sp. Lavand.)—Spirit of Lavender. Oil of lavender, 1 in 10, in alcohol (90 per cent.). Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopœia, 1914.

Spiritus Lavandulæ Compositus, B.P.C.—(Sp. Lavand. Co.)—Compound Spirit of Lavender. *Syn.*—Aqua Lavandulæ. Oils of lavender, bergamot, clove, peppermint and rose, with spirit of nitrous ether, alcohol (90 per cent.) and distilled water.

Tinctura Lavandulæ Composita, B.P.C.—(Tinct. Lavand. Co.)—Compound Tincture of Lavender. Oil of lavender, 1 in 200, with oil of rosemary, cinnamon, nutmeg and red sanders wood. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

OLEUM LAVANDULÆ SPICATÆ

(Ol. Lavand. Spic.)

Oil of Spike Lavender

Oil of spike lavender is the oil obtained by distillation from the flowering herb, *Lavandula latifolia* Vill., and other species of *Lavandula*, which grow in the lower mountainous and hilly coastal districts of France, Spain and Italy. It occurs as a colourless or pale yellow liquid, having an odour of lavender combined with that of cineole. It contains linalol, camphor, borneol, cineole (about 33 per cent.), terpineol, *d*-camphene and a sesquiterpene.

Standard.—Oil of spike lavender, determined by the method of the British Pharmacopœia for the determination of free alcohols in volatile oils, contains not less than 30 per cent. of free alcohols, calculated as linalol, using the factor, $y = 154\cdot1$. Specific gravity, 0·900 to 0·920. Optical rotation, -4° to $+6^{\circ}$. Refractive index at 20° , 1·462 to 1·469. It is soluble in 3 volumes of alcohol (70 per cent.; specific gravity, 0·8896 to 0·8901) and in 6 volumes of alcohol (65 per cent.; specific gravity, 0·9018 to 0·9022).

Action and Uses.—Oil of spike lavender resembles oil of lavender in its properties. It is often used in perfumery for the same purposes and as an application to the exposed parts of the skin to prevent insect bites.

OLEUM LIMONIS

(Ol. Limon.)

Oil of Lemon

Oil of lemon is obtained by expression from lemon peel. It occurs as a pale yellow or greenish-yellow liquid, with a characteristic odour and a warm, aromatic, slightly bitter taste. Oil of lemon **contains** chiefly *d*-limonene, which together with terpinene and phellandrene forms about 90 per cent. of the bulk of the oil. The valuable portion of the oil is the remaining 10 per cent. which contains oxygenated bodies, chiefly the aldehyde citral, $C_{10}H_{16}O$, to which the odour of the oil is largely due. The oxygenated bodies have a flavouring power much greater than that of the oil but inferior in quality. Citral boils at 224° to 228° and has a specific gravity of 0.895 to 0.899; on reduction it yields geraniol. Other oxygenated constituents are citronellal, $C_{10}H_{18}O$, geranyl acetate, about 1 per cent. and, in Palermo oil, linalyl acetate, $C_{12}H_{20}O_2$. From the stearoptene found in the oil, two crystalline substances have been isolated, one a yellow, crystalline body, $C_{14}H_{14}O_6$, melting-point, 115° ; the other a white, crystalline solid, $C_{10}H_{10}O_4$, melting-point, 144° . Adulteration with turpentine oils decreases the optical rotation; turpentine may also be detected in the first fraction of about 10 per cent., since pinene, its chief constituent, boils at 156° whereas pure oil of lemon begins to boil at about 173° . Other forms of adulteration are exceedingly difficult to detect, such as admixture with terpenes and low-grade orange oil, and sometimes citral obtained from oil of lemon grass. Determinations of citral can only give approximate results and the result is no proof of the quality of the oil. The non volatile residue is usually from 2 to 3 per cent. w/w. Oil of lemon should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (1 in 12), but the solution is frequently opalescent, owing to the presence of gummy constituents or stearoptenes; miscible in all proportions with dehydrated alcohol, ether, chloroform, benzene, amyl alcohol and glacial acetic acid; solutions in carbon disulphide or benzene are usually somewhat cloudy on account of a little water contained in the oil.

Standard, B.P.—Oil of lemon contains not less than 4 per cent. w/w of aldehydes, calculated as citral, $C_{10}H_{16}O$. Specific gravity, 0.857 to 0.861. Optical rotation, $+57^{\circ}$ to $+65^{\circ}$. Refractive index at 20° , 1.474 to 1.476.

Action and Uses.—Oil of lemon has carminative properties, but is seldom employed internally except as a flavouring agent. It is also known as essence of lemon. For culinary purposes an alcoholic solution (1 in 10) is sometimes sold as "essence of lemon," but this should be distinguished as "prepared essence of lemon."

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM LIMONIS DETERPENATUM

(Ol. Limon. Deterpenat.)

Terpeneless Oil of Lemon

Terpeneless oil of lemon is prepared by concentrating oil of lemon *in vacuo* until nearly all the terpenes have been removed, and rectifying the product by steam distillation. A more soluble oil may be prepared by further fractional distillation, whereby the sesquiterpenes are also removed. This more soluble oil is known as "terpene- and sesquiterpene-free." Terpeneless oil of lemon consists mainly of citral, with considerable quantities of esters, chiefly geranyl and linalyl acetates.

Standard.—Terpeneless oil of lemon, determined by the method of the British Pharmacopœia for aldehydes in Oleum Limonis, using 1 gramme for the determination, contains not less than 40 per cent. and not more than 50 per cent. w/w of citral. Specific gravity, 0.890 to 0.905. Optical rotation, -4° to -9° . Refractive index at 20° , 1.479 to 1.483. It is soluble in 3 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640).

Uses.—Terpeneless oil of lemon is used almost exclusively as a flavouring agent, and has the advantages of being stronger in flavour and perfume than the natural oil and more readily soluble. One fluid ounce of the terpeneless oil is equivalent in flavour to about twenty fluid ounces of oil of lemon; a 1 per cent. v/v solution in alcohol (70 per cent.) is generally used for culinary purposes.

OLEUM LINI

(Ol. Lini)

Linseed Oil

Linseed oil is obtained by cold expression from linseed, and subsequent clarification. It occurs as a yellowish-brown liquid, with a faint, characteristic odour and a bland taste. The commercial oil often has a marked odour and an acid taste, due to oxidation from exposure to air. It gradually thickens when exposed to the air and a thin film of the oil dries to a hard, transparent varnish. It does not congeal when cooled to -20° . Linseed oil **contains** principally a mixture of the glycerides of linolic, linolenic and *isolinolenic* acids, three bodies possessing similar physical properties and described generally as linoleic acid. Other constituents are the glycerides of oleic, stearic, palmitic and myristic acids. Freedom from non-drying oils is indicated by the formation of a hard varnish on exposure to the air, and the absence of mineral oil and resin oil is indicated by the low figure for unsaponifiable matter. Boiled linseed oil is linseed oil which has been heated with litharge or other suitable "driers", such as manganse resinate, to a temperature of about

150° so that metallic salts of the fatty acids are formed and cause the oil to dry more quickly; it must not be employed in place of linseed oil.

Soluble in dehydrated alcohol (1 in 40), slightly soluble in alcohol (90 per cent.); miscible in all proportions with turpentine, ether, chloroform, carbon disulphide and light petroleum (boiling-point, 50° to 60°).

Standard, B.P.—Linseed oil has a specific gravity of 0.930 to 0.940. Refractive index at 40°, 1.4725 to 1.4750. Acid value, not more than 5.0. Saponification value, 187 to 195. Unsaponifiable matter not more than 1.5 per cent. Iodine value, 170 to 200. It complies also with tests for the absence of resin and resin oils and of cottonseed oil, sesame oil and arachis oil.

Action and Uses.—Linseed oil has been used internally as a laxative, but its taste is disagreeable. A rectal injection of 60 millilitres (2 fluid ounces) of the oil, given night and morning, has been used in the treatment of piles. It is applied externally as a soothing application for burns, especially in the form of *Linimentum Calcii Hydroxidi cum Oleo Lini*. Linseed oil has been **administered** in the form of an emulsion which in combination with diluted milk has been used as a substitute for cream. On account of the absence of the antirachitic vitamin it is inferior to *Emulsio Olei Arachis* [Marylebone cream (improved)]. Linseed oil and boiled linseed oil are used largely in the arts as drying oils.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Preparation

Linimentum Calcii Hydroxidi cum Oleo Lini, B.P.C.—(*Lin. Calc. Hydrox. c. Ol. Lini*)—Liniment of Calcium Hydroxide with Linseed Oil. *Syn.*—Lime Water and Oil; Carron Oil; *Linimentum Calcis cum Oleo Lini*. Linseed oil and solution of calcium hydroxide, equal parts.

OLEUM MENTHÆ PIPERITÆ

(*Ol. Ment. Pip.*)

Oil of Peppermint

Oil of peppermint is obtained by distillation from the fresh flowering tops of *Mentha piperita* Linn. Both the black and the white varieties are used, the former yielding more oil than the latter, but of a less delicate aroma. The oil is rectified if necessary. It occurs as a pale yellow or greenish-yellow liquid, with a characteristic odour and a pungent aromatic taste followed by a sensation of coldness in the mouth. It darkens in colour and becomes viscid on keeping. Oil of peppermint **contains** menthol, menthyl acetate, $C_{12}H_{22}O_2$, menthyl *isovalerate*, together with menthone, $C_{10}H_{18}O$, cineole, inactive pinene, *l*-limonene, cadinene, phellandrene, acetaldehyde, acetic acid, *isovaleric*

aldehyde and acid, amyl alcohol and dimethyl sulphide. On cooling to a low temperature, separation of menthol occurs, especially when a few crystals of that substance are added to start crystallisation.

Japanese and Chinese peppermint oils, obtained from *Mentha arvensis* DC. var. *piperascens* Holmes and var. *glabrata* Holmes, are the richest of all in menthol, sometimes containing 85 per cent. The oil of *M. piperita* may be distinguished from that of *M. arvensis* by the following colour reaction: Mix 3 drops of the oil with 5 millilitres of glacial acetic acid containing 0.3 per cent. v/v of nitric acid, and heat the mixture in boiling water; the oil from *M. piperita* gives a blue colouration in from one to five minutes and on heating further, the colour deepens, showing a copper-coloured fluorescence, and then fades to a golden-yellow; with Japanese oil, the mixture remains colourless. Besides the specific gravity and optical rotation, the only really useful methods of analysis are the determination of the menthol, both free and as esters, and of the menthone, the latter by reduction to menthol with sodium in a solution of the oil in alcohol. Adulteration with dementholised oil, known as menthene, is sometimes practised. The odour and taste afford the best indication of the quality of the oil and by this means it is quite possible to distinguish between English, American and Japanese oils. Many Italian and some American peppermint oils have a specific gravity up to 0.915. Oil of peppermint should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (2 in 1), the solution sometimes becoming turbid on adding more of the solvent; miscible with dehydrated alcohol.

Standard, B.P.—Oil of peppermint contains not less than 4.5 per cent. and not more than 9 per cent. w/w of esters, calculated as menthyl acetate, $C_{12}H_{22}O_2$, and not less than 46 per cent. w/w of free menthol, $C_{10}H_{20}O$. Specific gravity, 0.902 to 0.910. Optical rotation, -18° to -32° . Refractive index at 20° , 1.460 to 1.470. It is soluble in 4 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901), the solution being not more than slightly opalescent, but becoming less soluble with age. It complies also with a test distinguishing it from Japanese mint oil.

Action and Uses.—Oil of peppermint is an aromatic stimulant, and carminative. It relieves gastric and intestinal flatulence and colic, and is employed with purgatives to prevent griping. The oil acts as a local anæsthetic. Oil of peppermint may be **administered** on sugar, or in mixtures as peppermint water or spirit of peppermint. Peppermint lozenges are used as a mild carminative and for their pleasant taste. Oil of peppermint has mildly antiseptic properties and is used to flavour dental pastes, powders and washes.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

Preparations

Emulsio Menthe Piperite, B.P.C.—(Emuls. Ment. Pip.)—Emulsion of Peppermint. Oil of peppermint, 1 in 10, with tincture of quillaia and distilled water. Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

Spiritus Menthæ Piperitæ, B.P.—(Sp. Menth. Pip.)—Spirit of Peppermint.
Syn.—Essence of Peppermint. Oil of peppermint, 10 per cent. v/v, in alcohol (90 per cent.). Dose.—0.3 to 2 millilitres (5 to 30 minims).

Syrupus Menthæ Piperitæ, B.P.C.—(Syr. Menth. Pip.)—Syrup of Peppermint.
Concentrated peppermint water, 1 in 8, in syrup. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

OLEUM MENTHÆ VIRIDIS

(Ol. Menth. Vir.)

Oil of Spearmint

Synonym—Oleum Menthæ Crispæ.

Oil of spearmint is obtained by distillation from fresh, flowering spearmint, *Mentha viridis* Linn. and *M. crispa* Roth., grown in Europe and America, most of the oil of commerce being imported from North America. It occurs as a colourless, pale yellow or greenish-yellow liquid when recently distilled, but becomes darker and viscid on keeping; it has the characteristic odour and warm, slightly bitter taste of spearmint. The oil **contains** carvone, which may occur to the extent of from 42 to 60 per cent., an alcohol, *l*-limonene and *l*-pinene.

Standard.—Oil of spearmint, determined by the method of the British Pharmacopœia for Oleum Cari, contains not less than 42 per cent. of carvone. Specific gravity, 0.920 to 0.940. Optical rotation, -34° to -55° . Refractive index at 20° , 1.483 to 1.490. It is soluble in three times its volume of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340).

Action and Uses.—The properties of oil of spearmint resemble those of peppermint oil. It is used as a flavouring agent and carminative.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM MORRHUÆ

(Ol. Morrhu.)

Cod-liver Oil

Synonym—Oleum Jecoris Aselli.

Cod-liver oil is the fixed oil expressed from the fresh liver of the cod, *Gadus morrhua* Linn. (Order Teleostei), by the application of low-pressure steam at a temperature not exceeding 85° , after which it is cooled to about 0° and filtered to remove the separated fat. It occurs as a pale yellow liquid with a slightly fishy, but not rancid, odour, and a bland, slightly fishy taste. Inferior or old oils are liable to be dark-coloured, acrid or bitter, unduly acid, and more or less rancid, but if properly

stored cod-liver oil retains its potency and characters for many years; the vitamin A is rapidly destroyed on exposure to sunlight in colourless or lightly tinted glass bottles. On exposure to the air the oil absorbs a considerable amount of oxygen and becomes thicker, but does not dry to a hard varnish.

The most important medicinal constituents of the oil are the vitamins A and D, but it **contains** a large proportion of unsaturated fatty glycerides, largely those of clupanodonic acid, $C_{22}H_{34}O_2$, and of a highly unsaturated acid containing 18 or 20 carbon atoms. Glycerides of oleic acid are probably absent, but those of palmitic and stearic acids occur in small quantity. The unsaponifiable matter consists largely of cholesterol with small quantities of batyl alcohol, a hydrocarbon, and the vitamins A and D. Statements have been made that various elements, especially iodine, are present in the oil. These were probably impurities; medicinal oil at the present time contains not more than the very smallest trace of iodine. When a statement is made of the number of units of vitamin D in cod-liver oil, the unit referred to should be the unit of anti-rachitic activity (vitamin D) defined in the British Pharmacopœia. The vitamin D activity of cod-liver oil varies from about 50 to 250 units per gramme, the average being about 100 units. The vitamin A content varies very widely in different samples. An average sample of oil may contain about 2000 units per gramme, the unit being that described under *Liquor Vitaminæ-A*. The "blue value" of cod-liver oil is the number of blue tintometer units given by a 20 per cent. w/v solution of the oil in chloroform in the antimony trichloride test, calculated from the concentration of the oil which gives a reading of 5 blue units in the tintometer. The "blue value" of cod-liver oil varies from about 6 to about 50, the average being about 15. Cod-liver oil should be **stored** in completely-filled, well-closed containers and protected from light.

Slightly **soluble** in alcohol (90 per cent.); miscible with ether, light petroleum, carbon disulphide and chloroform.

Standard, B.P.—Cod-liver oil has a specific gravity of 0.922 to 0.929. Refractive index at 40°, 1.4705 to 1.4745. Acid value, not greater than 1.2. Saponification value, 180 to 190. Unsaponifiable matter, not more than 1.5 per cent. Iodine value, 155 to 173. It remains bright when maintained at 0° for three hours, and it complies with the antimony trichloride limit test for the presence of vitamin A.

Action and Uses.—Cod-liver oil is a food rather than a drug, and is the most easily assimilable of all oils. It increases weight and improves the general condition of the patient, being often well borne by those who are unable to digest fats. Not only does the oil increase the total absorption of fat but also the percentage absorption of all fats taken, and it influences favourably the retention of nitrogen. It may be that the unsaturated character of the fats is an important factor, since one function of the liver is the preparation of fatty acids in a high degree of unsaturation for the further processes of metabolism. The medicinal virtues of cod-liver oil are, however, in the main due to the relatively

large amounts of vitamin A (growth promoting and anti-infective) and vitamin D (antirachitic) present in the oil. The antirachitic factor can be produced by irradiation of ergosterol with a mercury vapour lamp; such preparations, suitably flavoured and admixed, are widely used in place of cod-liver oil and its preparations. Cod-liver oil is employed to improve nutrition and promote calcification in wasting diseases, such as tuberculosis and rickets, and in the treatment of the irritating cough due to enlarged mediastinal glands. It is of the greatest service in the malnutrition of children and is best given in the cold months of the year, since a distaste for the oil frequently arises in the summer months. It should not, moreover, be given when there is diarrhœa. Externally, the oil is sometimes applied by inunction with good results, especially to young infants. Cod-liver oil may be administered in the form of emulsion or as *Extractum Malti cum Oleo Morrhuæ* when the plain oil causes nausea. Emulsions are also prepared with the hypophosphites of calcium and sodium for use in phthisis.

Dose.— 2 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

VITAMIN A AND D CONCENTRATES.—A concentrate containing vitamin A and vitamin D may be prepared from cod-liver oil by saponification with alcoholic potash, extraction of the unsaponifiable matter with ether, and the removal of cholesterol from the ether-soluble fraction as described under *Liquor Vitaminæ-A*. An average sample of cod-liver oil contains about 2000 units of vitamin A and about 100 units of vitamin D per gramme. Since the unsaponifiable matter of cod-liver oil constitutes about 1 per cent. of the oil and the unsaponifiable fraction, with the cholesterol removed, about 0.5 per cent., the vitamin A and D potencies of a cod-liver oil concentrate is approximately 200 times that of the original oil. The vitamin A content of different samples of cod-liver oil varies very considerably and the vitamin D content may vary from about 50 to 250 units per gramme; the vitamin content of the concentrate may vary, therefore, within somewhat wide limits. The vitamin A potency of hairbut-liver oil is stated to be about 60 times that of an average cod-liver oil and the vitamin D potency about 20 times (see *Oleum Hippoglossi*). The vitamin A and D potencies of a concentrate may be determined by biological assay and some guide to the vitamin A potency may also be obtained by means of the antimony trichloride reaction (see *Liquor Vitaminæ-A*).

Solutions of vitamin A and D concentrates in arachis oil suitable for administration may be prepared, and adjusted to the required strength by the addition of vitamin A concentrate obtained from mammalian liver and calciferol or irradiated ergosterol prepared by the ultra-violet irradiation of ergosterol. Concentrates of vitamins are employed in the manufacture of certain margarines and other foodstuffs in which an added vitamin content is an advantage. They are also used to administer vitamins A and D in a more concentrated form than in cod-liver oil itself and may be given in tablets, or as *Extractum Malti cum Vitaminis* which contains about 3000 units of vitamin A and about 225 units of vitamin D in 4 millilitres (1 fluid drachm).

Preparations

Emulsio Olei Morrhuæ, B.P.C.—(*Emuls. Ol. Morrh.*)—Emulsion of Cod-Liver Oil. It contains 50 per cent. v/v of cod-liver oil. Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Emulsio Olei Morrhuæ cum Glycerophosphatibus, B.P.C.—(*Emuls. Ol. Morrh. c. Glycerophosph.*)—Emulsion of Cod-liver Oil with Glycerophosphates. It contains 50 per cent. v/v of cod-liver oil, with the glycerophosphates of calcium, iron, magnesium, potassium and sodium. Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Emulsio Olei Morrhue cum Hypophosphitibus, B.P.C.—(Emuls. Ol. Morrh. c. Hypophosph.)—Emulsion of Cod-liver Oil with Hypophosphites. *Sym.*—**Emulsio Olei Morrhue Composita**; Compound Emulsion of Cod-liver Oil. It contains 50 per cent. v/v of cod-liver oil with 1 grain each of the hypophosphites of calcium and sodium in each fluid ounce. Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Emulsio Olei Morrhue et Creosoti, B.P.C.—(Emuls. Ol. Morrh. et Creosot.)—Emulsion of Cod-liver Oil and Creosote. It contains 33.3 per cent. v/v of cod-liver oil with 4 minims of creosote in each fluid ounce. Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Extractum Malti cum Oleo Morrhue, B.P.—(Ext. Malt. c. Ol. Morrh.)—Extract of Malt with Cod-liver Oil. Cod-liver oil, 10 per cent. w/w, in extract of malt. It contains approximately 15 per cent. v/v of cod-liver oil; 16 millilitres contains about 2.5 millilitres, and 4 fluid drachms contains about 36 minims, of cod-liver oil. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

This extract was included in the British Pharmaceutical Codex, 1923.

Unguentum Zinci Morrhuatæ, B.P.C.—(Ung. Zinc. Morrh.)—Zinc Morrhuate Ointment. Cod-liver oil, about 14 per cent., and zinc oxide, about 32 per cent., with solution of calcium hydroxide, purified talc and balsam of Peru, in beeswax, wool fat and white soft paraffin.

OLEUM MYRCIÆ

(Ol. Myrc.)

Oil of Bay

Oil of bay is obtained by distillation from the leaves of *Pimenta acris* Wight, and probably other closely allied species, plants flourishing in the West Indies, especially in St. Thomas, Jamaica, etc. The oil is distilled into water, where it separates into two portions—a light fraction, distilling over rapidly, and a heavy fraction, distilling more slowly, the former floating on the top of the water, the latter sinking. These are mixed to obtain a normal oil. Oil of bay occurs as a yellow liquid rapidly becoming brown on exposure to the air, having a pleasant, characteristic odour and a sharp, spicy taste. A semi-solid mass is produced when the oil is mixed with an equal volume of strong sodium hydroxide solution. On the addition of ferric chloride solution to a 2 per cent. solution of the oil in alcohol, a light green colour is produced. Oil of bay contains eugenol, $C_{10}H_{12}O_2$, myrcene, $C_{10}H_{16}$, chavicol, $C_9H_{10}O$, methyleugenol, $C_{11}H_{14}O_2$, methylchavicol, $C_{10}H_{12}O$, *l*-phellandrene, $C_{10}H_{16}$, and citral, $C_{10}H_{16}O$. Myrcene, on treatment with glacial acetic acid and sulphuric acid, yields dipentene and an oil with a lavender-like odour, which yields linalol after saponification, identified by its conversion into citral. Myrcene, therefore, bears the same relation to linalol as camphene to isoborneol, and pinene or dipentene to terpineol.

Soluble, when freshly distilled, in an equal volume of alcohol (95 per cent.) forming a clear solution which becomes cloudy on further dilution. On keeping, however, the oil becomes less soluble and it then gives only turbid mixtures with alcohol. This is due to polymerisation of the olefinic terpene, myrcene.

Standard.—Oil of bay, determined by the method of the British Pharmacopœia for eugenol in *Oleum Caryophylli*, contains not less than 45 per cent. of phenols. Specific gravity, 0.945 to 0.990. Optical rotation, 0° to -4° . Refractive index at 20° , 1.500 to 1.520.

Uses.—Oil of bay is not employed in medicine, but is used in the preparation of bay rum. The latter is used as a wash for the hair and as an astringent application to the face after shaving.

Preparation

Spiritus Myrciæ Compositus, B.P.C.—(Sp. Myrc. Co.)—Compound Spirit of Bay. *Syn.*—*Spiritus Pimentæ Compositus*; Compound Spirit of Pimento. Oil of bay, oil of orange, oil of pimento, and dry extract of quassia, in alcohol (90 per cent.) and distilled water. Preparations similar in composition are sold as bay rum.

OLEUM MYRISTICÆ

(Ol. Myrist.)

Oil of Nutmeg

Oil of nutmeg is obtained by distillation from nutmegs. It occurs as a colourless or pale yellow liquid, with a characteristic odour and a warm, spicy taste. The oil **contains** *d*-camphene, which may be present to the extent of 80 per cent.; it also contains *d*-pinene, dipentene, *d*-borneol, *l*-terpineol, geraniol, saffrole, myristicin (a methoxy derivative of saffrole), and various esters. On distillation, about 60 per cent. of the oil passes over below 180° . Oil of nutmeg closely resembles volatile oil of mace and is scarcely distinguishable from it; frequently no commercial distinction is made between the two oils. Oil of nutmeg should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of nutmeg has a specific gravity of 0.880 to 0.925. Optical rotation, $+10^{\circ}$ to $+30^{\circ}$. Refractive index at 20° , 1.474 to 1.488. Residue on rapid evaporation in a flat dish on a water-bath, not more than 3 per cent. It is soluble in 3 volumes of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340).

Action and Uses.—Oil of nutmeg has carminative properties and is used as a flavouring agent. It is mildly counter-irritant and is sometimes used in liniments and hair lotions. After absorption, the oil has greater stimulant properties on the cerebral cortex than any other oil except oil of absinth; large doses may induce epileptiform convulsions. It is **administered** on sugar, or as *Spiritus Myristicæ*, and is added to purgative pills to prevent gripe.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM MYRISTICÆ EXPRESSUM.—Expressed oil of nutmeg, *Adeps Myristicæ*, or mace butter, is a concrete oil of a bright orange colour obtained from nutmeg or mace by expression with heat. It acts as a mild stimulant when applied externally, and is sometimes added to plasters and hair lotions.

Preparation

Spiritus Myristicæ, B.P.C.—(Sp. Myrist.)—Spirit of Nutmeg. Oil of nutmeg, 1 in 10, in alcohol (90 per cent.). Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopæia, 1914.

OLEUM MYRISTICÆ DETERPENATUM

(Ol. Myrist. Deterpenat.)

Terpeneless Oil of Nutmeg

Terpeneless oil of nutmeg is oil of nutmeg concentrated *in vacuo* until reduced to about one fifth of its volume. It consists of terpineol, linalol, borneol, geraniol, myristicin, myristic acid and traces of eugenol and safrole.

Standard.—Terpeneless oil of nutmeg is soluble in 3 volumes of alcohol (80 per cent.; specific gravity, 0·8634 to 0·8640). Specific gravity, 1·040 to 1·100. Optical rotation, $+1^{\circ}$ to $+14^{\circ}$. Refractive index at 20° , 1·500 to 1·533.

Action and Uses.—Terpeneless oil of nutmeg has properties similar to those of oil of nutmeg. One fluid ounce of the terpeneless oil is equivalent in flavour to about five fluid ounces of the natural oil.

OLEUM NEROLI

(Ol. Nerol.)

Oil of Neroli

Synonyms—Oleum Aurantii Florum; Oil of Orange-flowers.

Oil of neroli is obtained by distillation with water from the fresh blossoms of the bitter-orange tree, *Citrus Aurantium* Linn. subsp. *amara* Engl., and is produced in Southern France. It occurs as a pale yellow liquid, slightly, but distinctly, fluorescent, becoming brownish-red on exposure to light, with an intense odour of orange blossoms, and having a bitter, aromatic taste. The alcoholic solution has a fine, violet-blue fluorescence. When exposed to low temperatures the oil becomes turbid and occasionally solid. Oil of neroli **contains** the methyl ester of anthranilic acid, which occurs in small quantity and to which the odour and fluorescence of the oil are due. Its odour in the undiluted state is disagreeable, but very pleasant in largely diluted solutions. Other constituents of the oil are nerol, *l*-linalol, $C_{10}H_{18}O$, linalyl acetate $C_{12}H_{20}O_2$,

geraniol, $C_{10}H_{18}O$, limonene, $C_{10}H_{16}$, and a stearoptene, called neroli camphor, which is odourless and tasteless when pure, and melts at 55° . Oil of neroli should be **stored** in small, well-stoppered, amber-coloured bottles.

Standard.—Oil of neroli is soluble in twice its volume of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640), the solution becoming turbid on the addition of more of the alcohol. Specific gravity, 0.870 to 0.885. Optical rotation, 0° to $+8^{\circ}$. Refractive index at 20° , 1.468 to 1.477. Saponification value, not more than 70.

Uses.—Oil of neroli is largely employed in perfumery. The aqueous distillate obtained in its preparation constitutes triple orange-flower water and the oil is used in the preparation of the concentrated water.

Preparations

Aqua Aurantii Floris, B.P.C.—(Aq. Aurant. Flor.)—Orange-flower water. Triple orange-flower water diluted, immediately before use, with twice its volume of distilled water.

This water was included in the British Pharmacopœia, 1914.

Aqua Aurantii Floris Concentrata, B.P.C.—(Aq. Aurant. Flor. Conc.)—Concentrated Orange-flower Water. Oil of neroli, about 1 in 170. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to orange-flower water, but contains 1.5 per cent. v/v of alcohol (90 per cent.).

Aqua Aurantii Floris Triplex, B.P.C.—(Aq. Aurant. Flor. Trip.)—Triple Orange-flower Water. The undiluted orange-flower water of commerce.

Syrupus Aurantii Floris, B.P.C.—(Syr. Aurant. Flor.)—Syrup of Orange-flower. Triple orange-flower water, 15 per cent. v/v, with sucrose and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup was included in the British Pharmacopœia, 1914.

OLEUM OLIVÆ

(Ol. Oliv.)

Olive Oil

Olive oil is obtained by expression from the ripe fruits of *Olea europæa* Linn., a small tree cultivated in Spain, France, Italy and other countries bordering on the Mediterranean, also in California and South Australia. It occurs as a pale yellow or greenish-yellow liquid, with a faint, peculiar, but not rancid, odour, and a bland taste. The green colour of some oil is due to chlorophyll. Exposed to the air the oil loses colour and becomes rancid, acquiring a disagreeable smell, a sharp taste and a thicker consistence, the changes being promoted by heat and accompanied by a large increase in the quantity of free fatty acid present in the oil. When heated to 120° , it becomes lighter in colour; at 220° it becomes nearly colourless and at the same time rancid, and at 315° it is decomposed. Other oils, such as cottonseed oil, arachis oil, tea-seed oil, and sesame oil, are common adulterants of olive oil. Oils of

high specific gravity usually exhibit a dark colour; if the specific gravity of a pale oil exceeds 0.918, it should be looked upon as possibly adulterated with sesame, cottonseed or poppyseed oils. Admixture with rape oil tends to lower the specific gravity and the saponification value. Since olive oil has a lower iodine value than most other oils that might be used as adulterants, this figure constitutes a most reliable means of detecting adulteration. Some genuine oils, particularly those of Tunisian and Algerian origin, give a reaction with the test for sesame oil given in the British Pharmacopœia, but on longer standing the colour of the acid layer changes from red to greenish-black. Olive oil is sometimes prepared by refining oil obtained by solvent extraction processes and such oil is often used for technical purposes.

Olive oil **contains** the glyceride of oleic acid, which constitutes about 90 per cent. of the portion remaining liquid when the oil is cooled to low temperatures; the remainder of the liquid portion consists largely of the glyceride of linolic acid. The part which congeals on cooling consists largely of the glyceride of palmitic acid and a very small proportion of the glyceride of arachidic acid. Phytosterol and free fatty acid are also usually present in small quantity in the oil, the proportion of free acid being considerable in the case of inferior, old or rancid oil.

Slightly **soluble** in alcohol (90 per cent.); miscible with ether, chloroform and light petroleum.

Standard, B.P.—Olive oil has a specific gravity of 0.915 to 0.918. Refractive index at 40°, 1.4605 to 1.4635. Acid value, not more than 2.0. Saponification value, 190 to 195. Iodine value, 79 to 88. It complies with tests for absence of cottonseed oil, of sesame oil, and of arachis oil. In making liniments, ointments, or plasters of the British Pharmacopœia, and of the British Pharmaceutical Codex, olive oil having an acid value not exceeding 6.0, but otherwise conforming to the above standard, may be used.

Action and Uses.—Olive oil is nutritious, demulcent and, owing to its lubricating action on the bowels, mildly laxative. As a laxative, 4 to 8 fluid ounces or more of olive oil is taken daily. It is administered in order to inhibit the secretion of gastric juice in the treatment of gastric and duodenal ulcers. Olive oil may be **administered** alone or in capsules, or in the form of emulsion. Large quantities of the oil (5 to 20 fluid ounces) are injected per rectum in constipation and to remove impacted fæces, and it is employed as a vehicle for the rectal administration of ether and paraldehyde. Olive oil may be **sterilised** by heating for one hour at 150°; it is used as a vehicle for the hypodermic administration of camphor, ether, etc. It is injected hypodermically as a nutrient in doses of 4 to 8 millilitres (1 to 2 fluid drachms). Externally, olive oil is emollient and soothing to inflamed surfaces; it may be applied freely to burns, alone or mixed with an equal quantity of lime water. It is applied to the skin to remove incrustations in eczema and psoriasis, and is used as a lubricant in massage. Olive oil is largely employed in pharmacy in the preparation of liniments, ointments and plasters. *Arachis*

oil or sesame oil may be used instead of olive oil in making liniments, plasters, ointments and soaps in India and in the African, Australasian, Eastern and Northern American divisions of the Empire.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Preparations

Emulsio Olei Olivæ, B.P.C.—(Emuls. Ol. Oliv.)—Emulsion of Olive Oil. It contains 50 per cent. v/v of olive oil. Dose.— 8 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Extractum Malti cum Oleo Olivæ, B.P.C.—(Ext. Malt. c. Ol. Oliv.)—Extract of Malt with Olive Oil. Olive oil, approximately 15 per cent. v/v, with extract of malt. Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Linimentum Calcii Hydroxidi, B.P.C.—(Lin. Calc. Hydrox.)—Liniment of Calcium Hydroxide. *Syn.*—Linimentum Calcis; Liniment of Lime. Solution of calcium hydroxide and olive oil, equal parts.

This liniment was included in the British Pharmacopœia, 1914, under the name of Linimentum Calcis.

Unguentum Aquosum, B.P.—(Ung. Aquos.)—Hydrous Ointment. Distilled water, about 25 per cent., and borax, 1 per cent., in white beeswax, white soft paraffin and olive oil.

OLEUM PALMÆ

(Ol. Palm.)

Palm Oil

Palm oil is a fat obtained from the fleshy portion of the ripe fruits of the palm tree, *Elæis guineensis* Jacq. which grows in immense numbers along the West Coast of Africa. The extraction is carried out by the natives, very crude methods being employed. The best qualities are obtained by allowing the fruits to ferment and then pressing or draining out the oil, while inferior qualities are prepared by boiling the pressed mass with water and skimming off the oil as it rises to the surface. Palm oil occurs as an orange-yellow to dark red fat, varying considerably in consistence and possessing a slightly sweetish taste and an odour resembling that of violets. The oil as imported always contains a large proportion of free fatty acids, sometimes as much as 50 per cent., or even more. Except in the case of the darker coloured varieties, it may be readily bleached, either by exposure to air, or by oxidising agents such as hydrogen peroxide, ozone, or potassium dichromate in acid solution, but it is not readily deodorised. It melts between 25° and 50°. The oil consists almost entirely of palmitin and olein, with small quantities of stearin and linolein. The colouring matter is carotene.

Soluble in light petroleum, ether and chloroform. The solubility in alcohol depends on the proportion of free fatty acid present.

Standard.—Palm oil has a refractive index at 40° of 1.451 to 1.459. Saponification value, 197 to 202. Iodine value, 49 to 57.

Uses.—Palm oil is used in large quantities in the manufacture of soap.

OLEUM PERSICÆ

(Ol. Persic.)

Persic Oil

Persic oil is the oil expressed from the seeds of *Prunus Persica* Stokes (peach kernel oil), or from the seeds of *Prunus Armeniaca* Linn. (apricot kernel oil). The oil closely resembles almond oil in its general characters. With the nitric acid test of the British Pharmacopœia, as described under *Oleum Amygdalæ*, peach kernel oil assumes a pale pink colour after standing for thirty minutes, while apricot kernel oil, under similar conditions, shows a deep pink. The oil does not solidify above -15° . It consists largely of the glycerides of oleic acid.

Soluble in light petroleum, ether and chloroform; slightly soluble in alcohol.

Standard.—Persic oil has a specific gravity of 0.917 to 0.921. Refractive index at 40° , 1.464 to 1.465. Acid value, not more than 8. Saponification value, 189 to 193. Iodine value, 100 to 110.

Uses.—Persic oil is used as a substitute for almond oil in the manufacture of toilet preparations. It may be sterilised by heating at 150° for one hour.

OLEUM PETROSELINI

(Ol. Petrosel.)

Oil of Parsley

Synonyms—Parsley Oil; Parsley Fruit Oil.

Oil of parsley is obtained by distillation from the fruit of parsley, *Carum Petroselinum* Benth. et Hook., cultivated in nearly all temperate climates. It occurs as a colourless or yellowish, thick liquid, having an odour different from that of the herb. The oil **contains** apiolc, $C_{12}H_{14}O_4$, which separates in crystals on cooling the oil to a low temperature. The oil obtained from German fruit contains this body in considerable quantity, and is sometimes semi-solid at ordinary temperatures; that obtained from French fruit is not so rich in apiolc. The terpene fraction of the oil boils at 160° to 164° , has a specific gravity of about 0.865 and a rotation of -30.8° ; *l*-pinene is therefore probably a constituent of the oil.

Standard.—Oil of parsley is soluble in 8 times its volume of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640). Specific gravity, 1.040 to 1.100. Optical rotation, -5° to -11° . Refractive index at 20° , 1.510 to 1.519.

Action and Uses.—Oil of parsley has properties similar to those of apiol (see Apiol).

Dose.—0.2 to 0.3 millilitre (3 to 5 minims).

OLEUM PICIS

(Ol. Pic.)

Oil of Tar

Oil of tar is obtained by the distillation of the dehydrated tar obtained by the destructive distillation of the woods of various species of *Pinus*. It consists of the whole of the volatile products of the tar freed from the pitch. It is a fairly mobile liquid, dark brownish-red in colour, with a characteristic, penetrating and rather unpleasant empyreumatic odour and a specific gravity greater than 1. Water shaken with it acquires a reddish-brown colour and an acid reaction, and on the addition of dilute ferric chloride solution a red colour is produced. On redistillation, oil of tar is separated into two fractions, the cut being made at the first appearance of an empyreumatic odour in the distillate. The first fraction, which varies in amount from different oils of tar, consists of a mobile, colourless or light yellow oil, tending to darken on keeping, with a specific gravity of about 0.87 and a refractive index of about 1.480. It is characterised by a pleasant, terpene-like odour and is known as "Light Oil of Tar" or **Spirit of Tar** and chiefly consists of hydrocarbons. Water shaken with it is almost neutral in reaction and, on the addition of dilute ferric chloride solution, no colour is produced. The second fraction consists of the whole of the remaining volatile products and, on redistillation, yields **Rectified Oil of Tar**, which is a light yellow oil, tending to darken on keeping, and possessing an empyreumatic odour similar to that of oil of tar. It consists of hydrocarbons and contains the whole of the phenols present in the original tar. Water shaken with it yields the same reactions as given above for oil of tar.

Action and Uses.—Oil of tar and spirit of tar are used for veterinary purposes. Rectified oil of tar is a powerful deodoriser, antiseptic and parasiticide. It is occasionally given internally as an anthelmintic and intestinal antiseptic and is also employed as an inhalation with hot water for chronic catarrhal affections. Externally, it is used as an antiseptic and stimulant in the treatment of eczema and similar skin diseases. Rectified oil of tar is best **administered** with glycerin and syrup, especially when given as a pulmonary antiseptic in phthisis and for coughs. Coster's Paste (Pigmentum Olei Picis cum Iodo) is used as an application for ringworm.

Dose.—0.06 to 0.3 millilitre (1 to 5 minims).

Preparation

Pigmentum Olei Picis cum Iodo, B.P.C.—(Pig. Ol. Pic. c. Iod.)—Oil of Tar and Iodine Paint. *Syn.*—Pigmentum Picis cum Iodo; Pasta Iodi et Picis; Coster's Paste. Iodine, about 20 per cent. w/v, in rectified oil of tar.

OLEUM PIMENTÆ

(Ol. Piment.)

Oil of Pimento

Oil of pimento, or allspice oil, is obtained by distillation from the dried, full-grown, unripe fruit of *Pimenta officinalis* Lindl. It occurs as a yellow or yellowish-red liquid, becoming gradually darker on keeping, and having the characteristic odour of the fruit and a pungent, spicy taste. An alcoholic solution gives with very dilute solution of ferric chloride a fine indigo-blue colouration. On shaking the oil with an equal volume of strong solution of ammonia, it is converted into a semi-solid mass. The oil contains eugenol, $C_{10}H_{12}O_2$, and a sesquiterpene, the exact nature of which has not yet been ascertained. The clove-like odour of the oil is doubtless due to the eugenol, but the characteristic odour is due to some other substance or substances as yet unknown. A certain amount of resin is also present, but the oil has not been fully investigated.

Soluble in all proportions of alcohol (90 per cent.); soluble in alcohol (70 per cent.) (1 in 3), forming a clear solution.

Standard.—Oil of pimento, determined by the method of the British Pharmacopœia for eugenol in Oleum Caryophylli, contains not less than 60 per cent. v/v of eugenol. Specific gravity, 1.035 to 1.057. Optical rotation, 0° to -5° . Refractive index at 20° , 1.500 to 1.536.

Action and Uses.—Oil of pimento is used as a carminative and as an adjuvant to aperient medicines. It is administered on sugar or as pimento water.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

OLEUM PINI PUMILIONIS

(Ol. Pini Pumil.)

Oil of Pumilio Pine

Oil of pumilio pine is obtained by distillation from the fresh leaves of *Pinus Pumilio* Hænke, growing chiefly in the Austrian Alps, more especially in the Tyrol. It occurs as a colourless or faintly yellowish liquid, having a pleasant, aromatic odour and a pungent taste. The oil formerly known as Oleum Pini Sylvestris is not now distilled from the fresh leaves of *Pinus sylvestris* Linn.; the oil sold under this name is the distillate from the leaves and twigs of various conifers, collected indiscriminately. Oil of pumilio pine contains *l*-pinene, *l*-phellandrene, sylvestrene, dipentene, cadinene, and up to 10 per cent. of bornyl acetate.

Soluble in alcohol (1 in 8).

Standard.—Oil of pumilio pine, determined by the method of the British Pharmacopœia for esters in volatile oils, contains not less than 4 per cent. w/w of esters, calculated as bornyl acetate, $C_{15}H_{20}O_2$. Specific

gravity, 0.865 to 0.873. Optical rotation, -6° to -15° . Refractive index at 20° , 1.470 to 1.480.

Action and Uses.—Oil of pumilio pine is an antiseptic and expectorant in chronic laryngitis and bronchitis, but is employed principally as an inhalation with hot water (Vapor Olei Pini, 1 part of oil in 40 parts of water diffused with light magnesium carbonate, 1 in 80), or in a spray with light liquid paraffin, for its stimulating and antiseptic action in catarrh of the respiratory passages. Externally, the oil is rubefacient and mildly counter-irritant and is used to rub over chronic rheumatic joints which are then covered with cotton-wool, or 1 fluid drachm may be added to a warm bath. The oil is **administered** on sugar, in capsules, in glycerin and syrup, or in the form of pastilles.

Dose.—0.06 to 0.3 millilitre (1 to 5 minims).

Preparations

Elixir Diamorphinae et Pini Compositum, B.P.C.—(Elix. Diamorph. et Pini Co.)—Compound Elixir of Diamorphine and Pine. Each fluid drachm contains approximately $\frac{3}{16}$ grain of diamorphine hydrochloride and $\frac{3}{8}$ grain of terpin hydrate with oil of pumilio pine, alcohol (90 per cent.), compound solution of tartrazine, glycerin and sucrose. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Pastilli Diamorphinae et Pini Compositus, B.P.C.—(Pastill. Diamorph. et Pini Co.)—Compound Diamorphine and Pine Pastilles. Each pastille contains $\frac{3}{16}$ grain of diamorphine hydrochloride, $\frac{1}{2}$ minim of oil of pumilio pine and $\frac{1}{8}$ grain of terpin hydrate.

Syrupus Pini, B.P.C.—(Syr. Pini)—Syrup of Pine. Oil of pumilio pine, 1 in 160, with alcohol (90 per cent.), compound solution of tartrazine, glycerin, sucrose and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

OLEUM PULEGII

(Ol. Puleg.)

Oil of Pulegium

Synonym—Oil of Pennyroyal.

Oil of pulegium is obtained by distillation from fresh pennyroyal herb, *Mentha Pulegium* Linn. It occurs as a yellow or greenish yellow liquid, having a strong, aromatic, mint-like odour and an aromatic taste. The chief constituent of the oil is the ketone, pulegone, $C_{10}H_{16}O$, which is a colourless liquid, gradually becoming pale yellow and having a peppermint-like odour; its specific gravity is about 0.936; boiling-point, 221° ; optical rotation, $+22.9^{\circ}$; refractive index, 1.481 to 1.4865.

Standard.—Oil of pulegium contains not less than 85 per cent. v/v of pulegone. Specific gravity, 0.930 to 0.960. Optical rotation, $+14^{\circ}$ to $+28^{\circ}$. Refractive index at 20° , 1.475 to 1.490. It is soluble in 3 times its volume of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Assay.—Introduce 5 millilitres of the oil into an absorption flask with a graduated neck, as used for phenol determinations. Add 75

millilitres of 40 per cent. w/v sodium sulphite solution and sufficient solution of phenolphthalein to give a well-marked pink colouration. Shake vigorously, and neutralise with acetic acid diluted with twice its volume of distilled water, added in successive portions as the reaction proceeds. Heat on a water-bath, adding acetic acid as required to neutralise the liberated alkali, and shaking frequently during at least four hours. When the reaction is complete, fill up the flask with sodium sulphite solution, allow to stand overnight and measure the unabsorbed oil which has separated. Deduct the volume of unabsorbed oil from 5 millilitres and multiply by 20.

Action and Uses.—Oil of pulegium is employed chiefly as an emmenagogue. During excretion it mildly irritates the kidneys and bladder and reflexly excites uterine contractions. The oil is **administered** on sugar, or with a draught of water.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

Preparation

Spiritus Pulegii, B.P.C.—(Sp. Puleg.)—Spirit of Pulegium. *Syn.*—Essence of Pennyroyal; *Essentia Pulegii*; Essence of Pulegium. Oil of pulegium, 1 in 10, in alcohol (90 per cent.). **Dose.**—0·6 to 1·2 millilitres (10 to 20 minims).

OLEUM RAPÆ

(Ol. Rap.)

Rape Oil

Synonym—Colza Oil.

Rape oil is the refined oil expressed from the seeds of *Brassica campestris* Linn. and certain other species of *Brassica*, which are extensively cultivated in Europe and Eastern India. The seeds contain approximately 40 per cent. of oil. Rape oil is a pale yellow, somewhat viscous oil, with a characteristic odour and, except in the most highly refined varieties, an unpleasant taste. Ravison oil is prepared from the seeds of a wild variety of *B. campestris* from the Black Sea district. It closely resembles rape oil, but usually has a higher iodine value and specific gravity, and contains more unsaponifiable matter. Rape oil and the other oils of the same group are distinguished from other vegetable oils by their higher viscosity, low saponification value and the large proportion of glycerides of erucic acid which they contain.

Standard.—Rape oil has a specific gravity of 0·913 to 0·917. Refractive index at 40°, 1·463 to 1·467. Acid value, not more than 5. Saponification value, 171 to 177. Iodine value, 97 to 105. Unsaponifiable matter, 0·6 to 1·2 per cent.

Action and Uses.—Rape oil is seldom given internally; it is, however, used in India as an edible oil. Externally, it is sometimes employed in place of olive oil. Rape oil is largely used as a lubricant and for burning.

OLEUM RICINI

(Ol. Ricin.)

Castor Oil

Castor oil is a fixed oil obtained by expression from castor oil seed. The expression is largely carried out in Italy, Marseilles, London and Hull, and the oil thus obtained is usually bleached by exposure to the sun or by chemical means. It occurs as a nearly colourless or pale yellow, viscid liquid, having a faint odour and a taste which is bland at first, but afterwards acrid and nauseating. When 1 millilitre of the oil is shaken with 0.5 millilitre of light petroleum (boiling-point, 50° to 60°), a clear solution is produced which becomes cloudy on the addition of a further 1.5 millilitres of the light petroleum. It forms a clear solution with an equal volume of dehydrated alcohol. On cooling the oil to 0° it remains bright, but on cooling to about -18° it congeals to a yellowish mass. The most distinctive features of the oil are its high specific gravity, the behaviour with dehydrated alcohol and with light petroleum, its high acetyl value and its high viscosity. The specific gravity is the highest of any natural fatty oil. Castor oil **contains** the glycerides of ricinoleic and *isoricinoleic* acids; the glycerides of stearic and dihydroxystearic acid are also present in small quantities. Ricinoleic acid, $C_{18}H_{33}O_3$, is a viscid liquid and yields when acted upon by nitrous acid a crystalline body, ricinelaidic acid; a similar reaction occurs when castor oil is treated with nitrous acid.

Soluble in alcohol (90 per cent.) (1 in 3.5); miscible with dehydrated alcohol, ether and glacial acetic acid.

Standard, B.P.—Castor oil has a specific gravity of 0.958 to 0.969. Refractive index at 40° , 1.4695 to 1.4730. Acid value, not more than 4.0. Saponification value, 177 to 187. Iodine value, 82 to 90. Optical rotation, not less than $+3.5^{\circ}$. It remains bright when maintained at 0° for three hours.

Action and Uses.—Castor oil is a mild purgative, its action being exerted as a result of saponification in the small intestine with formation of alkali ricinoleate. The oil is a valuable laxative and is particularly useful in acute diarrhoea, especially when due to any form of food poisoning; sometimes 0.6 millilitre (10 minims) of tincture of opium is added. Small repeated doses of 0.3 to 0.6 millilitre (5 to 10 minims) may be given in the intestinal colic of children. The oil is used as a rectal injection to remove impacted faeces, sometimes with olive oil. Externally, castor oil is sometimes applied, generally mixed with other emollients, for bed sores. The oil is often used as an ingredient of spirituous hair lotions. It is a soothing application when dropped into the eye after removal of foreign bodies, and is an excellent solvent for alkaloids, such as cocaine and atropine, when used in ophthalmic surgery. Castor oil is best **administered** in milk or lemon juice, in capsules, or as *Mistura Olei Ricini*. The dose should be administered an hour before breakfast, on an empty stomach. *Oleum Ricini Aromaticum* is

an agreeable form for administration to children. Castor oil may be sterilised by heating at 150° for one hour.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

MAGNESII RICINOLEAS.—Magnesium ricinoleate occurs as a white powder insoluble in water. It is used as a solid form of castor oil for the preparation of powders or pills. **Dose.**— 4 to 16 grammes (1 to 4 drachms).

SODII RICINOLEAS.—Sodium ricinoleate is the sodium salt of ricinoleic acid. Aqueous solutions have a low surface tension and have the power of detoxicating bacterial toxins. It has been used as an antiseptic in dentistry, either in solution or mixed with soft paraffin. It has also been administered internally in enteric-coated capsules in the treatment of anaphylactic reactions.

Preparations

Emulsio Olei Ricini Aromatici, B.P.C.—(Emuls. Ol. Ricin. Aromat.)—Emulsion of Aromatic Castor Oil. It contains 30 per cent. v/v of aromatic castor oil. **Dose.**— 30 to 60 millilitres (1 to 2 fluid ounces).

Mistura Olei Ricini, B.P.C.—(Mist. Ol. Ricin.)—Castor Oil Mixture. Each fluid ounce contains 3 fluid drachms of castor oil emulsified with acacia in triple orange-flower water and cinnamon water. **Dose** (as a single draught).— 30 to 60 millilitres (1 to 2 fluid ounces).

This mixture was included in the British Pharmacopœia, 1914.

Oleum Ricini Aromaticum, B.P.C.—(Ol. Ricin. Aromat.)—Aromatic Castor Oil. Castor oil, flavoured with saccharin, vanillin, chloroform and oils of cinnamon, clove and pimento. **Dose.**— 4 to 30 millilitres (1 to 8 fluid drachms).

Unguentum Zinci et Olei Ricini, B.P.C.—(Ung. Zinc. et Ol. Ricin.)—Zinc and Castor Oil Ointment. Zinc oxide and castor oil in benzoinated lard. It is of the same composition as a mixture of equal weights of castor oil and the zinc ointment of the British Pharmacopœia, 1914.

Unguentum Zinci et Olei Ricini cum Benzoino, B.P.C.—(Ung. Zinc. et Ol. Ricin. c. Benzoin.)—Zinc and Castor Oil Ointment with Benzoin. Zinc oxide, castor oil and compound tincture of benzoin with benzoinated lard. The proportions of zinc oxide and benzoinated lard are equivalent to about 40 per cent. of the zinc ointment of the British Pharmacopœia, 1914.

OLEUM ROSÆ

(Ol. Ros.)

Oil of Rose

Synonym—Otto of Rose.

Oil of rose is obtained by distillation from the fresh flowers of the damask rose, *Rosa damascena* Linn., a plant which is cultivated largely in Bulgaria. It occurs as a pale yellow, semi-solid, crystalline mass at ordinary temperatures, having the strong, fragrant odour of the damask rose and a mild, slightly sweet taste. It yields turbid mixtures with even very large amounts of alcohol on account of the sparingly soluble paraffins; the liquid portion of the oil forms clear solutions with alcohol (70 per cent.). French oil of rose is distilled from the flowers of *Rosa centifolia* and other species, the product differing in odour and characters

from the Bulgarian oil. The chief adulterants of oil of rose are geraniol, citronellol and phenylethyl alcohol, all of which lower the melting-point and raise the specific gravity. Paraffin wax, spermaceti and alcohol are sometimes added to compensate for the above additions, and to raise the melting-point. An examination of the stearoptene is, therefore, necessary, after separation by means of alcohol or acetone. The great similarity of oil of rose to many of its adulterants renders detection by physical properties a matter of the greatest difficulty; the sense of smell is one of the most useful means of assessing the value of the oil. Oil of rose **contains** the alcohols, geraniol, $C_{10}H_{18}O$, and citronellol, $C_{10}H_{20}O$, the two together being present to the extent of from 70 to 75 per cent., while the citronellol constitutes about one-third to one-half of the liquid portion of the oil. Traces of esters of these alcohols are also present, but as the characteristic odour of the oil is not due to any of these constituents, either singly or mixed, the presence of some other odorous principle is assumed. The differences in the odour of varieties of the oil appear to indicate chemical differences. Free acids, from decomposition of the esters, are also present. The solid stearoptene is a mixture of two or more odourless paraffin hydrocarbons, melting at 33° to 37° .

Standard.—Oil of rose, when tested by the method of the British Pharmacopœia for Oleum Anisi, congeals at 18° to 22° and melts between 19° and 23° . Specific gravity ($30^{\circ}/15.5^{\circ}$), 0.852 to 0.862. Optical rotation, -2° to -4° . Refractive index at 25° , 1.458 to 1.465.

Uses.—Oil of rose is largely employed in perfumery. It is also used in lozenges, dentifrices, ointments and toilet preparations.

Preparations

Aqua Mellis, B.P.C.—(Aq. Mel.)—Honey Water. Oils of bergamot, lavender, clove and sandal wood, musk and saffron, with triple rose water, triple orange-flower water, honey and alcohol (90 per cent.).

Aqua Rosæ, B.P.C.—(Aq. Ros.)—Rose Water. Triple rose water diluted, immediately before use, with twice its volume of distilled water.

This water was included in the British Pharmacopœia, 1914.

Aqua Rosæ Concentrata, B.P.C.—(Aq. Ros. Conc.)—Concentrated Rose Water. Oil of rose, 1 in 100. One part added to 39 parts of distilled water yields a preparation which is approximately equivalent in strength to rose water, but contains 1.25 per cent. of alcohol (90 per cent.).

Aqua Rosæ Triplex, B.P.C.—(Aq. Ros. Trip.)—Triple Rose Water. The undiluted rose water of commerce.

Liquor Rosæ Dulcis, B.P.C.—(Liq. Ros. Dulc.)—Sweet Solution of Rose. Cochineal, 1 in 25, with oil of rose, potassium carbonate, potassium acid tartrate, potash alum, glycerin, alcohol (90 per cent.) and distilled water.

Unguentum Aquæ Rosæ, B.P.C.—(Ung. Aq. Ros.)—Rose Water Ointment. It contains rose water, white beeswax, borax, almond oil and oil of rose.

This ointment was included in the British Pharmacopœia, 1914.

Unguentum Rosæ Album, B.P.C.—(Ung. Ros. Alb.)—White Rose Ointment. *Syn.*—Ceratium Galeni. Triple rose water, 25 per cent., with white beeswax, spermaceti, oil of rose and almond oil.

OLEUM ROSMARINI

(Ol. Rosmarin.)

Oil of Rosemary

Oil of rosemary is obtained by distillation from the flowering tops of rosemary, *Rosmarinus officinalis* Linn., an evergreen shrub indigenous to Southern Europe and growing abundantly on dry, rocky hills in the Mediterranean regions. Most of the oil is imported from the South of France and the Dalmatian Islands, but that distilled in Britain is superior to the imported oil. It occurs as a colourless or pale yellow liquid, with a characteristic, pungent odour and a warm, bitter, camphoraceous taste. The chief adulterant is oil of camphor, which may be detected by the limit test for cineole. Oil of rosemary **contains** borneol, from 8 to 16 per cent., bornyl acetate and other esters, about 2 to 5 per cent., together with camphor, cineole, pinene and camphene. It should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of rosemary contains not less than 2 per cent. w/w of esters, calculated as bornyl acetate, $C_{12}H_{20}O_2$, and not less than 9 per cent. w/w of free alcohols, calculated as borneol, $C_{10}H_{18}O$. Specific gravity, 0.900 to 0.919. Optical rotation, -5° to $+10^\circ$. Refractive index at 20° , 1.464 to 1.476. It is soluble in an equal volume of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340), and in 10 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640). It complies also with a limit test for cineole.

Action and Uses.—Oil of rosemary has carminative properties. It is employed principally as Spiritus Rosmarini in hair lotions for its odour and for its supposed effect in stimulating the growth of the hair.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

Preparation

Spiritus Rosmarini, B.P.C.—(Sp. Rosmarin.)—Spirit of Rosemary. Oil of rosemary, 1 in 10, in alcohol (90 per cent.). Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

This spirit was included in the British Pharmacopæia, 1914.

OLEUM RUSCI

(Ol. Rusc.)

Birch Tar Oil

Synonyms—Oleum Betulæ Albæ; Oil of White Birch; Oleum Betulæ Pyroligneum.

Birch tar oil is prepared by the destructive distillation of the wood and bark of *Betula alba* Linn. The tar obtained is allowed to stand and separate into two layers, a tar, and an oil which constitutes birch tar oil.

It occurs as a thick liquid, brownish-black in colour and having a peculiar, agreeable, penetrating odour. The oil does not harden on exposure to the air. Russian leather owes its characteristic odour to the use of the oil in its preparation. A few drops of birch tar oil shaken with water and filtered, gives a solution which produces a pink colouration with potassium cyanide solution, intensified on the addition of ammonia. The aqueous solution, obtained by shaking 1 part with 10 parts of water, is almost colourless and has an acid reaction. With this solution a trace of ferric chloride produces a green colour. Birch tar oil contains, amongst other constituents, guaiacol, cresols and catechol. A rectified birch tar oil is obtained from the crude tar by steam distillation, having a specific gravity between 0.920 and 0.945; it is a light brown oil, differing in odour and composition from *Oleum Rusci*.

Soluble in oils, fats and chloroform; partially soluble in alcohol.

Standard.—Birch tar oil has a specific gravity of 0.920 to 0.955. Unsaponifiable matter, not less than 70 per cent. 5 millilitres of the aqueous solution, with 2 or 3 drops of aniline and about 5 drops of hydrochloric acid, produces a yellowish-brown but not a red colouration. A solution in light petroleum (1 in 20), on being shaken with a weak solution (about 1 in 1000) of copper acetate, does not assume a greenish colour (absence of fir tar).

Action and Uses.—Birch tar oil resembles oil of cade in its properties and is used for external application in the form of ointment (10 per cent.) or soap (10 per cent.) for eczema, psoriasis, and other skin affections. Mixed with essential oils it is used as a mosquito repellant.

OLEUM FAGI PYROLIGNEUM.—Oil of beech tar is used mixed with plaster of paris as a deodorant dusting powder in cases of gangrene and for bed sores.

Preparation

Unguentum Rusci Compositum, B.P.C.—(Ung. Rusc. Co.)—Compound Birch Tar Ointment. Birch tar oil, 8 per cent., with resorcinol, zinc oxide and starch, in hydrous wool fat and white soft paraffin.

OLEUM RUTÆ

(*Ol. Rut.*)

Oil of Rue

Oil of rue is obtained by distillation from rue, *Ruta graveolens* Linn., a plant cultivated in countries of temperate climate. It occurs as a pale yellow liquid, having a characteristic, sharp, unpleasant odour, becoming pleasant on considerable dilution. Oil of rue **contains** about 90 per cent. of methylnonylketone, $C_{11}H_{22}O$, and traces of methylmethylantranilate. The value of the oil depends on the amount of methylnonylketone contained in it, and the solidifying point affords

some indication of the amount of ketone present. Algerian oil of rue, from *R. montana*, contains methylheptylketone which is liquid at 0°; this oil cannot replace the oil distilled from *R. graveolens*.

Standard.—Oil of rue, determined by the method of the British Pharmacopœia for Oleum Anisi, has a freezing-point of 8° to 10° and a melting-point of 9° to 11°. Specific gravity, 0.832 to 0.845. Optical rotation, 0° to +3°. Refractive index at 20°, 1.430 to 1.440. It is soluble in three volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901), showing a blue fluorescence on further dilution.

Action and Uses.—Oil of rue has been employed as an antispasmodic in hysterical conditions and as an emmenagogue in amenorrhœa. It may be **administered** on sugar or in hot water. The oil is sometimes given as an enema, alone or with mucilage of starch or extract of ox bile, in post-operative intestinal stasis.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

OLEUM SABINÆ

(Ol. Sabin.)

Oil of Savin

Oil of savin is obtained from the fresh tops of *Juniperus Sabina* Linn. It occurs as a colourless or yellowish liquid, having a peculiar odour and a bitter, pungent camphoraceous taste. French oil of savin, derived from *Juniperus phœnicea* Linn., contains over 75 per cent. of pinene and only about 10 per cent. of sabinyl acetate. It has a lower specific gravity (about 0.890) and a lower optical rotation (+4° to +5°) than true oil of savin. The chief constituent of the oil is sabinol, $C_{10}H_{16}O$, occurring partly in the free state and partly combined as sabinyl acetate (about 35 to 55 per cent.). The sesquiterpene cadinene, $C_{15}H_{24}$, is present, and also some pinene.

Standard.—Oil of savin is soluble in from 1 to 2 volumes of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340). Specific gravity, 0.905 to 0.930. Optical rotation, +43° to +66°. Refractive index at 20°, 1.470 to 1.478. Acid value, 0.5 to 3.6. Saponification value, 101 to 169.

Action and Uses.—Oil of savin is a powerful irritant, both externally and internally. It is employed in amenorrhœa with other emmenagogues, but in addition to pelvic congestion it may cause hæmaturia and violent gastro-intestinal irritation, and its use, therefore, requires caution. It is usually **administered** in pills, the oil being massed with powdered liquorice and soap. In cases of **poisoning** by oil of savin, an emetic should be administered and castor oil given, with morphine hypodermically.

Dose.—0.06 to 0.24 millilitre (1 to 4 minims).

OLEUM SANTALI

(Ol. Santal.)

Oil of Sandal Wood*Synonym*—Oil of Santal Wood.

Oil of sandal wood is obtained by distillation from the heartwood of *Santalum album* Linn., a small tree indigenous to the mountains of India and cultivated in dry, open places in Southern India, chiefly in Mysore, Malabar and Coimbatore. It occurs as a pale yellow or nearly colourless, viscid liquid, with a peculiar, faint but persistent odour and an unpleasant, nauseous taste. Australian oil, other varieties of sandal wood oil and cedar wood oil have occurred as adulterants of the oil. Cedar wood oil increases the optical rotation, lowers the specific gravity and diminishes the solubility. West Indian sandal wood oil (so-called) is dextrorotatory and with difficulty soluble in alcohol (90 per cent.). Oil of sandal wood **contains** santalol, a mixture of two isomeric sesquiterpene alcohols of the formula $C_{15}H_{24}O$, which is present to the extent of over 90 per cent., and esters of santalol. The oil also contains an aldehyde, santalal, $C_{15}H_{22}O$, which yields santalenic acid on oxidation (melting-point, 76°). Oil of sandal wood should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (more than 1 in 1). The solubility diminishes under the action of air and light.

Standard, B.P.—Oil of sandal wood contains not less than 2 per cent. w/w of esters, calculated as santalyl acetate, $C_{17}H_{26}O_2$, and not less than 90 per cent. w/w of free alcohols, calculated as santalol, $C_{15}H_{24}O$. Specific gravity, 0.973 to 0.985. Optical rotation, -15° to -20° . Refractive index at 20° , 1.500 to 1.510. It is soluble at 20° in 5 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Action and Uses.—Oil of sandal wood is sometimes given in the sub-acute stages of cystitis and gonorrhœa for its action on the urinary passages during excretion; it is said to be of use in diminishing the frequency of micturition which is so marked in tuberculosis of the bladder. On account of its persistent taste, the oil is usually **administered** in capsules, often in combination with other volatile oils, or it may be given as an emulsion. Various compound solutions of oil of sandal wood with copaiba, cubeb, buchu, etc. are also prepared.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

Preparations

Liquor Copaibæ, Buchu et Cubebæ cum Oleo Santali, B.P.C.—(Liq. Copaib. Buchu et Cubeb. c. Ol. Santal.)—Solution of Copaiba, Buchu and Cubeb with Sandal Wood Oil. Oil of sandal wood, 1 in 10, and oil of cassia, 1 in 20, with solution of copaiba, buchu and cubeb, and alcohol (90 per cent.). Dose—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Copaibæ et Olei Santali, B.P.C.—(Liq. Copaib. et Ol. Santal.)—Solution of Copaiba and Sandal Wood Oil. Solution of copaiba, 4 in 5, with oils of sandal wood and cassia, and alcohol (90 per cent.). Dose—4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Santali Compositus, B.P.C.—(Liq. Santal. Co.)—Compound Solution of Sandal Wood Oil. Oil of sandal wood, 1 in 20, with oil of cinnamon, tincture of buchu, tincture of cubeb and alcohol (90 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

OLEUM SANTALI AUSTRALIENSIS

(Ol. Santal. Austral.)

Oil of Australian Sandal Wood

Oil of Australian sandal wood is obtained, by distillation and rectification, from the wood of *Eucarya spicata* Sprague and Summerhayes (*syn.*—*Santalum spicatum*), a large bush found in West Australia. It occurs as a colourless or pale yellow, oily liquid, with a characteristic odour and an unpleasant taste. Oil of Australian sandal wood **contains** alcohols which are isomeric with the santalols. It should be **stored** in well-closed containers in a cool place and protected from light.

Standard, B.P.—Oil of Australian sandal wood contains not less than 90 per cent. w/w of free alcohols, calculated as $C_{15}H_{24}O$. Specific gravity, 0.970 to 0.976. Optical rotation, -3° to -10° . Refractive index at 20° , 1.498 to 1.508. It is soluble at 20° in 3 to 6 volumes of alcohol (70 per cent.; specific gravity, 0.8896 to 0.8901).

Action and Uses.—Oil of Australian sandal wood has properties similar to those of sandal wood oil and is used for the same purposes. Oils of sandal wood are also used in perfumery.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

OLEUM SASSAFRAS

(Ol. Sassaf.)

Oil of Sassafras

Oil of sassafras is obtained by distillation from the root or the root bark of species of *Sassafras* T. Nees and Eberm. It occurs as a pale yellow or reddish-yellow liquid, having the characteristic odour of safrole and a warm, aromatic taste. The chief **constituent** of the oil is safrole, $C_{10}H_{10}O_2$, which is present to the extent of about 80 per cent. and is the body to which the oil owes its odour and chief properties. Most of the safrole may be separated from the oil by freezing. Artificial sassafras oil consists of fractions of camphor oil of a specific gravity approaching that of the genuine oil.

Standard.—Oil of sassafras is soluble in 3 volumes of alcohol (90 per cent.; specific gravity, 0.8334 to 0.8340), the solution being neutral to litmus. Specific gravity, 1.070 to 1.084. Refractive index at 20° , 1.523 to 1.531. Optical rotation, $+1^{\circ}$ to $+5^{\circ}$.

Action and Uses.—Oil of sassafras has rubefacient properties. It is seldom given internally; in large doses, the oil, like the oils of pulegium, thyme and rosemary, causes fatty changes in the liver. Externally, oil of sassafras is sometimes employed as an anodyne liniment in chronic rheumatism in the same manner as oil of camphor. It is used to destroy pediculi, but its use is not unattended with danger; the oil should be applied to the hair with a stiff brush, leaving the skin untouched.

Dose.— 0·06 to 0·3 millilitre (1 to 5 minims).

OLEUM SESAMI

(Ol. Sesam.)

Sesame Oil

Synonyms—Gingelly Oil; Teel Oil.

Sesame oil is the fixed oil obtained by expression from the seeds of *Sesamum indicum* Linn., a plant largely grown in India, China, Japan and other tropical countries. It occurs as a pale yellow, limpid liquid, with a slight, pleasant, grain-like odour and a bland taste. It does not solidify when cooled to 0°. Sesame oil may be identified, and its presence in other oils detected, by the following test, known as Baudouin's test.—Shake the oil with half its volume of a 1 per cent. w/v solution of sucrose in hydrochloric acid, and allow the mixture to stand for five minutes; the acid layer acquires a deep pink colour. The sugar may be replaced by one or two drops of a 2 per cent. w/v alcoholic solution of furfural. By the addition of a suitable colouring agent, a substituted oil could be prepared so as to give a pink colour on the addition of hydrochloric acid; the test should therefore be repeated on the sample without the addition of sucrose or furfural, when no colouration should be produced. The chromogenic substance passes completely into the fatty acids when these are separated, and is not destroyed by heating the oil to between 200° and 250° for twenty minutes. The common adulterants are arachis oil, cottonseed oil and rape oil. Sesame oil **contains** glycerides of oleic and linoleic acids, with small proportions of the glycerides of stearic, palmitic and myristic acids. Sesamin, $C_{18}H_{18}O_5$, another constituent of the oil, may be obtained in long, crystalline needles melting at 118°.

Slightly **soluble** in alcohol (90 per cent.); miscible with ether, chloroform and light petroleum.

Standard, B.P.—Sesame oil has a specific gravity of 0·921 to 0·924. Refractive index at 40°, 1·4650 to 1·4665. Acid value, not more than 4·0. Saponification value, 188 to 193. Iodine value, 103 to 112. It complies also with tests for the absence of cottonseed oil and of arachis oil.

Action and Uses.—Sesame oil has properties similar to those of olive oil, and may be used instead of olive oil in the preparation of

official liniments, plasters, ointments and soaps in India, and in the Eastern, African, Australasian and North American divisions of the Empire. It is used in the preparation of additive compounds of iodine and bromine, which are employed for external, internal or subcutaneous use, and as an opaque medium for the X-ray examination of a directly accessible cavity of the body. Sesame oil may be sterilised by heating at 150° for one hour. The best qualities of the oil are largely used in the manufacture of margarine.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

OLEUM SINAPIS EXPRESSUM

(*Ol. Sinap. Express.*)

Expressed Oil of Mustard

Synonym—Black Mustard Oil.

Expressed oil of mustard is obtained by pressure from the seed of *Brassica nigra* (Linn.) Koch. It is obtained as a by-product in the manufacture of the volatile oil, and occurs as a brownish-yellow or greenish-brown liquid, having a mild taste. It consists chiefly of the glyceride of oleic acid, and contains small amounts of glycerides of solid fatty acids, including arachidic. The oil does not solidify until the temperature falls to about -15°.

Slightly **soluble** in alcohol; miscible with ether, chloroform and light petroleum.

Standard.—Expressed oil of mustard has a specific gravity of 0.916 to 0.920. Refractive index at 40°, 1.4655 to 1.4670. Saponification value, 174 to 180. Iodine value, 115 to 126.

Action and Uses.—Expressed oil of mustard has mild rubefacient properties. It is employed as an application to the chest in place of camphorated oil, and as a liniment for rheumatic joints.

WHITE MUSTARD SEED OIL is obtained from the seed of *Brassica alba* Boiss., and occurs as a golden-yellow liquid, having a burning taste. Specific gravity, 0.912 to 0.917. Refractive index at 40°, 1.4650 to 1.4660. Saponification value, 171 to 178. Iodine value, 98 to 108. The oil obtained from white mustard seed is used for lubricating and also for burning.

OLEUM SINAPIS VOLATILE

(*Ol. Sinap. Vol.*)

Volatile Oil of Mustard

Volatile oil of mustard may be prepared synthetically, or obtained by distillation from the dried, ripe seeds of black mustard, *Brassica*

nigra (Linn.) Koch, after they have been deprived of fixed oil and macerated with tepid water (below 70°) for several hours, when a reaction takes place between the glycoside, sinigrin (potassium myronate), and the ferment, myrosin, with the production of mustard oil. The synthetic oil is obtained by the interaction of allyl iodide and potassium thiocyanate in alcoholic solution; allyl thiocyanate is first formed, and under the influence of heat is converted into allyl *isothiocyanate*. Volatile oil of mustard occurs as a colourless or pale yellow, strongly refractive, mobile liquid, having an intensely pungent odour and an acrid taste. Great caution should be taken in smelling the oil. In contact with the skin it causes almost immediate blistering. Exposed to light it gradually becomes reddish-brown, and at the same time deposits a film on the inside of the bottle. The specific gravity serves to indicate the absence of chloroform, carbon disulphide, fatty oils, alcohol and petroleum. Allyl *isothiocyanate* forms a solid, non-volatile compound with ammonia. On adding excess of ammonia and alcohol to volatile oil of mustard, the odour of both disappears gradually in the cold, but more quickly on heating, while crystals of thiosinamine are formed. Volatile oil of mustard **contains** allyl *isothiocyanate*, C_3H_5NCS , to which the high specific gravity of the oil is due. It also contains small and variable amounts of allyl cyanide, carbon disulphide, and probably traces of isomeric allyl thiocyanate.

Soluble in water (1 in 50), in alcohol (70 per cent.) (1 in 10), in all proportions of alcohol, ether, amyl alcohol, benzene, light petroleum and carbon disulphide.

Standard.—Volatile oil of mustard contains not less than 92 per cent. w/w of C_3H_5NCS . Specific gravity, 1·014 to 1·025. Refractive index at 20°, 1·525 to 1·530. Optically inactive. 1 millilitre of the oil diluted with 5 millilitres of alcohol produces no blue or bluish-green colour on the addition of a drop of ferric chloride solution (absence of phenols).

Assay.—Dissolve about 4 grammes, accurately weighed, in sufficient alcohol to produce 100 millilitres. To 5 millilitres of this solution in a 100 millilitre flask add 50 millilitres of N/10 silver nitrate and 5 millilitres of strong solution of ammonia; heat under a reflux condenser on a boiling water-bath for thirty minutes; cool to 15·5°, dilute to 100 millilitres with water, and filter. To 50 millilitres of the filtrate add 4 millilitres of nitric acid, and titrate the excess of silver nitrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate as indicator; each millilitre of N/10 silver nitrate is equivalent to 0·004955 gramme of C_3H_5NCS .

Action and Uses.—Volatile oil of mustard is an extremely powerful irritant, and when applied to the skin it produces vesication very rapidly. The very painful nature of blisters caused by mustard is explained by the volatility and consequently great penetrating power of the oil. Diluted with fifty times its volume of alcohol or Cologne spirit, or as Linimentum Sinapis, the oil is employed as a counter-irritant and rubefacient in

cases where blisters cannot readily be applied, especially to paint behind the ear in catarrh of the middle ear. It is also used in cases of pleurisy and pneumonia, and to relieve deep-seated pain.

Preparation

Linimentum Sinapis, B.P.C.—(Lin. Sinap.)—Liniment of Mustard. Volatile oil of mustard, about 1 in 30, with camphor and castor oil in alcohol (90 per cent.).

OLEUM SOJÆ

(Ol. Sojæ)

Soya Oil

Synonyms—Soya Bean Oil; Soy Bean Oil; Soya Bean Oil.

Soya oil is obtained by expression from the seeds of the soya plant, which is indigenous to China, Formosa, Indo-China, Japan, Korea and Manchuria. The yield of oil varies from 10 to 12 per cent. When heated to 260°, the oil becomes pale and remains so. It occurs as a pale-yellow to brownish-yellow oil, with a slight but characteristic taste and smell. The oil **contains** the glycerides of oleic and linolic acid with smaller proportions of the glycerides of palmitic, stearic and linolenic acids. In its general properties it is intermediate between linseed oil and cottonseed oil. It gives no characteristic colour reaction.

Slightly **soluble** in alcohol; miscible with ether, chloroform and light petroleum.

Standard.—Soya oil has a specific gravity of 0.924 to 0.927. Refractive index at 40°, 1.4675 to 1.4685. Acid value, not more than 5. Saponification value, 190 to 194. Iodine value, 130 to 137. Unsaponifiable matter, 0.7 to 1.5 per cent.

Action and Uses.—Soya oil is edible, and it may be used as a substitute for either linseed or cottonseed oil for soap-making purposes. It is also used as a lamp oil, and in varnishes, but for this purpose it is inferior to linseed oil. Like other vegetable oils, it does not contain the fat-soluble vitamins.

OLEUM SUCCINI

(Ol. Succin.)

Oil of Amber

Synonyms—Oleum Succini Rectificatum; Rectified Oil of Amber.

Oil of amber is obtained by the destructive distillation of resins, or as a distillate of resin oil. It was formerly obtained from amber by destructive distillation, and purified by redistillation. It occurs as a

transparent, pale yellow or brownish-yellow liquid, having a penetrating, disagreeable odour and a burning, acrid taste. It is a variable product; the specific gravity varies from 0.850 to 0.940.

Soluble in alcohol (90 per cent.), ether, chloroform and in fixed oils.

Action and Uses.—Oil of amber has properties resembling those of oil of turpentine, and is sometimes given internally in the treatment of asthma and whooping cough. It is best **administered** on sugar. Externally, mixed with olive oil or camphorated oil, or as Linimentum Succini Compositum, it is used to rub on rheumatic parts, and on the chest in cases of bronchitis and whooping cough.

Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

Preparation

Linimentum Succini Compositum, B.P.C.—(Lin. Succin. Co.)—Compound Liniment of Amber. Oil of amber and oil of clove, of each 1 in 4, in olive oil.

OLEUM TEREBINTHINÆ

(Ol. Terebinth.)

Oil of Turpentine

Synonyms—Oleum Terebinthinæ Rectificatum; Rectified Oil of Turpentine.

Oil of turpentine is the oil obtained by distillation and rectification from turpentine, an oleo-resin obtained from *Pinus palustris* Mill., *P. maritima* Lam. and other species of *Pinus* growing in America, France, Russia and elsewhere. The varieties of oil of turpentine usually found in commerce are the French and the American, most of the oil being imported from America. It occurs as a colourless, limpid liquid, with a strong, peculiar odour and a pungent, somewhat bitter taste, both becoming stronger and less pleasant on storage and on exposure to the air. The odour of the French oil is finer and milder than that of the American oil. The sharp odour is said to be due to an aldehyde formed by exposure of the oil to the air. French turpentine is always strongly lævorotatory, the American variety contains both lævo- and dextro-terpenes, and may be either lævo- or dextrorotatory. On exposure to the air the oil undergoes rapid change, especially in the presence of moisture. It becomes viscid and yellow, and acquires an acid reaction, the specific gravity increases, the boiling-point rises and, unlike most oils, the solubility in alcohol increases. These changes are all caused by slow oxidation. When treated with sulphuric acid oil of turpentine yields terebene, the pinene being converted into dipentene.

The common adulterants are petroleum, resin oil and wood turpentine. Petroleum may be detected by its lowering the specific gravity.

and also by the flash-point, which for pure oil of turpentine is from 33° to 34°. Resin oil, a product of the destructive distillation of colophony, may be detected by the fatty stain which the adulterated oil leaves when evaporated from paper. Wood turpentine, which is obtained by distilling the roots and stumps of various species of *Pinus*, has a lower iodine value and a higher specific gravity.

Oil of turpentine **contains** hydrocarbons, principally Δ -3-carene in the case of Indian, Russian and Scandinavian oils, and the isomeric bodies, *d*- and *l*-pinene, in American and French oils. Other constituents are resin acids, camphene and fenchene, while dipentene, the optically inactive form of limonene, and polymerised terpenes may occur as the result of the action on pinene of the acids present. Traces of oxidation products such as formic, acetic and camphoric acids, as well as camphoric aldehyde, $C_{10}H_{16}O_3$, are also present, the last-named giving the peculiar odour to old oil of turpentine. The action of direct sunlight in the presence of air and moisture causes the formation of pinol hydrate, $C_{10}H_{18}O_2$, while the continuous action of air and moisture develops a large quantity of oxygenated products, including hydrogen peroxide and camphoric acid. Oil of turpentine should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in alcohol (90 per cent.) (1 in 7); miscible with dehydrated alcohol, alcohol (95 per cent.), chloroform, ether, carbon disulphide and glacial acetic acid.

Standard, B.P.—Oil of turpentine has a specific gravity of 0.860 to 0.870. Refractive index at 20°, 1.467 to 1.477. Iodine value, determined by a specified method, not less than 340. Residue on rapid evaporation in a flat dish on a water-bath, not more than 0.5 per cent.

Action and Uses.—The action of oil of turpentine is representative of that of a large number of volatile oils. They are antiseptic, whether used internally or externally, and in sufficient concentration are rapidly germicidal to all forms of bacteria. Taken internally, the volatile oils excite a reflex flow of saliva, and cause a sensation of warmth in the mouth and stomach. They are carminative, relieve colic, and assist in the expulsion of flatus. They are absorbed unchanged into the blood, and produce leucocytosis, excretion taking place through the lungs, skin and kidneys. During excretion by the bronchioles they act as expectorants, assisting in the expulsion of mucus; excretion by the skin causes some diaphoresis and may give rise to mild skin eruptions, this being especially common with oil of copaiba. The most important action of many volatile oils is that exerted upon the genito-urinary tract after excretion by the kidneys. They produce dilatation of renal vessels and consequently diuresis, and appear in the urine in association with glycuronic acid. They lessen inflammatory exudation, and retard putrefaction of the urine. Large doses set up inflammation of the bladder and urethra, and small doses may exaggerate pre-existing inflammatory conditions; the oils are therefore given only in the sub-acute stages of disease. Applied to the skin the volatile oils produce

irritation and rubefaction, the redness being due to dilatation of the superficial vessels. Inhaled, they arrest profuse secretion and relieve congestion of the bronchioles, but the degree of concentration obtainable in this manner is insufficient for their antiseptic action to be exerted to any great extent.

Oil of turpentine is given in small doses in bronchitis and phthisis. Large doses are purgative and anthelmintic; to prevent absorption they are best given with castor oil. As an enema, with or without castor oil, it is used to expel tape-worms and thread-worms, and to evacuate the bowel and remove flatulent distension. It is given internally, and by enema with olive oil, in the tympanites of typhoid fever. Subcutaneous injection of oil of turpentine is employed to promote the formation of a "fixation abscess" in obscure infections, in order to assist in the isolation of the infecting organism. It should not be administered during pregnancy. Oil of turpentine is employed externally as a counter-irritant and rubefacient in the form of *Linimentum Terebinthinæ* or *Linimentum Terebinthinæ Aceticum* in the treatment of chronic rheumatism and various chest affections. To relieve deep-seated pain and inflammation, as in peritonitis, flannels are wrung out in hot water, sprinkled with oil of turpentine and applied to the seat of pain. The oil is used as an inhalation in chronic bronchitis, but terebene is usually preferred. It is used also to arrest minor hæmorrhage from the tooth socket or nose.

Oil of turpentine may be **administered** in mixture form, emulsified with half its weight of powdered acacia, or one-fourth its weight of powdered tragacanth; it is also given enclosed in gelatin capsules. It has been given as an antidote in cases of poisoning by phosphorus, but although it combines with the phosphorus to form compounds of a less toxic nature than that substance, the results have not been entirely satisfactory. In cases of **poisoning** by large doses of oil of turpentine, emetics and demulcent drinks should be given, with magnesium sulphate to promote purgation, and opium to relieve pain.

Dose.—0·2 to 0·6 millilitre (3 to 10 minims); as an anthelmintic, 8 to 16 millilitres (2 to 4 fluid drachms).

Preparations

Linimentum Album, B.P.C.—(Lin. Alb.)—White Liniment. *Syn.*—Egg Liniment; White Embrocation; *Linimentum Album Aceticum*. An egg emulsion containing acetic acid, about 1 in 12, and oil of turpentine, about 1 in 2½.

Linimentum Terebinthinæ, B.P.—(Lin. Terebinth.)—Liniment of Turpentine. Oil of turpentine, 65 per cent., v/v, and camphor, 5 per cent. w/v, emulsified in water by means of soft soap.

Linimentum Terebinthinæ Aceticum, B.P.—(Lin. Terebinth. Acet.)—Acetic Liniment of Turpentine. *Syn.*—Liniment of Turpentine and Acetic Acid. Glacial acetic acid, 11 per cent. v/v, and liniment of camphor, 44·5 per cent. v/v, in oil of turpentine.

Terebinthina Veneta Factitia, B.P.C.—(Tereb. Venet. Fact.)—Factitious Venice Turpentine. A mixture of colophony, linseed oil and oil of turpentine.

OLEUM THEOBROMATIS

(Ol. Theobrom.)

Oil of Theobroma*Synonyms*—Cocoa Butter; Cacao Butter.

Oil of theobroma is a solid fat obtained by expression from crushed and roasted theobroma seed and is obtained as a by-product in the manufacture of cocoa. It occurs as a yellowish-white or pale yellow solid, becoming white on keeping. It has a slight, agreeable odour resembling that of cocoa, and a bland taste. It is usually supplied in oblong cakes, brittle when cold, breaking with a smooth fracture which shows indications of crystalline structure, and becoming soft at 25°. The common adulterants are dika fat, illipe butter, paraffin, stearin, coconut stearin, wax, tallow or other fats. Oil of theobroma **contains** the glycerides of stearic (about 40 per cent.), palmitic and oleic acids, together with small quantities of the glycerides of arachidic, linoleic and other fatty acids.

Soluble in ether, chloroform, benzene, light petroleum and boiling dehydrated alcohol; slightly soluble in alcohol (90 per cent.).

Standard, B.P.—Oil of theobroma has a melting-point of 30° to 35°. Refractive index at 40°, 1·4565 to 1·4575. Acid value, not more than 4·0. Saponification value, 188 to 195. Iodine value, 35 to 40. It complies also with a test for the absence of wax, stearin and tallow.

Action and Uses.—Oil of theobroma is employed in pharmacy chiefly for the preparation of suppositories, pessaries and bougies. It is customary to prepare suppositories, etc., with an oil of theobroma basis, in the absence of any indication to the contrary. In hot climates, and for ingredients which lower the melting-point of the oil, it is sometimes advisable to add a small proportion of wax to the mass. Oil of theobroma is sometimes an ingredient of emollient ointments. An emulsion and ethereal solution of theobroma have been used as lubricants in the preparation of compressed tablets. The oil is also used as a lubricant in massage.

OLEUM THYMI

(Ol. Thym.)

Oil of Thyme

Oil of thyme is obtained by distillation from the leaves and flowering tops of *Thymus vulgaris* Linn. and other species of *Thymus*, indigenous to the countries bordering on the Mediterranean and now cultivated in most countries with a temperate climate. It occurs as a dark reddish-brown liquid, having a pleasant, strong, thyme odour and a biting, persistent taste, which is afterwards cooling. Spanish thyme oils are derived from species of *Origanum* which yield oils of similar composition.

Oil of thyme is also used under the name of oil of origanum, but the commercial oil of origanum is a mixture of oil of thyme and oil of turpentine. Oil of thyme **contains** about 45 per cent. of thymol and its isomeride, carvacrol. Other constituents are cymene, *l*-pinene, borneol, linalol and bornyl acetate.

Standard.—Oil of thyme, determined by the method of the British Pharmacopœia for eugenol in *Oleum Caryophylli*, contains not less than 40 per cent. v/v of phenols. Specific gravity, 0.905 to 0.960. Refractive index at 20°, 1.483 to 1.510. It is soluble in 2 volumes of alcohol (80 per cent.; specific gravity, 0.8634 to 0.8640).

Action and Uses.—Oil of thyme has antiseptic, antispasmodic and carminative properties, and is used in the treatment of whooping cough and bronchitis. Externally, it is employed in combination with olive oil and other oils as a rubefacient and counter-irritant in rheumatism, etc.

Dose.—0.06 to 0.3 millilitre (1 to 5 minims).

OLEUM MARJORANÆ.—Oil of marjoram is derived from *Origanum Marjorana* Linn. It consists principally of terpenes and is practically devoid of phenols. Specific gravity, 0.888 to 0.912; optical rotation, +13° to +20°.

OLEUM ORIGANI.—True origanum oil is derived from *Origanum hirtum* Link (Trieste) and *O. majoranoides* Willd. (Cyprus). The Cyprus oil is the better quality, containing 70 to 85 per cent. of carvacrol and having a specific gravity of 0.950 to 0.967. The Trieste oil may contain from 60 to 85 per cent. of carvacrol.

OLEUM THYMI ALBUM.—White oil of thyme is prepared by fractional distillation from oil of thyme. It has a lower specific gravity and contains from 20 to 30 per cent. of phenols.

OLIBANUM

(Oliban.)

Olibanum

Synonym—Frankincense.

Olibanum is the dried oleo-resinous secretion obtained from the bark of *Boswellia Carterii* Birdw. (Fam. Burseraceæ) and other species of *Boswellia*, small trees indigenous to Somaliland and Southern Arabia.

Olibanum occurs in small tears, from 5 to 25 millimetres in length, usually ovoid, and of a pale yellowish, bluish, or greenish colour. The surface is dusty, and dull after removal of the dust. Internally, it is dull, waxy and semi-translucent. In some softer samples the tears have become agglomerated into masses. The odour is agreeable and characteristically balsamic, and the taste is fragrant and slightly bitter, the tears easily breaking up and softening to a plastic mass on mastication.

Olibanum **contains** resin (60 to 70 per cent.) composed chiefly of a resin acid (boswellic acid) and a resene (olibanoresene) in about

equal proportions, gum (about 27 to 35 per cent.) consisting mainly of arabin with a little bassorin, and about 3 to 8 per cent. of a volatile oil. The volatile oil is colourless, pale yellow and fragrant, and varies in composition according to the method of preparation.

Uses.—Olibanum is used as an ingredient of incense and fumigating powders.

OLIVERI CORTEX

(*Oliver. Cort.*)

Oliver's Bark

Synonym—Black Sassafras.

Oliver's bark is the dried bark of *Cinnamomum Oliveri* Bailey (Fam. Lauraceæ), a tree indigenous to New South Wales and Queensland.

The bark occurs in flat pieces usually about 20 centimetres long, 4 centimetres wide and 1 centimetre thick. The outer surface is brownish, with patches of whitish cork, very coarsely granular or warty; the inner surface is amber-brown, finely striated, and satiny; the fracture is short and somewhat fibrous. The smoothed transverse section viewed under a lens shows a rhytidome of varying thickness, sometimes exhibiting alternating darker and paler lines of cells, and a thick, dark brown secondary phloem, containing numerous paler groups of stone cells and bast fibres. The odour is agreeable, recalling that of sassafras, and the taste is aromatic, slightly bitter and pungent.

Oliver's bark **contains** about 2·5 per cent. of a yellow volatile oil, which contains pinene, *d*-camphor, safrole and eugenolmethylether. The bark also contains tannin.

Action and Uses.—Oliver's bark is used in Australia as a substitute for cinnamon. It is **administered** in the form of a tincture (*Tinctura Oliveri Corticis*, 1 in 10 of alcohol (60 per cent.); dose, $\frac{1}{2}$ to 1 fluid drachm).

OPIUM

(*Opium*)

Opium

Opium consists of the partly dried latex obtained from the unripe capsules of *Papaver somniferum* Linn. (Fam. Papaveraceæ). It is collected principally in Yugoslavia, Greece, Bulgaria, Asiatic Turkey, Persia, India and China. The capsules contain an extensive system of laticiferous vessels from which the latex drains when the capsules are incised. The nature of the incisions varies in different countries; they may be single or in groups, vertical, transverse, or oblique, but do not penetrate to the interior of the capsule in order to avoid loss of latex

and deterioration of the seeds. In the Balkans and Asiatic Turkey, the incision takes the form of a transverse cut extending spirally around the capsule, and one incision is made; in India one vertical cut is made with a three or four-bladed knife, each capsule being usually lanced at intervals of three days until no more latex exudes. The exuded juice, partly dried, is collected by scraping, further dried in various ways, and eventually formed into cakes or bricks which are then wrapped in poppy leaves or paper.

The characters of the different varieties of opium differ somewhat widely (see under varieties).

Opium **contains** the alkaloid, morphine, which occurs in commercial varieties in proportions varying from 5 to 21 per cent. of the dried opium. Opium, of any variety, containing much less than 10 per cent. of morphine is usually adulterated. The morphine exists in combination with meconic and sulphuric acids in the form of salts readily soluble in water. The "Soft Shipping" variety of Turkey opium contains about 15 to 18 per cent. of morphine, while "Druggists'" opium of good quality contains about 12 to 16 per cent., both calculated on the dried drug. Dried European opium contains from about 15 to 21 per cent. of morphine, or occasionally even more. Persian opium of good quality contains about 10 to 12 per cent., and occasionally as much as 13.5 per cent. of morphine. Undried Indian medicinal opium has varied considerably at different times, sometimes containing as little as 7 per cent., and sometimes as much as 12 per cent., while Indian smoking opium contains only from 4 to 6.5 per cent. of morphine. The proportion of narcotine, which exists partly in the free state and partly as a salt, ranges from 1.5 to 12.5 per cent., usually being from 2 to 7 per cent. Codeine is present to the extent of 0.3 to 4 per cent. in combination with acids, Indian opium containing the highest proportion and Turkey opium the lowest. The remaining alkaloids constitute about 1 per cent. of the drug. They include thebaine, narceine, papaverine, meconidine, codamine, laudanine, laudanosine, neopine, lanthopine, protopine, cryptopine, rhœadine, oxynarcotine, pseudo-morphine, gnoscopine, xanthaline (papaveraldine), tritopine, hydrocotarnine, porphyroxine (in Indian opium) and possibly others. They exist partly in the free state and partly combined with meconic and sulphuric acids. Meconin, meconoidin and opionin are indifferent substances, present in small proportions only. Other constituents are mucilage, sugar, wax and rubber, together with salts of calcium, magnesium and potassium, but starch, tannin, calcium oxalate and fat do not normally occur, and their presence therefore indicates sophistication. Exhausted with water, undried opium gives an infusion which is acid in reaction, and it yields from 40 to 55 per cent. of dry aqueous extract; the latter contains most of the morphine present in the drug (constituting about 25 per cent. of the extract). The insoluble residue, examined under the microscope, contains not more than insignificant quantities of starch, and small quantities of the outer epidermis of the poppy capsule, portions of which are removed by the scraping,

and are more frequently found in "Druggists'" opium than in any other variety.

Varieties.—Turkey opium is produced in Asia Minor and occurs in rounded, conical, irregular, or flattened masses usually enveloped in poppy leaves, and sometimes more or less covered with the reddish-brown, triangular, winged fruits of a species of *Rumex*, in which the opium is packed in order to prevent the masses from adhering to one another. The weight of the cakes varies from about one ounce to several pounds, the majority of the pieces varying from about 1 to 4 pounds. Turkey opium includes two well-marked commercial varieties, "Soft Shipping" opium and "Druggists'" opium. As its name implies, "Soft Shipping" opium is usually fairly soft, the moisture content being sometimes as high as 30 per cent. or even more. The paste is smooth and homogeneous and varies considerably in colour, and the proportions of morphine and water-soluble matter are both high. "Druggists'" opium possesses a granular structure and is harder than "Soft Shipping" opium, the average moisture content being about 20 to 22 per cent., although it varies considerably and may be as low as 10 per cent. and as high as 25 per cent. The colour ranges from light reddish-brown to dark brown, depending partly upon the age of the drug. The percentage of morphine is appreciably lower than in "Soft Shipping" opium and the water-soluble matter decidedly less. European opium is produced chiefly in Bulgaria, Greece and Yugoslavia. It resembles the "Soft Shipping" variety of Turkey opium in its general characters, but on the average is of appreciably higher quality. Persian opium occurs in brick-shaped masses weighing about 1 pound, or rarely in cones or sticks of varying weight. The bricks are usually wrapped in red paper and tied with red or yellow string, but occasionally white paper is employed. This variety contains, on the average, less moisture than Turkey opium. It is homogeneous in character, and usually contains varying proportions of certain native gums which are added during the manufacture in order to obtain a product having a consistence suitable for moulding into bricks. Indian opium has been produced in two forms. Indian medicinal opium, which is used for medicinal purposes in India, occurs in square blocks weighing about 2 pounds and wrapped in paper which is sometimes oiled. It is dark brown or nearly black in colour, homogeneous, and possesses a somewhat disagreeable odour and a very bitter taste. It varies considerably in consistence, the moisture content ranging from 10 to 18 per cent. Indian smoking opium, as exported to China for many years, occurs in balls, about the size of a small Dutch cheese, which are enveloped in a casing made from poppy petals.

Standard, B.P.—Opium contains in its moist state, as imported, not less than 9.5 per cent. of morphine, calculated as anhydrous. The official description includes only the Turkey and European varieties.

Action and Uses.—The narcotic action of opium is primarily that of morphine, the other alkaloids present being responsible for its secondary effects. The important alkaloids have in all cases a narcotic action, the action decreasing according to the order of the alkaloids in the following series:—Morphine, papaverine, codeine, narcotine, thebaine. On the other hand, the effect on reflexes is a gradually increasing feature of the later members of the group, until in thebaine the stimulating action on the spinal cord entirely overshadows the depressant action on the cerebral hemispheres. The action of opium is exerted less rapidly than that of morphine, as absorption appears to take place less readily. Narcotine and papaverine relax intestinal muscle in contrast to morphine and codeine which increase its tone; this action increases the constipating effect of opium. The

action of opium on the intestine is, therefore, more prolonged and more marked than that of morphine, and on this account preparations of opium are preferred in the treatment of diarrhœa and intestinal disorders.

When opium is prescribed, *Opium Pulveratum* must be dispensed. Powdered opium and the extracts and tincture of opium are the usual forms for internal administration. As a diaphoretic, powdered opium is **administered** in the form of *Pulvis Ipecacuanhæ et Opii* in the early stages of colds, the dose being taken in a cachet, tablet, or powder. For the action of opium on the intestine, *Pilulæ Plumbi cum Opio*, *Pulvis Cretæ Aromaticus cum Opio*, and *Pulvis Kino Compositus* are employed. *Pilulæ Saponis cum Opio* is a sedative; *Pilulæ Ipecacuanhæ cum Scilla*, *Tinctura Opii Camphorata*, and *Tinctura Opii Ammoniata* are expectorants for use in coughs and colds. Lead and opium suppositories are used to relieve rectal and pelvic pain, and gall and opium ointment is a popular application to inflamed piles. Children are very susceptible to the action of opium. To those under the age of five years it should be given only with great caution, and in very small doses. It has been stated that the susceptibility in children applies only to infants still at the breast, and that after one year it appears to pass off. Opium is employed externally as *Linimentum Opii*, or the tincture is added to lotions, often with solution of lead subacetate. The opium alkaloids have, however, no action on motor or sensory nerve endings, and any good effect from their external application is due to absorption. The antidotes for use in cases of **poisoning** by opium are described under Morphina.

Preparations

Extractum Opii Liquidum, B.P.C.—(Ext. Opi Liq.)—Liquid Extract of Opium. It contains from 0·7 per cent. to 0·8 per cent. w/v of anhydrous morphine; 2 millilitres contains about 0·015 gramme, and 30 minims contains about $\frac{1}{2}$ grain, of morphine. Dose.—0·3 to 2 millilitres (5 to 30 minims).

This liquid extract was included in the British Pharmacopœia, 1914.

Extractum Opii Siccum, B.P.—(Ext. Opii Sicc.)—Dry Extract of Opium. *Syn.*—*Extractum opii aquosum I.A.*; *Extractum Opii*. It is prepared with boiling water, and the macerate evaporated to dryness. It is adjusted with calcium phosphate to contain 20 per cent. of anhydrous morphine (limits, 19 to 21); 0·06 gramme contains 0·012 gramme, and 1 grain contains $\frac{1}{2}$ grain, of morphine. It should be stored in small, wide-mouthed, well-closed containers in a cool place. Dose.—0·015 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Linctus Camphoræ Compositus, B.P.C.—(Linct. Camph. Co.)—Compound Linctus of Camphor. Camphorated tincture of opium, 1 in 4, with emulsion of chloroform, syrup of wild cherry, oxymel of squill, solution of bordeaux B and concentrated infusion of senega. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Linctus Scillæ Compositus, B.P.C.—(Linct. Scill. Co.)—Compound Linctus of Squill. *Syn.*—*Linctus Scillæ Opiatus*; *Opiate Linctus of Squill*; *Gee's Linctus*. Equal parts of camphorated tincture of opium, oxymel of squill and syrup of tolu. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linimentum Opii, B.P.C.—(Lin. Opii)—Liniment of Opium. Tincture of opium and liniment of soap, equal parts.

This liniment was included in the British Pharmacopœia, 1914.

Liquor Opii Sedativus, B.P.C.—(Liq. Opii Sed.)—Sedative Solution of Opium.

It contains from 0.95 to 1.05 per cent. w/v of anhydrous morphine; 2 millilitres contains about 0.02 gramme, and 30 minims about $\frac{1}{3}$ grain, of morphine. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Lotio Plumbi cum Opio, B.P.C.—(Lot. Plumb. c. Opio)—Lead and Opium Lotion. Tincture of opium, 1 in 20, in dilute solution of lead subacetate.**Opium Pulveratum, B.P.**—(Opium Pulverat.)—Powdered Opium. *Syn.*—Pulvis Opii; Pulvis opii I.A. Opium in fine or moderately fine powder adjusted with lactose to contain 10 per cent. of anhydrous morphine (limits, 9.5 to 10.5); 0.2 gramme contains 0.02 gramme, and 3 grains contain $\frac{1}{3}$ grain, of morphine. It should be stored in well-closed containers. Dose.—0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains).**Pilulæ Hydrargyri cum Creta et Opii, B.P.C.**—(Pil. Hydrarg. c. Cret. et Opii)—Mercury with Chalk and Opium Pills. *Syn.*—Hutchinson's Pills. Each pill contains 1 grain of mercury with chalk and 1 grain of powder of ipecacuanha and opium. Dose.—1 pill.**Pilulæ Ipecacuanhæ cum Scilla, B.P.C.**—(Pil. Ipecac. c. Scill.)—Ipecacuanha Pills with Squill. Each pill contains 2 grains of powder of ipecacuanha and opium, and $\frac{1}{2}$ grain each of squill and ammoniacum. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Ipecacuanhæ cum Scilla.

Pilulæ Plumbi cum Opio, B.P.C.—(Pil. Plumb. c. Opio)—Lead Pills with Opium. Each pill contains $1\frac{1}{2}$ grains of lead acetate and about $\frac{1}{2}$ grain of powdered opium. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Plumbi cum Opio.

Pilulæ Saponis cum Opio, B.P.C.—(Pil. Sap. c. Opio)—Soap Pills with Opium. *Syn.*—Pilulæ Saponis Compositæ; Compound Soap Pills. Each pill contains $\frac{1}{2}$ grain of powdered opium and about 1 grain of hard soap. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Saponis Composita.

Pulvis Cretæ Aromaticus cum Opio, B.P.—(Pulv. Cret. Aromat. c. Opio)—Aromatic Powder of Chalk with Opium. Powdered opium, 2.5 per cent., with aromatic powder of chalk. It contains 0.25 per cent. of anhydrous morphine (limits, 0.235 to 0.265); 4 grammes contains 0.01 gramme, and 60 grains about $\frac{1}{2}$ grain, of morphine. Dose.—0.6 to 4 grammes (10 to 60 grains).**Pulvis Ipecacuanhæ et Opii, B.P.**—(Pulv. Ipecac. et Opii)—Powder of Ipecacuanha and Opium. *Syn.*—Pulvis opii et Ipecacuanhæ compositus I.A.; Pulvis Ipecacuanhæ Compositus; Compound Powder of Ipecacuanha; Dover's Powder. Powdered ipecacuanha and powdered opium, of each 10 per cent., with lactose. It contains 1 per cent. of anhydrous morphine (limits, 0.95 to 1.05); 0.6 gramme contains 0.006 gramme, and 10 grains contains $\frac{1}{10}$ grain, of morphine. Dose.—0.3 to 0.6 gramme (5 to 10 grains).**Pulvis Kino Compositus, B.P.C.**—(Pulv. Kino Co.)—Compound Powder of Kino. Kino, 75 per cent., and powdered opium, 5 per cent., with cinnamon. Dose.—0.3 to 1.2 grammes (5 to 20 grains).

This powder was included in the British Pharmacopæia, 1914.

Pulvis Opii Compositus, B.P.C.—(Pulv. Opii Co.)—Compound Powder of Opium. Powdered opium, 1 in 10, with pepper, ginger, caraway, and tragacanth. Dose.—0.3 to 1 gramme (5 to 15 grains).

This powder was included in the British Pharmacopæia, 1914.

Suppositorium Plumbi cum Opio, B.P.—(Supp. Plumb. c. Opio)—Suppository of Lead with Opium. *Syn.*—Suppositorium Plumbi Compositum. Each suppository contains 0.2 gramme (3 grains) of lead acetate and 0.06 gramme (1 grain) of powdered opium, equivalent to about 0.006 gramme ($\frac{1}{10}$ grain) of anhydrous morphine.

Tabellæ Plumbi cum Opio, B.P.C.—(Tab. Plumb. c. Opio)—Tablets of Lead with Opium. Each tablet contains 3 grains of lead acetate, $\frac{1}{2}$ grain of powdered opium, and sucrose. Dose.—1 tablet.

Tinctura Opii, B.P.—(Tinct. Opii)—Tincture of Opium. *Syn.*—Laudanum. It is prepared by extracting opium with boiling water and alcohol. It contains 1 per cent. w/v of anhydrous morphine (limits, 0.95 to 1.05); 2 millilitres contains 0.02 gramme, and 30 minims contains about $\frac{1}{2}$ grain, of morphine. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Tinctura opii I.A. is prepared with alcohol (70 per cent.) and contains 1 per cent. of anhydrous morphine. Sirupus opii I.A. contains 0.05 per cent. of anhydrous morphine. Sirupus opii dilutus seu Sirupus diacodii I.A. contains 0.01 per cent. of anhydrous morphine.

Tinctura Opii Ammoniata, B.P.C.—(Tinct. Opii Ammon.)—Ammoniated Tincture of Opium. Tincture of opium, 1 in 10, and solution of ammonia, 1 in 5, with benzoic acid and oil of anise. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

Tinctura Opii Camphorata, B.P.—(Tinct. Opii Camph.)—Camphorated Tincture of Opium. *Syn.*—Tinctura opii benzoica I.A.; Tinctura Camphoræ Composita; Compound Tincture of Camphor; Paregoric; Paregoric Elixir. Tincture of opium, 5 per cent. v/v, with benzoic acid, camphor, oil of anise and alcohol (60 per cent.). It contains 0.05 per cent. w/v of anhydrous morphine (limits 0.045 to 0.055); 4 millilitres contains 0.002 gramme, and 1 fluid drachm contains about $\frac{3}{7}$ grain, of morphine. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Opii Crocata, B.P.C.—(Tinct. Opii Croc.)—Tincture of Opium with Saffron. *Syn.*—Sydenham's Laudanum. It is prepared from opium, cinnamon, clove and saffron and contains from 0.95 per cent. to 1.05 per cent. w/v of anhydrous morphine; 2 millilitres contains about 0.02 gramme, and 30 minims contains about $\frac{1}{2}$ grain, of morphine. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Unguentum Gallæ cum Opio, B.P.C.—(Ung. Gall. c. Opio)—Gall and Opium Ointment. *Syn.*—Unguentum Gallæ Compositum. Powdered opium, 7.5 per cent., in gall ointment.

This ointment was included in the British Pharmacopœia, 1914.

ORTHOCAINA

(Orthocain.)

Orthocaine

Orthocaine, $\text{HO} \cdot \text{C}_6\text{H}_3(\text{NH}_2) \cdot \text{COOCH}_3$, is the methyl ester of *m*-amino-*p*-hydroxybenzoic acid. It may be prepared by reducing the product of nitration of *p*-hydroxybenzoic acid and esterifying with methyl alcohol. Orthocaine occurs as an odourless and tasteless, white or yellowish-white, crystalline powder. It is decomposed by boiling with water or by warming with alkalis, with formation of methyl alcohol and *p*-hydroxybenzoic acid or an alkali salt. The saturated aqueous solution gives a fugitive red colour on the addition of ferric chloride solution. On the addition of a 10 per cent. w/v aqueous solution of sodium nitrite to a 5 per cent. solution of orthocaine in

water acidified with hydrochloric acid, the liquid assumes a yellowish colour, and yields an orange-yellow precipitate which deepens to red on exposure to air. A solution of orthocaine in dilute hydrochloric acid may be distinguished from a solution of benzocaine by the absence of a precipitate on the addition of solution of iodine, and from solutions of procaine hydrochloride or amylocaine hydrochloride by the absence of a precipitate on the addition of potassio-mercuric iodide solution.

Slightly **soluble** in water; soluble in alcohol (90 per cent.) (1 in 7), ether (1 in 50); readily soluble in sodium hydroxide solution.

Standard, B.P.—Orthocaine has a melting-point of 141° to 143° . Loss on drying at 100° , not more than 1 per cent. Ash, not more than 0.1 per cent. A 10 per cent. w/v solution in alcohol (90 per cent.) is neutral to litmus, and colourless or not more than faintly yellow. It complies also with a test for absence of chloride.

Action and Uses.—Orthocaine, when applied to abraded surfaces, acts as a local analgesic and antiseptic. It is used as a dusting powder or as an ointment, 10 to 20 per cent. in wool fat or soft paraffin, for application to burns and painful ulcers of the skin, but it has been reported to produce severe irritation and even necrosis, hence it must be used with great care. It has been recommended for internal use to relieve the pain of gastric ulceration, simple or malignant, but in practice no great benefit is observed. As an insufflation, it is applied to the larynx in tuberculous ulceration.

Dose.—0.1 to 0.2 gramme ($1\frac{1}{2}$ to 3 grains).

OS SEPIÆ

(Os Sep.)

Cuttle Fish Bone

Cuttle fish bone is the internal shell of *Sepia officinalis* Linn. (Class Cephalopoda), a large mollusc common around the coasts of Great Britain and abundant in the Mediterranean and Adriatic Seas.

It occurs in ovate, flattened pieces, having two convex surfaces, from 10 to 25 centimetres long, 4 to 8 centimetres broad and a maximum thickness of 15 to 35 millimetres. Each shell has on one side a thin, hard, almost white, chitinous coat, upon which friable, white, calcareous layers have been deposited, which are easily crushed by moderate pressure and retain the form of the indentation. The odour is faint, and the taste saline and earthy.

Cuttle fish bone **contains** calcium carbonate (80 to 85 per cent.), small quantities of sodium chloride and calcium phosphate, and 10 to 15 per cent. of organic matter.

Standard.—Cuttle fish bone yields not more than 0.6 per cent. of acid-insoluble ash.

Cuttle fish bone, in powder (*Pulvis Ossis Sepiæ* : *Pulv. Os. Sep.*), contains the constituents of and complies with the standard for the unground drug.

Uses.—Cuttle fish bone is used as an ingredient of tooth powders.

SEPIA is prepared from the fluid in the ink gland of the cuttle fish by drying the secretion, dissolving it in caustic soda and reprecipitating by the addition of acid. It is used as a homœopathic remedy.

OVOLECITHINUM

(*Ovolecithin.*)

Ovolecithin

Synonym—Lecithin.

Ovolecithin may be prepared from dried egg-yolk by extraction with alcohol or ethyl acetate, and precipitation of the lecithin from the concentrated solution by the addition of acetone. When so prepared, the product consists of a mixture of true lecithin and a similar compound, kephalin. Ovolecithin is a member of the group of bodies known as the "phosphatides" (substances containing fatty acids, nitrogen and phosphorus), which are in turn classed with the fat-like substances known as "lipins." Numerous lecithins occur in nature, differing slightly in composition. Egg-yolk contains about 10 per cent. Lecithins occur in plants, particularly in leguminous seeds. Many plant lecithins contain considerably less phosphorus than ovolecithin. Soya beans contain about 1.6 per cent. of a lecithin which is a commercial article.

Ovolecithin contains about 4 per cent. of phosphorus and 1.8 per cent. of nitrogen. Animal lecithins contain small amounts of cholesterol, while those of plant origin contain phytosterol. Pure ovolecithin is choline distearyl glycerophosphate, and on hydrolysis with alkalis, choline, stearic acid and glycerophosphoric acids are formed. In kephalin, the choline is replaced by aminoethyl alcohol, and one of the stearic acid groups by linolic acid. Ovolecithin occurs as a brown or yellow, translucent, waxy mass, becoming darker on exposure to air.

Soluble in alcohol, ether, chloroform, benzene and light petroleum; insoluble in acetone.

Standard.—Ovolecithin contains not less than 3.5 per cent. of P.

Assay.—Mix about 0.5 gramme, accurately weighed, with 5 grammes of a mixture of equal parts of sodium carbonate and potassium nitrate, cover in a crucible with a layer of sodium carbonate, and ignite; dissolve the residue in dilute nitric acid, make alkaline with solution of ammonia, and add a slight excess of magnesium ammonio-sulphate solution; filter, wash the precipitate with solution of ammonia (2.5 per cent. w/v), ignite, and weigh the residue of $Mg_2P_2O_7$; 1 gramme of residue is equivalent to 0.2786 gramme of P.

Action and Uses.—Ovolecithin is employed chiefly for its action in improving the nutrition of the nervous system. It has a favourable effect on general nutrition, increasing the body weight. It is stated to increase the number of red corpuscles and to raise their hæmoglobin content; it is also, although only when injected, a powerful agent for inducing leucocytosis. It is given in neurasthenia, tuberculosis and malnutrition. Ovolecithin is **administered** as an emulsion or elixir, or in the form of pills, 0.1 gramme ($1\frac{1}{2}$ grains) in each, massed with powdered althæa and a mixture of alcohol and glycerin as excipients. For intramuscular injection, a solution (5 per cent.) in sterilised olive oil is prepared, sometimes with the addition of guaiacol, eucalyptol and iodoform. Preparations for **injection** may be made by mixing the ovolecithin with an oily medium which has been heated at 150° for one hour, and after distributing the final product into sterilised containers, subjecting them to tyndallisation.

Dose.—0.2 to 0.5 gramme (3 to 8 grains).

ACETYLCHOLINA.—Acetylcholine, $(\text{CH}_3)_3\text{N}(\text{OH})\text{CH}_2\cdot\text{CH}_2\cdot\text{O}\cdot\text{CO}\cdot\text{CH}_3$, occurs as a white, hygroscopic, crystalline powder with a saline, bitter taste and a characteristic odour. It is stated to be 100,000 times as active as choline on arterial pressure but only three times as toxic. Acetylcholine hydrochloride is given by subcutaneous or intramuscular injection in doses of 0.02 to 0.2 gramme ($\frac{1}{2}$ to 3 grains) dissolved at the time of use in 5 millilitres of sterilised water; intravenous administration is dangerous. It is employed in the treatment of arterial hypertension, Raynaud's disease and paralytic ileus.

CHOLINA.—Choline, $(\text{CH}_3)_3\text{N}(\text{OH})\text{CH}_2\cdot\text{CH}_2\text{OH}$, may be obtained from ovolecithin or produced synthetically by the interaction of trimethylamine and ethylene oxide in aqueous solution. Choline hydrochloride is administered intravenously in doses of 0.6 gramme (10 grains) dissolved in 180 millilitres of physiological solution of sodium chloride in the treatment of ileus.

Preparations

Elixir Ovolecithini, B.P.C.—(Elix. Ovolecithin.)—Elixir of Ovolecithin. *Syn.*—Elixir Lecithini; Elixir of Lecithin. Each fluid drachm contains 1 grain of ovolecithin with yolk of egg, tincture of lemon, glycerin and distilled water. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Pilulæ Ovolecithini, B.P.C.—(Pil. Ovolecithin.)—Ovolecithin Pills. *Syn.*—Pilulæ Lecithini; Lecithin Pills. Each pill contains $1\frac{1}{2}$ grains of ovolecithin and $\frac{1}{10}$ grain of strychnine hydrochloride. Dose.—1 to 4 pills.

OXYGENIUM

(Oxygen.)

Oxygen

O = 16.000

Oxygen may be prepared by the fractional distillation of liquid air or by the electrolysis of water. If prepared by the former method, the gas will contain a small proportion of argon and a trace of nitrogen; if prepared by the second method it will contain a small proportion of

hydrogen. It is supplied compressed in metal cylinders. Oxygen occurs as a colourless, odourless and tasteless gas. It supports combustion, and causes a glowing splinter of wood to burst into flame when placed in the gas. Oxygen may be distinguished from nitrous oxide by the red fumes produced when it is mixed with an equal volume of nitric oxide.

Standard, B.P.—Oxygen contains not less than 98 per cent. v/v of O_2 . It complies with limit tests for carbon dioxide, halogens, acids or alkalis, and oxidising substances.

Action and Uses.—Oxygen inhalation is indicated principally in anoxæmia, which may be due to impeded respiration, as in pneumonia, pulmonary œdema and bronchitis, to a low hæmoglobin content of the blood, as in anæmia, or to a lack of oxyhæmoglobin, as in carbon monoxide poisoning. It is also of great value in respiratory failure due to post-operative pulmonary complications. During oxygen inhalation it has been observed that there is a fall in temperature, and also a fall in the respiratory and pulse rates. The application of oxygen therapy in cardiac disease is limited, though it may be of service in angina if the attacks are frequent. For this purpose, oxygen in fairly high concentration should be administered during the attack and stopped as soon as the spasms cease. An attack of asthma may be relieved promptly by similar treatment. It should be noted that, when once oxygen therapy has commenced, the supply should be continuous so long as its use is indicated, and the withdrawal of oxygen treatment should be gradual, especially in cases of chronic cyanosis. The concentration of oxygen for inhalation over long periods should be about 50 per cent. at sea level; it must never exceed 60 per cent., except at high altitudes, when as much as 80 per cent. may be necessary, or when the administration is for short periods only. The addition of 1 per cent. or more of carbon dioxide to oxygen stimulates the respiratory centre and causes deeper breathing, and such a mixture is often used with this purpose in view. The addition of much over 2 per cent. of carbon dioxide causes laboured breathing; more than 5 per cent. may be dangerous. Concentrations of 5 per cent. or more have, however, been found of value in the treatment of carbon monoxide poisoning, post-operative collapse, etc. It must not be forgotten that carbon dioxide is given off during respiration, and so precautions must be taken to prevent the carbon dioxide concentration from rising above about 1.5 per cent. The possibility of there being a great accumulation of carbon dioxide naturally depends largely on the type of apparatus used; increased depth of respiration is a sign that the carbon dioxide concentration is increasing.

Oxygen is **administered** in various ways. The most elaborate methods are by means of the "oxygen chamber" and the "oxygen tent." Simpler, but less efficient, methods are by the use of a mask, or by the introduction of a catheter through the nose, and often it is bubbled through warm water, alcohol, or brandy. Metal cylinders containing compressed oxygen should be fitted with a suitable reducing

valve by which the rate of flow of oxygen can easily be controlled. It is very important that the reducing valve should be free from all traces of oil, otherwise a violent explosion may occur. Also, if the reducing valve is of the rubber bellows type, the tap of the reducer should always be opened before opening the main oxygen tap on the cylinder; opening the main tap with the reducing valve tap closed has been known to cause spontaneous fire. Further, when the oxygen chamber is being used, great care must be exercised to prevent persons unthinkingly entering the room with a lighted cigarette or pipe.

PANCREATINUM

(Pancreatin.)

Pancreatin

Pancreatin is a preparation obtained from the pancreas, or sweetbread, of certain animals commonly used for food which contains the enzymes, trypsin, amylase and lipase. It is usually obtained from the pancreas of the pig or ox. Pancreatin may be extracted by macerating one part of pancreas in four parts of alcohol (25 per cent.). It occurs as a somewhat hygroscopic, white or buff-coloured, amorphous powder having a meat-like odour. Its proteolytic activity is destroyed by treatment with more than traces of mineral acids, and it is thereby distinguished from pepsin, which is active only in acid solution; the activity of pancreatin is also destroyed by strong alkalis and by heat. When dissolved in water, it is precipitated by heat, acids, metallic salts, strong alcohol and tannic acid, but not by saturated solution of sodium chloride, in this last respect differing from pepsin. Pancreatin may be identified by its ability to digest fibrin in alkaline solution, and a solution containing pancreatin acquires a red colour when maintained at 38° in the presence of congo-red fibrin at a pH of 8.0. It should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in water, forming a slightly turbid solution; insoluble in alcohol (90 per cent.) and ether.

Standard, B.P.—Pancreatin possesses not less than a minimum activity in respect of trypsin, lipase and amylase.

Action and Uses.—Pancreatin is employed principally as an aid to starch and protein digestion. For this purpose it is useless if given directly after a meal, since the active ferments contained in it are destroyed by acid pepsin solution. It is, therefore, **administered** two to three hours after a meal, when the acidity of the stomach should have diminished somewhat, preferably associated with sodium bicarbonate or, alternatively, in glutoid capsules or tablets which have been rendered insoluble in the stomach. Pancreatin may also be given in the form of *Liquor Pancreatini* about three hours after a meal.

For the preparation of "pre-digested" protein foods, *Liquor Pancreatini*, *Pulvis Pancreatini Compositus* and *Tabellæ Pancreatini* are

used. For peptonising milk, 25 grains of compound pancreatin powder or two pancreatin tablets are added to 5 fluid ounces of tepid water in a flask. One pint of milk, previously heated to 38°, is then added. The temperature of the mixture is maintained at 38° for fifteen minutes and then raised to boiling-point, after which it should be transferred to a cool place until required for use. The peptonised milk should not be used when it has been kept for more than twenty-four hours, or after it has acquired a bitter taste. Alternatively, milk may be peptonised by dissolving 25 grains of compound pancreatin powder or two pancreatin tablets in 5 fluid ounces of tepid water, adding a pint of luke-warm milk, stirring, and allowing the mixture to stand in a warm place for ten to fifteen minutes, or longer if complete peptonisation is desired. At the end of this time heat the milk to boiling-point, allow to cool, and keep standing on ice. The peptonising process can be arrested at any desired stage by boiling the milk and so destroying the pancreatic enzymes. Gruel, arrowroot and other farinaceous articles of diet may be similarly pre-digested. Peptonised beef tea may be prepared by simmering for two hours half a pound of finely-minced lean beef with a pint of water, to which a saltspoonful of sodium bicarbonate has been added. The mixture is cooled to about 60°, two pancreatin tablets, crushed to powder, are added, and the whole set aside in a warm place for two hours, after which it is boiled for five minutes and strained. Such a solution contains a much larger proportion of nutritive material than ordinary beef tea.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

Preparations

Glycerinum Pancreatini, B.P.C.—(Glycer. Pancreatin.)—Glycerin of Pancreatin. Pancreatin, 1 in 10, with glycerin, simple elixir and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Pancreatini, B.P.C.—(Liq. Pancreatin.)—Solution of Pancreatin. *Syn.*—Liquor Pancreatis; Pancreatic Solution. Glycerin of pancreatin, about 1 in 6, with sodium bicarbonate, glycerin, alcohol (90 per cent.) and distilled water. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

The pancreatic solution of the British Pharmacopœia, 1914, was prepared by macerating 250 grammes of the fresh pancreas of the pig with a mixture of 250 millilitres of alcohol (90 per cent.), 200 millilitres of glycerin and sufficient distilled water to produce 1000 millilitres.

Mistura Bismuthi et Pancreatini, B.P.C.—(Mist. Bism. et Pancreatin.)—Mixture of Bismuth and Pancreatin. Each fluid ounce contains 10 grains each of bismuth carbonate and sodium bicarbonate, 4 grains of pancreatin, and 4 minims of dilute hydrocyanic acid, in chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Pulvis Pancreatini Compositus, B.P.C.—(Pulv. Pancreatin. Co.)—Compound Pancreatin Powder. *Syn.*—Peptonising Powder; Pulvis Pancreaticus Compositus. Pancreatin, 1 in 5, with sodium bicarbonate.

Pulvis Pepsini Compositus, B.P.C.—(Pulv. Pepsin. Co.)—Compound Pepsin Powder. Pepsin, about 1 in 6, pancreatin, 1 in 10, and diastase, 1 in 100, with lactic acid, hydrochloric acid and lactose. Dose.—0.6 to 2 grammes (10 to 30 grains).

Tabellæ Pancreatini, B.P.C.—(Tab. Pancreatin.)—Pancreatin Tablets. *Syn.*—Peptonising Tablets. Each tablet contains $2\frac{1}{2}$ grains of pancreatin and 10 grains of sodium bicarbonate.

PAPAINUM

(Papain.)

Papain

Papain is an impure proteolytic enzyme, or mixture of enzymes, prepared from the juice of the unripe fruit of *Carica Papaya* Linn., a native of South America, the West Indies and other tropical parts. The juice is always more or less acrid or even vesicant, but processes for destroying its acidity weaken its digestive properties. Papain may be obtained by adding to the freshly drawn, milky juice twice its volume of alcohol, the precipitate formed being drained and dried. By dissolving the crude papain in water, and reprecipitating with alcohol, it is obtained as a light-coloured product.

Papain occurs as an amorphous, slightly granular powder, varying in colour from white to light brown, nearly odourless, and having a faint pepsin-like taste. It is very liable to deteriorate. It possesses a digestive action on proteins, and is distinguished from other proteoses by acting in slightly acid, alkaline, or neutral media. Its activity is considerably affected by the presence of salts, and the addition of traces of hydrocyanic acid is stated to increase the activity two or threefold. For this reason, statements as to the optimum temperature and the optimum pH are conflicting. It is active between 37° and 70°, and is destroyed at about 80° in solution, although it is stated that the dry powder may be heated to 100° without destruction.

Standard.—The amino-acids, produced by 1 gramme of papain in the assay process, require for neutralisation not less than 20 millilitres of N/10 sodium carbonate. Ash, not more than 1 per cent.

Assay.—Dissolve 4 grammes of soluble casein in 50 millilitres of hot water, cool, neutralise to phenolphthalein, and dilute with water to 100 millilitres. Triturate 0.2 gramme of papain, accurately weighed, with a few millilitres of water, and wash into 30 millilitres of the casein solution; add 10 millilitres of N/10 sodium carbonate, and dilute to 50 millilitres; to 20 millilitres of the mixture add 20 millilitres of water and 20 millilitres of formaldehyde solution neutralised to phenolphthalein, and titrate immediately with N/10 hydrochloric acid using phenolphthalein as indicator. Warm the remainder of the mixture to 37°, and keep at this temperature for six hours; remove 20 millilitres (equivalent to 0.08 gramme of papain), add 20 millilitres of water and 20 millilitres of formaldehyde solution previously neutralised to phenolphthalein, and titrate with N/10 hydrochloric acid to the same end-point as in the previous titration. Calculate, from the difference in the two titrations, the number of millilitres of N/10 sodium carbonate neutralised by the amino-acids formed by 1 gramme of papain.

Action and Uses.—Papain is employed to assist protein digestion in chronic dyspepsia, gastric fermentation and gastritis. Its activity is exerted both in acid and in alkaline solutions. It may be administered in powders, pills, tablets, or cachets, or in solution as Elixir Papaini or

Glycerinum Papaini. Injections of solution of papain have been given to prevent adhesions.

Dose.—0·12 to 0·6 gramme (2 to 10 grains).

Preparations

Elixir Papaini, B.P.C.—(Elix. Papain.)—Elixir of Papain. Each fluid drachm contains about 3 grains of papain with alcohol (90 per cent.), distilled water and aromatic elixir. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Glycerinum Papaini, B.P.C.—(Glycer. Papain.)—Glycerin of Papain. Papain, 9 per cent. w/v, with dilute hydrochloric acid, simple elixir and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Papaini et Iridini, B.P.C.—(Liq. Papain. et Iridin.)—Solution of Papain and Iridin. Each fluid drachm contains 1 grain each of papain and extract of iris, with glycerin, alcohol (90 per cent.) and chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

PAPAVERETUM

(Papaveret.)

Papaveretum

Synonym—Opium Concentratum.

Papaveretum consists of the hydrochlorides of alkaloids of opium. It may be prepared from opium by converting the total alkaloids into the hydrochlorides and adjusting the mixture to contain 50 per cent. of anhydrous morphine, or by mixing suitable proportions of the hydrochlorides of morphine, codeine, papaverine and other principal opium alkaloids. It occurs in powder, varying in colour from white to light brown or brownish-grey, and having a slightly acid reaction to litmus. It gives a purple colour with sulphomolybdic acid, a green colour with ferric chloride solution, and a violet to purple colour when heated with sulphuric acid and a trace of ferric chloride.

Soluble in water (about 1 in 15), more soluble in hot water, less soluble in alcohol.

Standard.—Papaveretum contains not less than 47·5 per cent. and not more than 52·5 per cent. of anhydrous morphine.

Assay.—Take 1 gramme, accurately weighed, wash into a separator with 20 millilitres of water, add 5 millilitres of N/1 sodium hydroxide and 50 millilitres of ether, and shake thoroughly; separate the lower layer and run into a second separator containing 25 millilitres of ether, and again shake well; separate the lower layer and filter, if necessary, through a tightly-packed plug of cotton wool into a 50 millilitre graduated flask; wash the ether in the two separators with a mixture of 2·5 millilitres of N/1 sodium hydroxide and 5 millilitres of water, and then with successive portions of about 5 millilitres of water, filtering if necessary, until 50 millilitres of liquid has been collected. Then proceed as directed in the British Pharmacopœia for the assay of

opium commencing at "Transfer to a small conical flask . . .," but collecting the morphine on a small filter paper instead of on a plug of cotton wool; each millilitre of N/10 sulphuric acid is equivalent to 0.02852 gramme of anhydrous morphine; to the amount indicated by the titration add 0.025 gramme in order to correct for the loss of morphine due to its solubility.

Action and Uses.—Papaveretum has been recommended for use in place of opium, to which it is said to be superior since it may be given hypodermically, and, when given orally, it is regarded as less constipating. Papaveretum is usually **administered** hypodermically, but may be given in tablet form by the mouth. A 2 per cent. solution in a mixture of 3 parts of water and 1 part of glycerin is suitable for internal administration or for hypodermic injection. It is stated to exert a better sedative and soporific action than morphine, and also to have milder secondary effects. It is given with hyoscine as a sedative before the administration of a general anæsthetic; in such cases a smaller quantity of anæsthetic is required, whilst post-operative shock and pain are usually reduced. It is also administered with hyoscine and atropine in the production of partial anæsthesia and twilight sleep. Preparations for **injection** may be sterilised by heating at 100° for thirty minutes. They should be stored protected from light.

Dose.—0.01 to 0.02 gramme ($\frac{1}{10}$ to $\frac{1}{5}$ grain); 0.005 to 0.01 gramme ($\frac{1}{20}$ to $\frac{1}{10}$ grain), by injection.

PAPAVERINA

(Papaverin.)

Papaverine

Papaverine is one of the minor alkaloids of opium, and may be obtained from the mother liquors of opium extract after the separation of morphine and codeine, by precipitation with ammonia, crystallisation from alcohol and final purification through the acid oxalate (melting-point, 196° to 199°), which, unlike that of the accompanying narcotine, is sparingly soluble in alcohol. Papaverine occurs in rhombic prisms or needles, or as a white, crystalline powder, without odour or taste, and is optically inactive. Its solution in alcohol is alkaline to litmus. Many of the colour reactions ascribed to papaverine are said to be due to associated cryptopine, but the following are due to papaverine itself. A solution of 0.01 gramme in 5 millilitres of cold sulphuric acid is colourless, becomes rose-red at 110°, darkens to violet at 200°, and the colour is discharged on the addition of water. Papaverine slowly gives a rose-red colour with sulphuric acid containing solution of formaldehyde. On the addition of potassium ferricyanide to a faintly acid solution of papaverine, a lemon-yellow precipitate of

papaverine ferricyanide is obtained which, when washed and dried, dissolves in sulphuric acid containing formaldehyde, giving a pale blue colour darkening to bluish-violet.

It is sparingly **soluble** in ether and cold alcohol, more soluble in chloroform and hot alcohol; almost insoluble in water.

Standard.—Papaverine melts between 146° and 147° . Ash, not more than 0.1 per cent.

Action and Uses.—Papaverine has an antispasmodic action, but in therapeutic doses it has no effect on normal muscle. It is useful to relieve spasmodic contraction of the muscle of the gastro-intestinal and bronchial tracts. It does not act on the gastric or intestinal secretions, and does not cause constipation; it has given satisfactory results in spasm of the biliary ducts. Papaverine has no action on the heart. It exerts powerful hypotensive action when the hypertension is due to arterial spasm, and is indicated in angina pectoris associated with dyspnoea and insomnia. In asthma and spasmodic coughs, such as whooping cough, this alkaloid has proved effective. It has also mild analgesic properties. Papaverine is usually **administered** as the sulphate or hydrochloride either orally in the form of cachets or tablets, or hypodermically, and may be given with other antispasmodics such as benzyl benzoate or benzyl succinate.

Dose.—0.12 to 0.25 gramme (2 to 4 grains).

PAPAVERINÆ HYDROCHLORIDUM. — Papaverine hydrochloride, $C_{20}H_{21}O_4N \cdot HCl$, may be prepared by the addition of hydrochloric acid to an alcoholic solution of the base or by treating a solution of papaverine oxalate with a solution of calcium chloride. It occurs as a colourless, odourless, crystalline powder. The aqueous solution is acid to litmus. On the addition of a concentrated solution of sodium acetate to a solution of papaverine hydrochloride, a transient opalescence is produced and, on standing, papaverine crystallises out. Papaverine hydrochloride gives the colour reactions described under papaverine; it melts between 210° and 220° . It is soluble (about 1 in 40) in water and in alcohol. Solutions of papaverine hydrochloride may be sterilised by heating at 70° for thirty minutes on three successive days, or by filtration. Dose.—0.12 to 0.25 gramme (2 to 4 grains).

PAPAVERINÆ SULPHAS.—Papaverine sulphate, $(C_{20}H_{21}O_4N)_2 \cdot H_2SO_4$, may be prepared by the addition of sulphuric acid to an alcoholic solution of papaverine. It occurs as a colourless, crystalline powder which is sparingly soluble in water. Solutions of papaverine sulphate may be sterilised by heating at 70° for thirty minutes on three successive days, or by filtration. Dose.—0.12 to 0.25 gramme (2 to 4 grains).

PAPAVERIS CAPSULA

(Papav. Cap.)

Poppy Capsule

Synonym—Poppy Heads.

Poppy capsule consists of the dried fruits of *Papaver somniferum* Linn. (Fam. Papaveraceæ), probably indigenous to Asiatic Turkey, but

now cultivated in England. They are collected before dehiscence has taken place.

The fruits are ovoid or nearly globular in shape, sometimes depressed at the base and apex, 5 to 7.5 centimetres in diameter, crowned with a large stellate stigma with 12 to 15 rays, and contracted at the base to a neck, which is enlarged near the peduncle. The fruit is pale yellowish-brown in colour, often marked with darker spots. From the inner surface of the thin, brittle pericarp, membranous placentæ, equal in number to the rays of the stigma, project into the cavity of the fruit, but do not meet at the centre; dehiscence is by pores just beneath the stigma. The numerous seeds are 1 to 1.25 millimetres long, almost white in colour, reniform, and marked with conspicuous, raised reticulations with straight edges and about 120 microns in width. The capsules are odourless, but have a slightly bitter taste.

Poppy capsule **contains** about 0.1 to 0.3 per cent. of morphine, and traces of narcotine, codeine, papaverine and meconic acid. The seeds are devoid of alkaloid, but contain about 50 per cent. of a drying oil (poppy seed oil); they should be rejected when making galenical preparations of poppy capsule.

Action and Uses.—Poppy capsule is mildly sedative by virtue of the small proportion of the active constituents of opium it contains. It is employed in the preparation of fomentations for bruises, and for dental and other abscesses. Decoctum Papaveris et Anthemidis Forte is similarly employed. Syrupus Papaveris is a mild sedative for use in cough mixtures.

Preparations

Decoctum Papaveris et Anthemidis Forte, B.P.C.—(Dec. Papav. et Anthem. Fort.)—Strong Decoction of Poppy and Chamomile. *Syn.*—Decoctum Papaveris et Anthemidis Concentratum. Chamomile and poppy capsule, of each, 1 in 4, with alcohol (90 per cent.) and distilled water.

Extractum Papaveris Liquidum, B.P.C.—(Ext. Papav. Liq.)—Liquid Extract of Poppy. *Syn.*—Liquor pro Syrupo Papaveris. It contains from 0.16 to 0.18 per cent. w/v of anhydrous morphine; 2 millilitres contains about 0.003 gramme, and 30 minims about $\frac{1}{2}$ grain, of morphine. Dose.—0.6 to 2 millilitres (10 to 30 minims).

Syrupus Papaveris, B.P.C.—(Syr. Papav.)—Syrup of Poppy. Liquid extract of poppy, 1 in 8, in syrup. It contains about 0.02 per cent. w/v of anhydrous morphine; 1 fluid drachm contains about $\frac{1}{8}$ grain. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

PARADICHLORBENZENUM

(Paradichlorbenz.)

Paradichlorbenzene

Paradichlorbenzene, or *p*-dichlorobenzene, may be obtained, together with monochlorobenzene, by the chlorination of benzene, from

which it may be separated by fractional distillation. It occurs in colourless, shining crystals, with a powerful, characteristic odour. It slowly volatilises in the air, and boils at about 172°.

Soluble in benzene, ether and hot alcohol.

Standard.—Paradichlorbenzene melts between 53° and 54°. Ash, not more than 0.1 per cent.

Uses.—Paradichlorbenzene is an insecticide, particularly useful against moths and furniture beetles. For the control of the former, paradichlorbenzene should be scattered between the folds of clothing in a tightly-closed container, such as a trunk, one pound being used for every 10 cubic feet of space. In the control of furniture beetles, the compound is best applied in the form of a paste containing paradichlorbenzene, 5 parts, thick mineral oil, 5 parts, and soap, 2 parts. Applications should be made during the spring.

ORTHODICHLORBENZENUM.—Orthodichlorbenzene, or *o*-dichlorobenzene, is a heavy, colourless liquid, having a characteristic odour. It boils at about 179°. Orthodichlorbenzene is an insecticide used in the control of furniture beetles. The undiluted compound may be sprayed into the holes produced by the beetles in the furniture, or a mixture of orthodichlorbenzene and kerosene may be used in a similar manner. A mixture of orthodichlorbenzene, 9 parts, with soap, 7 parts, and oil of cedar wood, 1 part, is also used for the treatment of wood attacked by the death-watch beetle.

PARADISI GRANA

(Parad. Gran.)

Grains of Paradise

Synonym—Guinea Grains.

Grains of paradise consists of the seeds of *Aframomum Melegueta* Rosc. (Fam. Zingiberaceæ), a herbaceous plant attaining about 1.5 metres in height, indigenous to the West Coast of Africa.

The seeds vary considerably in shape, but are mostly sub-pyramidal with rounded or obtuse angles, and have the paler fibrous remains of the funiculus projecting from the pointed extremity. They are reddish-brown in colour, and measure about 3 millimetres in length, the surface being shiny and minutely papillose. A longitudinal section exhibits a white, starchy perisperm and a central, horny endosperm within which is a pale-coloured embryo, with the radicle pointing towards the funiculus. The seeds have a faintly aromatic odour and an intensely pungent taste.

Grains of paradise contains about 0.3 to 0.7 per cent. of volatile oil, and a yellowish, oily substance, paradol, the pungency of which is not destroyed by boiling with a 2 per cent. solution of potassium hydroxide.

Action and Uses.—Grains of paradise has carminative properties, and is employed in veterinary practice.

PARAFFINUM DURUM

(Paraff. Dur.)

Hard Paraffin

Hard paraffin is a mixture of solid members of the methane series of hydrocarbons, ranging from $C_{21}H_{44}$ to $C_{30}H_{62}$. It is obtained chiefly from the crude tarry oil produced by the destructive distillation of shale. The oil is redistilled, the distillate is shaken with sulphuric acid to remove basic bodies, and then with sodium hydroxide to remove acidic substances. The product is washed and distilled, yielding various burning and lubricating oils, and finally a thick oil which deposits a crude hard paraffin on cooling. It may also be obtained from petroleum. Hard paraffin occurs as a colourless or white, translucent, wax-like, odourless, tasteless solid, frequently showing a crystalline structure; it is slightly unctuous to the touch. When heated strongly in air, it burns with a luminous flame, although not readily. It is characterised by a marked indifference to most chemical reagents.

Insoluble in water and cold alcohol (90 per cent.); soluble in ether and chloroform.

Standard, B.P.—Hard paraffin has a melting-point of 50° to 60° . Ash, not more than 0.05 per cent. It complies also with a test for limit of acidity.

Action and Uses.—Hard paraffin is employed principally in the preparation of ointment bases for use with medicaments that are not required to be absorbed. It may be sterilised by heating at 150° for one hour. Hard paraffin, melting-point 43° to 46° , is used in plastic operations, especially to correct nasal deformities. The substance known as "Paraffin No. 7" is prepared by mixing 25 parts of soft paraffin and 5 parts of olive oil with 67 parts of melted hard paraffin, then adding 1 part of resorcinol dissolved in a little alcohol and, when the mixture has cooled to 55° , adding 2 parts of oil of eucalyptus. The melting-point is about 48° . It is used as a protective covering for burns and wounds. Hard paraffin is also used for embedding substances when cutting microscopical sections.

CERESINA.—Ceresin, or cerasin, is usually a mixture of purified ozokerites, obtained from the naturally occurring solid paraffin found in the neighbourhood of petroleum springs and obtained chiefly in Galicia, with varying proportions of hard paraffin. It occurs as a colourless, odourless, waxy solid, melting between about 60° and 70° . It is insoluble in water, slightly soluble in alcohol (90 per cent.), readily soluble in ether, chloroform and benzene. Ceresin is used as a substitute for white wax and in the manufacture of candles and polishes.

PARAFFINUM LIQUIDUM

(Paraff. Liq.)

Liquid Paraffin

Liquid paraffin is a mixture of liquid hydrocarbons consisting

chiefly of members of the methane series, ranging from $C_{16}H_{34}$ to $C_{21}H_{44}$. It is obtained from petroleum by distilling off most of the lighter fractions and purifying the liquid residue. Liquid paraffin differs somewhat in composition according to the source of the petroleum from which it is obtained. It occurs as a transparent, colourless, oily liquid, free from fluorescence when viewed by daylight, and almost free from odour and taste.

Insoluble in water and alcohol (90 per cent.); soluble in boiling dehydrated alcohol, ether, chloroform, carbon disulphide, amyl alcohol, benzene, light petroleum, oil of turpentine and many fixed and volatile oils.

Standard, B.P.—Liquid paraffin has a specific gravity of 0.880 to 0.895. 50 millilitres at $37^{\circ}8'$ flows from a Redwood viscometer in not less than 260 seconds. Heated with an equal volume of nitrogen-free sulphuric acid in a test-tube in a boiling water-bath for ten minutes, the colour produced is not deeper than pale brown. It complies with limit tests for solid paraffins, sulphur compounds and for acidity.

Action and Uses.—Liquid paraffin is not irritating when applied to mucous surfaces. Given internally, it acts as a lubricant; to the large intestine it has been found of service in hæmorrhoids, chronic colitis, chronic constipation and other intestinal disorders. The desired lubricating property of the oil increases with its viscosity. It is not a food, and cannot, therefore, act as a substitute for cod-liver oil. It is a suitable vehicle in which to suspend insoluble salts, such as calomel, mercury salicylate, etc., for intramuscular injection. For preparing sprays, light liquid paraffin is preferable (see *Paraffinum Liquidum Leve*). Liquid paraffin is used as an emollient to the skin in irritable conditions, and to remove desquamative crusts. It may be used with oil immersion lenses in place of cedar wood oil but is less effective for this purpose. Liquid paraffin is **administered** internally alone, as an emulsion, or with phenolphthalein or magnesium hydroxide. When required for injection, or for application to septic wounds, it may be sterilised by heating at 150° for one hour.

Dose.—7.5 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

PARAFFINUM CHLORINATUM.—Chlorinated paraffin, or chlorcosane, may be prepared by treating liquid paraffin, 20 parts, with potassium chlorate, 0.1 part, and hydrochloric acid, 0.5 part, in a wide-mouthed glass bottle and allowing the mixture to stand until chlorine ceases to be evolved; the mixture is placed in direct sunlight until the odour of chlorine and the yellow colour of the chlorinated oil have disappeared, and is shaken in a separator with a slight excess of sodium carbonate solution; the chlorinated product, is separated, washed with water until free from alkali and dried by means of anhydrous calcium chloride. Chlorinated paraffin is used as a solvent for dichloramine.

Preparations

Emulsio Paraffini Liquidi Alkalina, B.P.C.—(Emuls. Paraff. Liq. Alk.)—Alkaline Emulsion of Liquid Paraffin. Mixture of magnesium hydroxide, 25 per cent. v/v, with emulsion of liquid paraffin with agar. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi Composita, B.P.C.—(Emuls. Paraff. Liq. Co.)—Compound Emulsion of Liquid Paraffin. *Syn.*—Emulsion of Liquid Paraffin with Agar and Phenolphthalein. Emulsion of liquid paraffin with agar containing $1\frac{1}{2}$ grains of phenolphthalein in each fluid ounce. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi cum Agar, B.P.C.—(Emuls. Paraff. Liq. c. Agar)—Emulsion of Liquid Paraffin with Agar. It contains 50 per cent. v/v of liquid paraffin, with agar. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi cum Glycerophosphatibus, B.P.C.—(Emuls. Paraff. Liq. c. Glycerophosph.)—Emulsion of Liquid Paraffin with Glycerophosphates. *Syn.*—Emulsio Petrolei cum Glycerophosphatibus; Emulsion of Petroleum with Glycerophosphates. It contains 50 per cent. v/v of liquid paraffin with the glycerophosphates of calcium, magnesium, iron, sodium and potassium. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi cum Hypophosphitibus, B.P.C.—(Emuls. Paraff. Liq. c. Hypophosph.)—Emulsion of Liquid Paraffin with Hypophosphites. *Syn.*—Emulsio Petrolei cum Hypophosphitibus; Emulsion of Petroleum with Hypophosphites. It contains 50 per cent. v/v of liquid paraffin with 1 grain each of the hypophosphites of calcium and sodium in each fluid drachm. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Emulsio Paraffini Liquidi et Kaolini, B.P.C.—(Emuls. Paraff. Liq. et Kaolin.)—Emulsion of Liquid Paraffin and Kaolin. It contains liquid paraffin, 25 per cent. v/v, and kaolin, 18.75 per cent. w/v; each fluid ounce contains 2 fluid drachms of liquid paraffin and about 80 grains of kaolin. Dose.—16 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

Mistura Magnesii Hydroxidi et Paraffini Liquidi, B.P.C.—(Mist. Magnes. Hydrox. et Paraff. Liq.)—Mixture of Magnesium Hydroxide and Liquid Paraffin. Liquid paraffin, 30 per cent. v/v, with mixture of magnesium hydroxide, flavoured with vanillin. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Parogenum, B.P.C.—(Parogen.)—Parogen. *Syn.*—Liquid Parogen; Vasoliment. Liquid paraffin, 40 per cent. v/v, with oleic acid, ammoniated alcohol and alcohol (90 per cent.).

PARAFFINUM LIQUIDUM LEVE

(Paraff. Liq. Lev.)

Light Liquid Paraffin

Synonyms—Spray Paraffin; Paraffinum Liquidum pro Nebulis.

Light liquid paraffin is a mixture of liquid hydrocarbons obtained by distillation from petroleum. It occurs as a transparent, colourless, oily liquid which, when cold, is almost devoid of odour. Light liquid paraffin has a lower specific gravity and a lower viscosity than Paraffinum Liquidum.

Insoluble in water and alcohol (90 per cent.); soluble in boiling dehydrated alcohol, ether and chloroform; miscible with benzene, light petroleum, fixed and volatile oils.

Standard.—Light liquid paraffin has a specific gravity of from 0.835 to 0.850. 50 millilitres at a temperature of 37.8° flows from a Redwood No. 1 viscometer in not less than 60 and not more than 80 seconds. It complies also with the limit tests for sulphur compounds and acidity in Paraffinum Liquidum.

Action and Uses.—Light liquid paraffin is employed as a vehicle for oily spray solutions containing ephedrine, menthol, thymol and the volatile oils. For the preparation of solutions of the alkaloids, arachis oil is preferable, or almond oil, 1 part, may be mixed with light liquid paraffin, 2 parts. Light liquid paraffin is preferred to liquid paraffin for use in sprays since, being less viscous, it is more readily broken up by the spray apparatus into the necessary fine particles for projection into the air passages. It is erroneously regarded as a nutritive application for the hair, and forms the basis of many brilliantines.

PARAFFINUM MOLLE ALBUM

(Paraff. Moll. Alb.)

White Soft Paraffin

White soft paraffin is a mixture of semi-solid hydrocarbons usually obtained from petroleum, and bleached. A similar product may be obtained from the tar produced by the distillation of coal at temperatures below 500°. Products of inferior quality may be obtained by melting together suitable proportions of liquid and hard paraffins. White soft paraffin occurs as a white, soft, translucent mass, unctuous to the touch, and not more than slightly fluorescent when viewed in daylight, even when melted. It is odourless and tasteless.

Insoluble in water and alcohol (90 per cent.); soluble in ether, chloroform, benzene and fixed or volatile oils.

Standard, B.P.—White soft paraffin has a refractive index at 60° of 1.453 to 1.460. Melting-point, 40° to 46°. In other respects it complies with the characters and tests for purity for Paraffinum Molle Flavum.

Action and Uses.—White soft paraffin is used as a basis for medicaments in a similar manner to yellow soft paraffin. It is used in the preparation of paraffin ointment when the latter is used for white ointments. White soft paraffin may be sterilised by heating at 150° for one hour.

Preparations

Parenol, B.P.C.—(Paren.)—Parenol. *Syn.*—Solid Parenol. An emulsion of water in a mixture of wool fat, 15 per cent., and white or yellow soft paraffin, 65 per cent.

Unguentum Paraffini, B.P.—(Ung. Paraff.)—Paraffin Ointment. White beeswax, 2 per cent., and hard paraffin, 8 per cent., in white soft paraffin or yellow soft paraffin. When it is used in a white ointment, it should be prepared with white soft paraffin and when used in a coloured ointment, it should be prepared with yellow soft paraffin.

Unguentum Simplex, B.P.—(Ung. Simp.)—Simple Ointment. Wool fat, 5 per cent., in a mixture of hard and soft paraffins. When it is used in a white ointment it should be prepared with white soft paraffin and when used in a coloured ointment, it should be prepared with yellow soft paraffin.

PARAFFINUM MOLLE FLAVUM

(Paraff. Moll. Flav.)

Yellow Soft Paraffin

Yellow soft paraffin is a mixture of semi-solid members of the methane series, mainly ranging from $C_{15}H_{32}$ to $C_{20}H_{42}$. It is usually obtained from the residue remaining when crude petroleum is distilled. A similar product may be obtained from the tar produced by the distillation of coal at temperatures below 500° , or from shale oil. It occurs as a pale yellow or yellow, soft, translucent, unctuous mass which is not more than slightly fluorescent when viewed in daylight, even when melted. It is free or nearly free from odour and taste.

Insoluble in water and alcohol (90 per cent.); soluble in ether, chloroform, benzene and fixed or volatile oils.

Standard, B.P.—Yellow soft paraffin has a refractive index at 60° of 1.460 to 1.474. Melting-point, 38° to 46° . Ash, not more than 0.05 per cent. It volatilises when heated without emitting an acrid odour. When boiled with alcohol, the alcohol is not coloured yellow and is not rendered acid to litmus. It complies also with a test for absence of fixed oils, soaps and resin.

Action and Uses.—Yellow soft paraffin is not irritating when applied to the skin. It is used as a basis for medicaments which are not intended to be absorbed. It is an excellent emollient, and the best ointment basis for reducible substances, especially mercuric salts. Yellow soft paraffin is employed in the preparation of paraffin ointment when the latter is used for coloured ointments. Paraffin ointment is a protective to the skin; it adheres to the dressing, leaving wounds clean. Ointments prepared with soft paraffin melt at the temperature of the body and soak into the dressing. Yellow soft paraffin with wool fat is the pharmacopœial basis for ointments to be applied to the eyes. It is administered in doses of 4 to 8 grammes (1 to 2 drachms) as a lubricant for the intestinal tract. Yellow soft paraffin may be sterilised by heating at 150° for one hour.

Preparations

Oculentum Simplex, B.P.C.—(Oculent. Simp.)—Simple Eye Ointment Wool fat, 1 in 10, with yellow soft paraffin.

This eye ointment is of the same composition as the basis for Ointments for the Eye of the British Pharmacopœia, 1932.

Parenol, B.P.C.—(Paren.)—Parenol. *Syn.*—Solid Parenol. An emulsion of water in a mixture of wool fat, 15 per cent., and white or yellow soft paraffin, 65 per cent.

Unguentum Paraffini, B.P.—(Ung. Paraff.)—Paraffin Ointment White beeswax, 2 per cent., and hard paraffin, 8 per cent., in white soft paraffin or yellow soft paraffin. When it is used in a white ointment it should be prepared with white soft paraffin, and when used in a coloured ointment it should be prepared with yellow soft paraffin.

Unguentum Simplex, B.P.—(Ung. Simp.)—Simple Ointment. Wool fat, 5 per cent., in a mixture of hard and soft paraffins. When it is used in a white ointment it should be prepared with white soft paraffin, and when used in a coloured ointment it should be prepared with yellow soft paraffin.

PARAFORMALDEHYDUM

(Paraformaldehyd.)

Paraformaldehyde

Paraformaldehyde, $(\text{CH}_2\text{O})_3$, is a solid polymeride of formaldehyde. It may be prepared by evaporating a concentrated aqueous solution of formaldehyde, or by adding to solution of formaldehyde about a fourth of its weight of sulphuric acid. It occurs as a white, amorphous powder, or as a white, friable, amorphous mass, odourless at ordinary temperatures, but having a pungent odour on heating. Its solution in hot water exhibits the chemical properties of formaldehyde. It volatilises at 100° , and is readily converted into formaldehyde when heated to this temperature in the presence of water. The addition of potassium permanganate to a suspension of paraformaldehyde also causes the liberation of formaldehyde. 0.04 gramme warmed with 10 millilitres of sulphuric acid containing 0.2 gramme of salicylic acid produces a deep red colour.

Insoluble in water; soluble in boiling water (with depolymerisation) and solutions of the fixed alkali hydroxides.

Standard.—Paraformaldehyde, determined by the method of the British Pharmacopœia for Liquor Formaldehydi, contains not less than 95 per cent. of $(\text{CH}_2\text{O})_3$; each millilitre of N/1 sodium hydroxide is equivalent to 0.03002 gramme of $(\text{CH}_2\text{O})_3$. Ash, not more than 0.1 per cent. 20 millilitres of water shaken with 1 gramme of paraformaldehyde is neutral to litmus.

Action and Uses.—Paraformaldehyde is employed to disinfect rooms, by vaporising it in a suitable lamp. About 20 grammes of paraformaldehyde are required to disinfect thoroughly 1000 cubic feet of enclosed space. To keep catheters and other surgical instruments aseptic, it is enclosed with them in air-tight containers. It is used whenever formaldehyde is required in solid form, as in tablets or lozenges, for taking internally or for preparing antiseptic solutions. Tablets prepared for disinfecting rooms by vaporisation should be coloured by the addition of a suitable blue dye. Paraformaldehyde suspended in flexible collodion (25 per cent.) has been recommended as an efficacious application for warts.

Preparation

Tabellæ Formaldehydi, B.P.C.—(Tab. Formaldehyd.)—Tablets of Formaldehyde. *Syn.*—Formaldehyde and Menthol Tablets; Formalin Throat Tablets; Formamint Tablets. Each tablet contains about $\frac{1}{4}$ grain of paraformaldehyde and $\frac{1}{8}$ grain of menthol, with citric acid, terpeneless oil of lemon, acacia and sucrose. Dose.—1 or 2 tablets.

PARALDEHYDUM

(Paraldehyd.)

Paraldehyde

Paraldehyde is a mixture of polymerides of acetaldehyde, and may be prepared by treating acetaldehyde with small quantities of sulphuric acid, hydrochloric acid, or zinc chloride; the temperature of the liquid rises with almost complete conversion into paraldehyde. Under different conditions, different mixtures of polymerides may be obtained. Paraldehyde occurs as a colourless, transparent liquid with a strong, characteristic odour and a disagreeable, acrid, pungent and subsequently cooling taste. At a low temperature it solidifies to a crystalline mass. Heated with dilute sulphuric acid, it is converted into acetaldehyde, and when warmed with ammoniacal silver nitrate solution a silver mirror is produced. It should be **stored** in small, well-closed, completely-filled bottles, in a cool place and protected from light. If it has solidified, the whole of the contents of the bottle should be liquefied before use.

Soluble in water (1 in 9); miscible with alcohol (90 per cent.), ether, chloroform and volatile oils.

Standard, B.P.—Paraldehyde has a specific gravity of 0.998 to 1.000. Not more than 10 per cent. v/v distils below 123°, and the remainder distils between 123° and 126°. Melting-point, not below 11°. It complies also with limit tests for acidity, acetaldehyde and peroxidised compounds.

Action and Uses.—Paraldehyde is a hypnotic resembling chloral hydrate in its action, but has a less depressant action on the heart and is more rapidly absorbed. It produces an intoxication similar to that produced by alcohol. Owing to this action, the patient may be excited to the point of delirium, and no sleep may be obtained. Small doses are more liable to be excitant than large doses. It is eliminated in part by the lungs but mainly in the urine. It is especially useful in mental and cardiac diseases and in the delirium of fever, but is contra-indicated in bronchitis and pneumonia owing to its irritating effect on the lungs. It is a valuable remedy in spasmodic asthma, dilating the bronchioles by its depressant action on the medullary vagal centre. Administration over long periods may cause addiction, and may necessitate an increase in the effective dose; it may also give rise to an erythematous rash. Large doses may irritate the alimentary canal owing to its irritating action on the mucous membrane; because of this effect, and owing to its disagreeable taste, paraldehyde is best **administered** dissolved in at least 16 parts of water, the taste being disguised with liquid extract of liquorice, tincture of orange or cinnamon water, or it may be given in capsules. In greater concentration than 1 in 9 it may be suspended with compound powder of tragacanth. For the rapid inducement of general anæsthesia, 6 to 15 millilitres (1½ to 4 fluid drachms) of paraldehyde with an equal amount of ether in 150 millilitres (5 fluid ounces) of physiological solution of sodium

chloride may be injected intravenously; doses up to 45 millilitres ($1\frac{1}{2}$ fluid ounces) in olive oil may be given as an enema. Tetanus has been treated with the same mixture, 5 millilitres (75 minims) being injected intravenously once or twice a day, increasing to 15 millilitres (225 minims). Saline injections should be given alternately. In cases of **poisoning** by paraldehyde, which is due to respiratory failure, oxygen and strychnine may be administered.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ALDEHYDUM.—Acetaldehyde, $\text{CH}_3\cdot\text{CHO}$, may be obtained by the oxidation of ethyl alcohol or synthetically from ethylene. It occurs as a colourless, inflammable liquid with a suffocating odour. Specific gravity, about 0.80; boiling-point, about 21° . It combines with ammonia, forming aldehyde ammonia, $\text{CH}_3\cdot\text{CHO}\cdot\text{NH}_3$. It is miscible with water, alcohol and ether. Aldehyde, when inhaled in concentrated form, causes excitement, anaesthesia and, finally, asphyxia. It is used medicinally as Aldehydum Dilutum, a 15 per cent. v/v solution of aldehyde in alcohol. As an antiseptic inhalation in nasal catarrh and ozæna, one minim of diluted aldehyde is added to two fluid ounces of water at 60° .

ALDEHYDUM DECYLICUM.—Decylic aldehyde, $\text{CH}_3(\text{CH}_2)_8\cdot\text{CHO}$, may be prepared synthetically and occurs as an oily liquid having a specific gravity of 0.828 to 0.834 and a boiling-point of about 212° . It is used in perfumery.

ALDEHYDUM DUODECYLICUM.—Duodecylic aldehyde, or laurinic aldehyde, $\text{CH}_3(\text{CH}_2)_{10}\cdot\text{CHO}$, may be prepared synthetically. It occurs as a solid melting at about 44° and is used in perfumery.

ALDEHYDUM METHYLNONYLICUM.—Methylnonyl aldehyde, $(\text{C}_6\text{H}_{13})(\text{CH}_2)\text{CH}\cdot\text{CH}_2\cdot\text{CHO}$, may be prepared synthetically and occurs as a liquid boiling at about 100° under 12 mm. pressure. It has a powerful aromatic odour, and is used in perfumery.

METALDEHYDUM.—Metaldehyde, $(\text{C}_2\text{H}_4\text{O})_n$, is another polymer of acetaldehyde and occurs as a crystalline solid, insoluble in water, almost insoluble in alcohol and ether, and soluble in hot chloroform and benzene. It sublimes at 100° . Metaldehyde is very inflammable and is used in tablet form for heating purposes. It is poisonous when taken internally and the usual precautions should be observed during storage.

PARATHYROIDEUM

(Parathyroid.)

Parathyroid

Parathyroid consists of the external parathyroid glands of oxen, freed from fat, dried and powdered. The fresh gland yields about one-tenth of its weight of parathyroid, which occurs as a pale yellowish powder, with only a slight odour. The parathyroids are small glands which in most animals are situated in close anatomical relationship to the thyroids. They are composed of epithelium-like cells, either in the form of a compact mass, or divided up into trabeculae by strands of vascular connective tissue. Sometimes these two structures may be observed in different parts of the same gland. Parathyroid should be free, or almost free, from thyroid or thymus tissue. It contains no iodine.

Action and Uses.—In development and function the parathyroids are quite independent of the thyroids. Two functions have been assigned to the parathyroid glands; the regulation of calcium metabolism and the detoxication of certain metabolic poisons. Removal of the parathyroids causes a condition in animals and man of neuromuscular irritability, known as tetany. In tetany following parathyroidectomy there is an excess of guanidine in the blood and urine. The administration of guanidine leads to symptoms identical with those of tetany, and consequently it has been thought that tetany is caused by an excess of guanidine in the blood. In tetany, also, there is a grave diminution of calcium in the blood. Injections of calcium control the spasms. In the treatment of tetany, the most satisfactory results are obtained by the subcutaneous injection of parathyroid extract (see *Extractum Parathyroidei*); parathyroid has also been given by the mouth, but with very variable results. Similarly, parathyroid has been given orally in eclampsia, uræmia, epilepsy, paralysis agitans, and vasomotor disturbances such as angioneurotic œdema and Raynaud's disease, and for the relief of chilblains. It is, however, doubtful if it is possible to raise the calcium content of the blood by the oral administration of parathyroid. Parathyroid has also been employed in chronic toxic conditions resulting from sepsis, in which there is usually some deficiency of ionic calcium in the blood. Such conditions may give rise to varicose ulcers, and to ulcerations of the alimentary canal, and the successful use of parathyroid therapy has been reported. It has also been advocated in rickets in children, in osteomalacia and in sprue. Parathyroid may be **administered** in tablets with calcium lactate, but it is more satisfactory to give parathyroid extract by injection.

Dose.—0·003 to 0·006 gramme ($\frac{1}{20}$ to $\frac{1}{10}$ grain).

Preparations

Tabellæ Parathyroidei et Calcii et Sodii Lactatis, B.P.C.—(Tab. Parathyroid. et Calc. et Sod. Lact.)—Tablets of Parathyroid and Calcium Sodium Lactate. Each tablet contains $7\frac{1}{2}$ grains of calcium sodium lactate and $\frac{1}{40}$ grain of parathyroid. Dose.—1 to 4 tablets.

Tabellæ Parathyroidei et Calcii Lactatis, B.P.C.—(Tab. Parathyroid. et Calc. Lact.)—Tablets of Parathyroid and Calcium Lactate. Each tablet contains 5 grains of calcium lactate and $\frac{1}{40}$ grain of parathyroid. Dose.—1 to 4 tablets.

PEGANUM

(Pegan.)

Harmal

Synonyms—Harmal; Armel; Syrian Rue.

Harmal consists of the dried seeds of *Peganum Harmala* Linn. (Fam. Rutaceæ), a bushy herb growing in North-Western India.

The seeds are of a dull earthy-brown colour, with a reticulated seed coat; they are irregularly angular in shape, varying from segments of a sphere to triangular pyramids. The seeds are from 2.5 to 4 millimetres long and from 1.5 to 3 millimetres broad; the longitudinally cut surface exhibits a greyish-white endosperm, which is oily and encloses a large, straight, yellowish embryo, occupying the whole length of the seed; 100 seeds weigh from 0.23 to 0.25 gramme. The crushed seeds impart to alcohol or to water a blue fluorescence. The drug has an unpleasant odour, becoming heavy and narcotic when crushed, and a bitter taste.

Harmal contains the alkaloids, harmaline, $C_{13}H_{14}ON_2$, harmine, $C_{13}H_{12}ON_2$ (melting-point, 260° to 265°), and harmalol, $C_{12}H_{12}ON_2$. The salts of harmine show a blue fluorescence in aqueous solution. Harmine is identical with an alkaloid known as banisterine or telepathine, obtained from *Banisteria Caapi* Spruce (Fam. Malpighiaceæ), and also with the alkaloid, yageine, from *Hemadictyon amazonicum* Benth. (Fam. Apocynaceæ).

Action and Uses.—The properties of harmal are due to harmine and harmalol which have been employed in malaria and paralysis agitans, and as uterine stimulants.

HARMALOL HYDROCHLORIDUM.—Harmalol hydrochloride has been administered hypodermically in doses of 0.025 gramme ($\frac{1}{4}$ grain), and by the mouth in doses of 0.5 to 0.75 gramme (8 to 12 grains)

HARMINÆ HYDROCHLORIDUM.—Harmine hydrochloride has been administered by injection in doses of 0.02 gramme ($\frac{1}{4}$ grain), the injection being given two or three times a week. The effects are transient and must be augmented by stramonium or hyoscine.

PELLETIERINÆ TANNAS

(Pellet. Tann.)

Pelletierine Tannate

Pelletierine tannate is a mixture of the tannates of the alkaloids, pelletierine, isopelletierine, pseudopelletierine and methylpelletierine, obtained from pomegranate bark. It occurs as a light yellow, amorphous, odourless powder, with an astringent taste, and is soluble in warm dilute acids. When heated, it darkens in colour, becoming brown at about 150° ; at about 165° it softens, and at higher temperatures it is decomposed without melting. The aqueous solution has an acid reaction and reduces silver nitrate solution; it gives a bluish-black colour with ferric chloride solution, and a white precipitate with solutions of salts of lead, mercury and zinc; no precipitate is produced with platinic chloride solution.

Soluble in water (about 1 in 700) and alcohol (90 per cent.) (1 in 80); insoluble in chloroform.

Standard, B.P.—Pelletierine tannate leaves on ignition not more

than 0·1 per cent. of residue. It complies also with a test for absence of many foreign alkaloids.

Action and Uses.—Pelletierine tannate has a specific action on tape-worm and is used as a tænicide; other intestinal worms are less susceptible to its action. Pelletierine tannate may be **administered** in cachets or suspended in water. It should be given on an empty stomach and followed after one or two hours by a brisk purge. The treatment may be preceded by doses of 2 grammes (30 grains) of sodium bicarbonate three times a day for two days.

Dose.—0·12 to 0·5 gramme (2 to 8 grains).

PELLETIERINA.—Pelletierine, or punicine, occurs as a colourless, volatile, oily liquid becoming brown on exposure to the air, and having a peculiar, aromatic odour. It is soluble in water (1 in 23), the solution having a strongly alkaline reaction, and in all proportions of alcohol, ether and chloroform. Pelletierine has properties similar to those of pelletierine tannate, but the latter is preferred on account of its greater insolubility in the stomach and consequent decreased tendency to absorption. Absorption may give rise to symptoms of intoxication resembling those caused by male fern. Dose.—0·12 to 0·5 gramme (2 to 8 grains).

PELLETIERINÆ SULPHAS.—Pelletierine sulphate is mainly a mixture of the sulphates of pelletierine and *isopelletierine*, obtained by converting the total alkaloids of pomegranate into sulphates and precipitating the other alkaloids by saturating the aqueous solution with sodium carbonate. After extraction with chloroform, sodium hydroxide solution is added to the aqueous layer and the pelletierine and *isopelletierine* now precipitated are extracted with chloroform and finally converted into the sulphates. It occurs in the form of colourless crystals which tend to become yellow, and is soluble in water. It is usually administered in conjunction with tannin. Dose.—0·12 to 0·5 gramme (2 to 8 grains).

PEPSINUM

(*Pepsin.*)

Pepsin

Pepsin is a substance containing a proteolytic enzyme present in the gastric juices of animals. It is obtained from the mucous membrane of the stomach of certain animals commonly used for food, particularly the pig, sheep, or calf. It may be prepared by mincing the mucous membrane of the stomach and macerating it in slightly acidified water, or in a mixture of glycerin and water. The pepsin is precipitated from the filtered liquid by the addition of a neutral salt such as ammonium sulphate; the precipitate is suspended in water and freed from the salt by dialysis, and the aqueous solution is evaporated *in vacuo* or scaled.

Pepsin occurs as a colourless or light buff-coloured, amorphous powder, or as translucent granules or scales; it has a faint meat-like odour and a slightly acid or saline taste. It readily absorbs moisture on exposure to air, particularly when in powder, this property being due to the presence of peptone. The activity of pepsin is destroyed by the presence of more than traces of sodium chloride, by boiling, or by heating in a slightly alkaline solution. In very dilute hydrochloric acid

solution, pepsin possesses proteolytic activity; if a solution in N/50 hydrochloric acid is divided into two portions, one of which is boiled, on adding a small quantity of carmine-fibrin to each portion and warming at 38° to 40° for one hour, the unboiled solution is stained red, while the boiled liquid remains almost colourless. Varieties of pepsin are obtainable in commerce which will dissolve up to 10,000 times their weight of coagulated egg albumen. Pepsin may be adjusted to the required strength by admixture with lactose. It should be **stored** in well-closed containers in a cool place.

Soluble in water, forming an opalescent solution; insoluble in alcohol (90 per cent.) and ether.

Standard, B.P.—Pepsin dissolves not less than 2500 times its weight of coagulated egg albumen.

Action and Uses.—The digestive or solvent action of pepsin on proteid substances only occurs in acid solution, 0.4 per cent. of hydrogen chloride being about the optimum strength. It dissolves natural insoluble protein, albumin and fibrin, converting them first into soluble acid albumose, and subsequently into peptone. Pepsin is used in therapeutics to increase the digestive power of the gastric juice when there is a deficiency of ferment. This is known to occur in the aged who suffer from chronic wasting diseases, but there is reason to believe that inactivity of the gastric secretion is more often due to deficiency of acid than to deficiency of ferment, especially in cancer.

Pepsin is best **administered** in mixtures as *Glycerinum Pepsini*. It may also be dispensed in pills, massed with syrup of liquid glucose, or in powders or tablets. Pepsin should not be taken until half an hour after a meal. It should be noted that in the presence of acid, pepsin destroys pancreatin, and that in neutral solution, pancreatin destroys pepsin. Pepsin is immediately destroyed by alkalis, and its activity is not restored by subsequent acidification. Such combinations are therefore therapeutically unsound. Pepsin in solution is **incompatible** with alkalis or alkali carbonates and with preparations of the pancreatic ferments, and, in the presence of more than 0.5 per cent. of hydrogen chloride, its proteolytic activity is inhibited and eventually destroyed.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Elixir Pepsini, B.P.C.—(*Elix. Pepsin.*)—Elixir of Pepsin. Each fluid drachm contains about 5 grains of pepsin, with alcohol (90 per cent.), distilled water and aromatic elixir. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Glycerinum Pepsini, B.P.C.—(*Glycer. Pepsin.*)—Glycerin of Pepsin. Pepsin, 10 per cent. w/v, with hydrochloric acid, glycerin and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This glycerin was included in the British Pharmacopæia, 1914.

Glycerinum Pepsini Fortius, B.P.C.—(*Glycer. Pepsin. Fort.*)—Stronger Glycerin of Pepsin. *Syn.*—Glycerol of Pepsin. Pepsin, 15 per cent. w/v, with dilute hydrochloric acid, glycerin, simple elixir and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Euonymini et Pepsini, B.P.C.—(Liq. Euonym. et Pepsin.)—Solution of Euonymin and Pepsin. Each fluid drachm contains 1 grain of extract of euonymus and 2 grains of pepsin, with hydrochloric acid, alcohol (45 per cent.) and chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Pepticus, B.P.C.—(Liq. Pept.)—Peptic Solution. Stronger glycerin of pepsin, 1 in 8, with dilute hydrochloric acid, alcohol (90 per cent.) and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Mistura Bismuthi Composita Acida cum Pepsino, B.P.C.—(Mist. Bism. Co. Acid. c. Pepsin.)—Compound Acid Mixture of Bismuth with Pepsin. Each fluid drachm contains acid solution of bismuth equivalent to about 5 grains of bismuth sodium tartrate, 1 grain of pepsin, and about $\frac{1}{2}$ minim of liquid extract of nux vomica, with dilute hydrocyanic acid, solution of bordeaux B and double chloroform water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mistura Bismuthi Composita cum Pepsino, B.P.C.—(Mist. Bism. Co. c. Pepsin.)—Compound Bismuth Mixture with Pepsin. Each fluid drachm contains $\frac{1}{2}$ fluid drachm of concentrated solution of bismuth, 1 grain of pepsin, $7\frac{1}{2}$ minims of tincture of nux vomica and 2 minims of dilute hydrocyanic acid, with chloroform, solution of bordeaux B and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Mistura Bismuthi Composita cum Pepsino et Morphina, B.P.C.—(Mist. Bism. Co. c. Pepsin. et Morph.)—Compound Bismuth Mixture with Pepsin and Morphine. Each fluid drachm contains $\frac{1}{10}$ grain of morphine hydrochloride in compound bismuth mixture with pepsin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Pulvis Pepsini Compositus, B.P.C.—(Pulv. Pepsin. Co.)—Compound Pepsin Powder. Pepsin, about 1 in 6, pancreatin, 1 in 10, and diastase, 1 in 100, with lactic acid, hydrochloric acid and lactose. Dose.—0.6 to 2 grammes (10 to 30 grains).

Vinum Pepsini, B.P.C.—(Vin. Pepsin.)—Pepsin Wine. Each fluid drachm contains 2 grains of pepsin, with hydrochloric acid and glycerin, in sherry-type wine. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

PEPTONUM

(Pepton.)

Peptone

Peptone is a mixture of the cleavage products of proteins consisting largely of proteoses with peptones and amino-acids. It may be prepared by the enzymatic degradation of proteins, such as by the action of pepsin on lean meat or blood fibrin in an acid medium at a temperature of about 37°. The reaction is stopped at an appropriate time, in order to produce a material high in proteoses. The solution is neutralised, filtered, and evaporated *in vacuo*. It occurs as a whitish or buff-coloured powder, with a faint, meat-like odour, and completely, or almost completely, soluble in water. It should be free from more than traces of histamine.

Peptone for use in bacteriological media varies in composition in accordance with the purpose for which it is required; it should be free from reducing sugars. For some purposes peptone containing a higher percentage of amino-acids is preferable. Such peptone may be prepared by the tryptic digestion of proteins.

Action and Uses.—Peptone is used for non-specific desensitisation in allergic conditions such as asthma, migraine, hay fever, prurigo, angioneurotic œdema, urticaria, eczema and epilepsy. It is **administered** intramuscularly or intravenously, or orally in tablets, cachets or capsules, or in mixtures. A 5 per cent. w/v solution is used for intravenous injection, and a 7.5 per cent. w/v solution is used for intramuscular injection, the injections being given in a series of graduated doses increasing from 0.2 to 1.5 millilitres. Solutions of peptone for **injection** may be sterilised by heating in an autoclave at 115° for fifteen minutes, by filtration, or by heating at 100° for one hour on three successive days. Peptone is also used as a constituent of culture media in bacteriology.

Dose.—0.3 to 1 gramme (5 to 15 grains); 0.01 to 0.1 gramme ($\frac{1}{8}$ to $1\frac{1}{2}$ grains), by injection.

PEPTONUM BOVINUM.—Beef or dietetic peptone may be prepared by the action of pepsin on minced lean beef in an acid medium. The mixture is kept at a temperature not exceeding 50° until 10 millilitres of the filtered solution ceases to give a precipitate on the addition of 15 millilitres of nitric acid. The solution is then filtered, neutralised with sodium bicarbonate and evaporated *in vacuo*. It occurs as a nearly odourless, white or yellowish-brown powder, or in scales. Aqueous solutions are not coagulated by boiling. Beef peptone is administered in pastilles or lozenges containing 5 grains in each, in enemas in doses of 2 to 4 ounces of solution (1 in 8), and in suppositories of 15, 30, or 60 grains containing 75 per cent. of beef peptone.

STERILISED COWS' MILK is injected intramuscularly in doses of 5 to 10 millilitres (75 to 150 minims) for the production of shock in non-specific protein therapy.

Preparations

Injectio Peptoni, B.P.C.—(Inj. Pepton.)—Injection of Peptone. Peptone, 5 or 7.5 per cent. w/v, in neutral, isotonic, aqueous solution. Dose.—0.2 millilitre (3 minims) gradually increased to 1.5 millilitres (25 minims), by intravenous or intramuscular injection.

Liquor Ferri Peptonatis, B.P.C.—(Liq. Ferr. Pepton.)—Solution of Iron Peptonate. *Syn.*—Solution of Peptonised Iron. It contains the equivalent of about 0.65 per cent. w/v of iron, with peptone, 4 per cent. w/v, and flavouring agents. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Liquor Ferri Peptonatis cum Mangano, B.P.C.—(Liq. Ferr. Pepton. c. Mangan.)—Solution of Iron Peptonate with Manganese. *Syn.*—Solution of Peptonised Iron with Manganese. Each fluid drachm contains about $\frac{1}{2}$ grain of manganese chloride in solution of iron peptonate. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Suppositorium Nutriens, B.P.C.—(Supp. Nutr.)—Nutrient Suppository. *Syn.*—Suppositorium Peptoni; Peptone Suppository. Each suppository contains about 75 per cent. of beef peptone.

PERSIO

(Pers.)

Cudbear

Cudbear is a substance obtained from *Roccella tinctoria* DC., *R. Montagnei* Bél., and other species of *Roccella* (Fam. Roccellaceæ,

Order Ascolichenes), lichens growing chiefly on the Canary Islands, Madagascar and on the African coasts. The lichens are digested with about three times their weight of solution of ammonia at 60° for from three days to a week, air being admitted as considered requisite. The mixture assumes first a blue and subsequently a red colour and the product is dried and ground.

Cudbear occurs as a purplish-red powder which imparts a rich red colour to acid and neutral liquids; the colour is again changed to purplish-red on the addition of alkalis. Little definite is known of the constituents of cudbear; probably the colouring principles belong to the oxazine or oxazone group.

Uses.—Cudbear is employed as a colouring agent, especially in the preparation of syrups having an acid reaction. It imparts a bright red colour to such solutions, which changes to purple when alkalis are added. It may be used in the form of a solution or decoction prepared by boiling the fine powder with distilled water for ten minutes, straining and diluting with water if necessary, or in the form of *Tinctura Persionis*.

LITMUS is a blue pigment obtained from various lichens, chiefly *Roccella tinctoria* DC., *R. Montagnei* Bél., *Ochrolechia tartarea* Linn. and *Dendrographa leucophaea* Darbish. The coarsely powdered lichen is mixed with pearl ash and ammonium carbonate solution and submitted for a few weeks to a slow process of fermentation, during which a red colouring matter is produced which gradually changes to blue. Chalk and gypsum are then added, the mixture is passed through a sieve, formed into small rectangular cakes and dried. Litmus occurs in dark blue or bluish-violet, finely granular, friable and slightly aromatic, rectangular cakes or irregular pieces about 3 to 10 millimetres in the greatest dimension. Litmus contains several colouring matters, namely, azolitmin, erythrolitmin, erythrolein and spaniolitmin, of which azolitmin and erythrolitmin appear to be the chief, but they are probably not homogeneous substances. The lichens from which litmus is prepared contain lecanoric acid (*R. tinctoria*), erythrin (*R. Montagnei*), and orcin. Lecanoric acid is diorsellinic acid and is converted by alkalis into orsellinic acid; erythrin is erythrityl orsellinate and may be converted into erythritol and orsellinic acid. All these substances are colourless. Orsellinic acid yields, by further change, orcin, from which, by the action of air in the presence of ammonium carbonate, the colouring matters are produced. These appear to be oxidation products of amino-orscinol. Litmus also contains large quantities of chalk and gypsum.

ORCHILLA.—Orchil, or archil, is a colouring matter obtained from the same botanical sources as cudbear; it occurs in three forms, extract (liquid archil), crystals and powder. Archil extract is manufactured by steeping the orchella weed in ammonia solution; the liquor which is then separated has little colour, but by a further addition of ammonia solution and agitation for a lengthy period at a temperature of about 50°, a reddish-purple colour develops as the result of oxidation. The extract is a reddish-purple liquid, having an ammoniacal odour and a specific gravity of from about 1.04 to 1.05. Archil crystals and archil powder are obtained by treating the extract with sulphuric acid, dissolving the precipitate in alkali solution and evaporating to dryness. They are completely soluble in water, producing reddish-purple solutions.

Preparation

Tinctura Persionis, B.P.C.—(*Tinct. Pers.*)—Tincture of Cudbear. 1 in 8.

PETROLEUM LEVE

(Petrol. Lev.)

Light Petroleum*Synonyms*—Petroleum Spirit; Petroleum Ether.

Light petroleum is the refined distillate from the lower boiling fractions of natural petroleum, shale oil, or low-temperature tar, or of the products produced by the hydrogenation of coal or the cracking of oils. It consists chiefly of a mixture of saturated hydro-carbons of the methane series. It is a colourless, highly inflammable liquid, having a characteristic odour. Its vapour forms an explosive mixture with air. Fractions boiling at 40° to 50° and 50° to 60° constitute the light petroleum reagents of the British Pharmacopœia.

Soluble in alcohol (about 1 in 16); readily miscible with fixed oils (except castor oil), volatile oils, chloroform, ether and benzene.

Standard.—Not less than 95 per cent. of light petroleum distils between 40° and 60°, the specific gravity of which is from 0.620 to 0.700. Residue on evaporation, not more than 0.002 per cent. w/v. Shaken with an equal volume of sulphuric acid, no colour or foreign odour is developed (absence of carbonisable matter, aromatic and sulphur compounds). 10 millilitres, dissolved in a mixture of alcohol and ether previously neutralised to phenolphthalein, gives an immediate red colouration on the addition of 1 drop of N/10 alcoholic potassium hydroxide solution (limit of acidity).

Action and Uses.—Light petroleum is not absorbed from the unbroken skin, and only slightly, if at all, from wounds. When inhaled it is rapidly taken up by the lungs and exerts a toxic action on the central nervous system, the symptoms being headache, mental confusion, tremor and weakness of voluntary muscle. Complete narcosis may ensue. When taken by the mouth, it does not exert such a poisonous action in adults, owing to its slow absorption and the prompt vomiting that usually occurs. Children are, however, more susceptible. Light petroleum is a valuable insecticide and is useful for the destruction of skin parasites. It has occasionally been used as a vermifuge in doses of 30 minims given as an emulsion. It is used largely as a solvent. Treatment of acute **poisoning** consists in gastric lavage, the administration of stimulants and the application of warmth. If there is any cyanosis, artificial respiration should be employed.

BENZINE.—Benzine is the name given to that portion of crude petroleum distilling below 150° and having a specific gravity below 0.750. It should be carefully distinguished from benzene, C_6H_6 , and from benzol. It is separated by fractional distillation and subsequent refining into various commercial products, such as benzoline or mineral naphtha, boiling-range 70° to 95°, specific gravity about 0.700; ligroin or petroleum naphtha, boiling-range 90° to 120°, specific gravity 0.707 to 0.722; petrol, boiling-range 30° to 150° (or 200°), specific gravity 0.68 to 0.75. Higher fractions of petroleum occur in commerce amongst which are the following: white spirit (turpentine substitute), boiling-range 140° to 220°, specific gravity 0.780 to 0.820; illuminating or solar oils, boiling-ranges 150° to 200°, 200° to 250°, 250° to 300°, specific gravity about 0.753 to 0.864; heavy oils for lubrication, boiling-range above 300°, specific gravity up to 0.860.

PHENACETINUM

(Phenacet.)

Phenacetin*Synonym*—Acetphenetidin.

Phenacetin is aceto-*p*-phenetide, $\text{CH}_3\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{OC}_2\text{H}_5$, and may be prepared by nitrating phenol with slightly diluted nitric acid, or with sulphuric acid and sodium nitrate solution, and distilling the product with steam to remove the *o*-nitrophenol from the less volatile *p*-nitrophenol. The latter is purified and converted, by heating its sodium derivative with ethyl iodide, into *p*-nitrophenetole, which is reduced to *p*-phenetidine; from this, phenacetin is produced by prolonged boiling with glacial acetic acid. Phenacetin occurs in white, glistening, laminar crystals, or as a fine, white, crystalline powder, without odour but with a faintly bitter taste. When phenacetin is boiled with hydrochloric acid, and the solution well diluted with water and filtered, the filtrate gives a violet colour, changing rapidly to ruby-red, on the addition of 1 drop of N/10 potassium dichromate.

Soluble in water (about 1 in 1700), alcohol (90 per cent.) (1 in 21), alcohol (60 per cent.) (1 in 100), ether and chloroform; slightly soluble in glycerin.

Standard, B.P.—Phenacetin has a melting-point of 134° to 136° . Ash, not more than 0.05 per cent. The aqueous solution is neutral to litmus. It complies also with a limit test for readily carbonisable substances, and with tests for absence of acetanilide and *p*-phenetidine.

Action and Uses.—Phenacetin reduces temperature in fever by its action on the heat-regulating mechanism of the central nervous system; its effect is to increase the loss of heat by dilatation of the cutaneous vessels. Phenacetin depresses the nerve centres, especially in the basal ganglia of the brain, producing a diminished sensibility to pain. On this account it is employed largely to relieve headache and rheumatic and neuralgic pains. When the pain is severe phenacetin is of little use. It is usually well tolerated, but large doses may cause sweating; the cyanosis and rash that sometimes follow the administration of acetanilide are rarely observed with phenacetin. Toxic effects due to alteration of the red blood corpuscles and production of methæmoglobin are less often observed with phenacetin than with acetanilide. It is best **administered** in tablets or cachets, or suspended in water with compound powder of tragacanth. It is commonly prescribed with caffeine, which counteracts the tendency to circulatory depression, as in *Tabellæ Phenacetini Compositæ*, a combination which is useful in migraine. Phenacetin is also given as *Phenacetinum Effervescens* or as *Phenacetinum cum Caffeina Effervescens*.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

PHENOCOLLI HYDROCHLORIDUM. — Phenocoll hydrochloride, $\text{CH}_3(\text{NH}_2)\text{CO}\cdot\text{NH}\cdot\text{C}_6\text{H}_4\cdot\text{OC}_2\text{H}_5\cdot\text{HCl}$, aminoaceto-*p*-phenetide hydrochloride, or phenamine, occurs as white, crystalline needles or cubes, or as a white, microcrystalline powder having a sharp, saline, and slightly bitter taste. It is soluble in water (1 in 16), readily in hot water and alcohol. Phenocoll hydrochloride reduces temperature in fever, its action closely resembling that of phenacetin, but it is more rapid in its effects on account of its greater solubility. It is employed chiefly in rheumatic fever, malaria and epidemic influenza. Phenocoll hydrochloride may be administered in mixtures or in cachets, or as effervescent granules. Dose.—0.5 to 1 gramme (8 to 15 grains).

Preparations

Phenacetinum cum Caffeina Effervescens, B.P.C.—(Phenacet. c. Caffein. Efferv.)—Effervescent Phenacetin with Caffeine. Phenacetin, about 1 in 20 and caffeine citrate, about 1 in 60. Dose.—4 to 8 grammes (1 to 2 drachms).

Phenacetinum Effervescens, B.P.C.—(Phenacet. Efferv.)—Effervescent Phenacetin. About 1 in 20. Dose.—4 to 8 grammes (1 to 2 drachms).

Tabellæ Acidi Acetylsalicylici Compositæ, B.P.C.—(Tab. Acid. Acetylsalicyl. Co.)—Compound Tablets of Acetylsalicylic Acid. *Syn.*—Compound Aspirin Tablets. Each tablet contains $3\frac{1}{2}$ grains of acetylsalicylic acid, $2\frac{1}{2}$ grains of phenacetin and $\frac{1}{2}$ grain of caffeine. Dose.—1 or 2 tablets.

Tabellæ Acidi Acetylsalicylici et Opii Compositæ, B.P.C.—(Tab. Acid. Acetylsalicyl. et Opii Co.)—Compound Tablets of Acetylsalicylic Acid and Opium. Each tablet contains 3 grains of acetylsalicylic acid, $1\frac{1}{2}$ grains of phenacetin and 1 grain of powder of ipecacuanha and opium. Dose.—1 to 4 tablets.

Tabellæ Phenacetini Compositæ, B.P.C.—(Tab. Phenacet. Co.)—Compound Phenacetin Tablets. Each tablet contains 4 grains of phenacetin and 1 grain of caffeine. Dose.—1 or 2 tablets.

Tabellæ Phenacetini et Caffeinæ Citratis, B.P.C.—(Tab. Phenacet. et Caffein. Cit.)—Tablets of Phenacetin and Caffeine Citrate. Each tablet contains 4 grains of phenacetin and 1 grain of caffeine citrate. Dose.—1 or 2 tablets.

PHENAZONI SALICYLAS

(Phenazon. Salicyl.)

Phenazone Salicylate

Synonym—Antipyryn Salicylate.

Phenazone salicylate may be prepared by heating on a water-bath a mixture of phenazone and salicylic acid in molecular proportions. The mixture melts, yielding an oily liquid which solidifies on cooling and may be purified by recrystallisation from alcohol. It may also be obtained by shaking an aqueous or chloroform solution of phenazone with an ethereal solution of salicylic acid, when the phenazone salicylate separates slowly in fine crystals. It occurs as colourless, odourless, hexagonal laminæ or as a crystalline powder, having a sweetish, bitter, not disagreeable taste, and an acid reaction. It is decomposed by acids and alkalis

Heated with dilute sulphuric acid it yields salicylic acid, and with sodium hydroxide solution, phenazone is liberated. Its aqueous solution treated with ferric chloride solution gives the violet colouration characteristic of salicylic acid. The aqueous solution becomes milky on the addition of tannic acid, and on adding a few drops of fuming nitric acid it becomes green.

Soluble in water (1 in 240), boiling water (1 in 25), alcohol (1 in 4), ether, chloroform and benzene; slightly soluble in carbon disulphide.

Standard.—Phenazone salicylate contains not less than 57 per cent. of phenazone and not less than 42 per cent. of salicylic acid. Melting-point, 91° to 92°. Ash, not more than 0.1 per cent.

Assay.—For phenazone. Dissolve 1 gramme in 25 millilitres of water, add 10 millilitres of sodium hydroxide solution, and extract completely with chloroform. The chloroform extract on evaporation to dryness leaves not less than 0.57 gramme of a residue which responds to the identity tests for Phenazonum.

For salicylic acid. Dissolve about 1 gramme, accurately weighed, in 50 millilitres of alcohol (60 per cent.) and titrate with N/10 sodium hydroxide, using phenol red as indicator; each millilitre of N/10 sodium hydroxide is equivalent to 0.01380 gramme of salicylic acid.

Action and Uses.—Phenazone salicylate is decomposed in the duodenum into phenazone and salicylic acid. It is prescribed in acute and chronic rheumatism, in sciatica, and as an antipyretic in influenza. It may be **administered** in cachets, or suspended in water with compound powder of tragacanth. The containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

PHENAZONI ACETYSALICYLAS.—Phenazone acetylsalicylate occurs as a white, crystalline powder and is given in doses of 0.5 to 1 gramme (8 to 15 grains) as an antipyretic and antirheumatic.

PHENAZONUM

(Phenazon.)

Phenazone

Synonym—Antipyrin.

Phenazone is 1-phenyl-2 : 3-dimethyl-5-pyrazolone, and may be obtained by the condensation of phenylhydrazine with ethyl acetoacetate, whereby phenylmethylpyrazolone is produced; this is dissolved in methyl alcohol and treated with methyl iodide. It occurs in small, colourless crystals, or as a white, crystalline powder, without

odour but with a slightly bitter taste. It unites directly with acids to form salts, and an acid solution gives a precipitate with potassium-mercuric iodide solution. Chloroform extracts it from alkaline solution but not completely from acid solution. On the addition of solution of tannic acid to an aqueous solution of phenazone, a white precipitate is produced. On the addition of dilute sulphuric acid to a 1 per cent. w/v aqueous solution of phenazone containing a trace of sodium nitrite, a green colouration is produced. On the addition of 1 drop of ferric chloride solution to 2 or 3 millilitres of a 1 in 1000 aqueous solution of phenazone, a deep red colour is produced which changes to light yellow on the addition of dilute sulphuric acid.

Soluble in water (1 in 1·2), alcohol (90 per cent.) (1 in 1·3), chloroform (1 in 1·3) and ether (about 1 in 50).

Standard, B.P.—Phenazone has a melting-point of 111° to 113°. Ash, not more than 0·1 per cent. The 5 per cent. w/v aqueous solution is neutral to litmus.

Action and Uses.—The action of phenazone is similar to that of phenacetin, but, being more soluble in water, phenazone acts more rapidly, although for a shorter time. It is more toxic than phenacetin on account of its more rapid absorption. Phenazone is excreted in the urine unchanged. Its action varies with the dose, and ceases as soon as excretion has taken place. Phenazone is used to reduce temperature in fever; it increases the loss of heat by dilating the cutaneous vessels, and does not diminish the production of heat. It is also a valuable analgesic, diminishing the sensibility to pain, and is employed, often associated with tincture of gelsemium, with great success in neuralgia; it does not seem to act on the cortex of the brain like morphine, but on the basal ganglia. Its antipyretic action is also due to its effect on the basal ganglia (corpus striatum). It is given to children for whooping cough in doses of 0·1 gramme ($1\frac{1}{2}$ grains). It sometimes causes rashes and other untoward symptoms, such as nausea, fainting and collapse, although not so commonly as acetanilide. Phenazone is **administered** in powders, tablets, cachets, capsules, effervescent granules, and mixtures. The addition of aromatic spirit of ammonia to mixtures containing phenazone is recommended as a means of obviating any tendency to fainting and collapse. It is **incompatible** with Spiritus Ætheris Nitrosi or other nitrites in acid solution, also with tannic acid in aqueous solution; with sodium salicylate in the dry state it forms an oily liquid on exposure of the mixed solids to air, and it acts similarly with butylchloral hydrate and betanaphthol. In cases of **poisoning** by phenazone, stimulants should be given and the recumbent position maintained; oxygen may be inhaled.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

PHENAZONI ET CAFFEINÆ CITRAS.—Phenazone and caffeine citrate is a white, crystalline powder, containing 90 per cent. of phenazone, 9 per cent. of caffeine and 1 per cent. of citric acid. It is readily soluble in water (1 in 2), and is used as an analgesic. Dose.—0·5 to 1 gramme (8 to 15 grains).

Preparations

Phenazonum Effervescens, B.P.C.—(Phenazon. Efferv.)—Effervescent Phenazone. *Syn.*—Effervescent Antipyrin. About 1 in 12. Dose.—4 to 8 grammes (1 to 2 drachms).

Phenazonum cum Caffeina Effervescens, B.P.C.—(Phenazon. c. Caffein. Efferv.)—Effervescent Phenazone with Caffeine. *Syn.*—Effervescent Antipyrin with Caffeine. Phenazone, about 1 in 12, and caffeine citrate, about 1 in 60. Dose.—4 to 8 grammes (1 to 2 drachms).

PHENOBARBITONUM

(Phenobarbiton.)

Phenobarbitone

Synonym—Phenobarbital.

Phenobarbitone is 5-phenyl-5-ethylbarbituric acid and may be prepared by condensing the ethyl ester of phenylethylmalonic acid with urea. It occurs as a white, odourless, crystalline powder with a slightly bitter taste. It has an acid reaction, and readily dissolves in solutions of alkali hydroxides or carbonates forming solutions of the alkali derivatives. When boiled with concentrated sodium hydroxide solution, or when fused with caustic alkalis, ammonia is evolved. Phenobarbitone may be distinguished from barbitone by adding a trace of sodium nitrite to a 10 per cent. w/v solution in cold sulphuric acid; an orange colouration is produced.

Soluble in water (about 1 in 1000), alcohol (90 per cent.) (1 in 15), ether and chloroform.

Standard, B.P.—Phenobarbitone has a melting-point of 173° to 177°. Ash, not more than 0.05 per cent. It complies also with a test for absence of phenylbarbituric acid and with limit tests for readily-carbonisable substances, and for neutral and basic substances.

Action and Uses.—Phenobarbitone has properties similar to those of barbitone, but its action is intensified owing to the replacement of an ethyl group by a phenyl group. It is a useful hypnotic and sedative in nervous insomnia, and is also employed to relieve migraine. The toxic action of procaine and other local anæsthetics may be reduced by the previous administration of a dose of phenobarbitone. Phenobarbitone is used more especially in the treatment of epilepsy, but care should be exercised as tolerance is apt to be established, necessitating increase in dosage. Serious relapse has often been observed in epileptic patients following the withdrawal of this drug. It should be noted that there is only a small margin between the maximum therapeutic dose and the minimum lethal dose. Phenobarbitone is contra-indicated in arterio-sclerosis, pulmonary and cardiac disease and in nephritis. In some

individuals a skin rash may be produced by phenobarbitone, necessitating withdrawal of the drug. **Poisoning** by phenobarbitone should be treated as outlined for Barbitonum.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Elixir Phenobarbitoni, B.P.C.—(Elix. Phenobarbiton.)—Elixir of Phenobarbitone. Each fluid drachm contains about $\frac{1}{4}$ grain of phenobarbitone with oils of orange, lemon, coriander and anise, glycerin, compound solution of tartrazine, alcohol (90 per cent.) and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Tabellæ Phenobarbitoni et Theobrominæ, B.P.C.—(Tab. Phenobarbiton. et Theobrom.)—Tablets of Phenobarbitone and Theobromine. Each tablet contains $\frac{1}{2}$ grain of phenobarbitone and 5 grains of theobromine. Dose.—1 or 2 tablets.

PHENOBARBITONUM SOLUBILE

(Phenobarbiton. Solub.)

Soluble Phenobarbitone

Synonyms—Soluble Phenobarbital; Phenobarbitone-Sodium.

Soluble phenobarbitone is the monosodium derivative of 5-phenyl-5-ethylbarbituric acid, and may be prepared by treating phenobarbitone with sodium hydroxide. It occurs as a white, hygroscopic, odourless powder, with a bitter taste. The aqueous solution is alkaline to litmus, and yields a precipitate of phenobarbitone on the addition of hydrochloric acid; on long standing or prolonged boiling, the aqueous solution may yield a precipitate of phenobarbitone. On ignition, soluble phenobarbitone yields a residue of sodium carbonate. Soluble phenobarbitone may be distinguished from soluble barbitone by its ready solubility in alcohol (90 per cent.). It should be **stored** in well-closed containers.

Soluble in water and alcohol (90 per cent.); insoluble in ether and chloroform.

Standard, B.P.—Soluble phenobarbitone contains not less than 95 per cent. of $\text{C}_{12}\text{H}_{11}\text{O}_3\text{N}_2\text{Na}$. It complies also with a limit test for free phenobarbitone, neutral and basic substances.

Action and Uses.—Soluble phenobarbitone has properties similar to those of phenobarbitone, but differs in being freely soluble in water. Solutions for injection may be sterilised by tyndallisation or by filtration. It is **incompatible** with ammonium bromide and other ammonium salts. When the two are dispensed together, a white crystalline precipitate of phenobarbitone is deposited, and the supernatant liquid is alkaline and smells of ammonia.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

PHENOL

(Phenol)

Phenol

Synonyms—Acidum Carbolicum; Carbolic Acid.

Phenol is hydroxybenzene, $\text{C}_6\text{H}_5\text{OH}$, and may be obtained synthetically, or from crude tar in which it occurs to the extent of about 0.5 per cent. The coal tar is fractionally distilled, when the phenol passes over in the fraction distilling between about 170° and 230° together with naphthalene and cresols. The phenol is obtained from the separated aqueous layer after treatment with 20 per cent. sodium hydroxide solution by the addition of acid, and purified.

Phenol occurs in colourless, acicular, deliquescent crystals, or in crystalline masses, which may sometimes become pinkish in colour on keeping. It has a characteristic "carbolic" but not tarry odour, and a sweetish, pungent taste. It has a freezing-point of about 40° , and a boiling-point of about 182° . The "detached crystals" of commerce melt at 39° to 40° , but the "ice crystals" are less pure and have a slightly lower melting-point. On the addition of one or two drops of ferric chloride solution to an aqueous solution, a violet colour is produced; the colour is not produced in alcoholic solution. Solutions of phenol give, on the addition of bromine water, a white precipitate which at first redissolves, but is permanent in the presence of excess of bromine water. At 15° , 100 parts of phenol are liquefied by the addition of 10 parts of water and will dissolve 30 to 40 parts of water, but on the further addition of water the liquid separates into two layers, the one a solution of phenol in water, the other a solution of water in phenol, until 1300 parts of water have been added, when a clear solution of phenol in water is formed. It is readily soluble in alkalis, forming solutions of the alkali phenates. Phenol should be **stored** in well-closed containers in a cool place and protected from light.

Soluble in water (1 in 13), alcohol (90 per cent.) (6 in 1), ether (5 in 1), chloroform (2 in 1), glycerin (3 in 1), liquid paraffin (about 1 in 200) and in fixed and volatile oils.

Standard, B.P.—Phenol contains not less than 98 per cent. of $\text{C}_6\text{H}_6\text{O}$. The 1 in 13 aqueous solution at 15.5° is clear and not more than faintly acid to litmus. Residue on volatilisation on a water-bath, not more than 0.05 per cent.

Action and Uses.—Phenol exerts an antiseptic action which varies not only with its concentration, but with the solvent, the proportion of salts present, and the temperature at which it is used. A 1 per cent. aqueous solution destroys the virulence of septic and putrefactive bacteria and of the tubercle bacillus in a few minutes, but more concentrated solutions are required to destroy resistant spores. Solutions in alcohol or oil are practically without antiseptic action, since its affinity

for the solvent is much greater than for the bacterium, and the germicidal power of phenol in watery solutions diminishes as alcohol is added. Phenol is rapidly absorbed from the alimentary canal or from wounds, and in the tissues it combines with sulphuric acid and is excreted as phenylsulphuric acid. In small doses it is sometimes given for gastric fermentation and, in conjunction with bismuth carbonate, for fermentative diarrhœa; for the former purpose, however, sodium phenolsulphonate and for the latter salol are generally preferred.

Phenol is used **externally** both for antiseptic purposes and for its action as a local anæsthetic in allaying pruritus. It is used for disinfecting instruments, utensils, etc., and for the treatment of wounds. Applied to the skin as a 5 per cent. w/v solution, or stronger, it produces a sensation of burning, followed by numbness, and the skin appears white and opaque from the precipitation of the superficial proteins. The presence of glycerin retards the local action considerably. The strong liquefied substance is applied to acne spots, and is occasionally injected into boils and carbuncles at an early stage. Solutions of phenol should not be applied as dressings to the fingers or toes since gangrene may result. For burns and scalds, a solution of 1 part of crystallised phenol in 20 or 40 parts of olive oil is frequently used. A combination of phenol with camphor is not caustic, does not harm the tissues, and has been employed as a paint to the cervix uteri. As a local anæsthetic in toothache, solid phenol, Collodium Carbolisatum, or Phenol cum Camphora is applied. An aqueous solution is used as a gargle, mouth-wash (preferably in the form of solution of sodium phenate), inhalation (1 in 400 to 500 of water at 60°), or spray (1 in 150 of water). Aqueous solutions of phenol should be coloured with magenta or other suitable red dye, unless otherwise directed. Glycerinum Phenolis is used with an equal quantity of glycerin or glycerin of tannic acid as a paint for inflammatory conditions of the mucous membrane of the mouth and throat; the glycerin limits and prolongs the action of the phenol and weakens its caustic effect. If it is necessary to dilute Glycerinum Phenolis for ear-drops, it should be diluted with glycerin, since dilution with water renders it caustic. Oleum Lubricans is used for lubricating catheters which should previously have been sterilised in aqueous solution of phenol (1 in 20). Phenol Iodisatum is occasionally used as a local application. A 10 to 20 per cent. solution of phenol in equal parts of glycerin and water has been used for the treatment of internal hæmorrhoids by direct injection into the pile mass; a 5 per cent. solution in almond oil has been used for a similar purpose by infiltration into the surrounding mucous membrane.

For internal use, phenol may be **administered** in pills massed with one and a half times its weight of powdered liquorice, half its weight of compound powder of tragacanth, and sufficient syrup of liquid glucose added gradually in very small quantities. It may also be given in the form of mixture (either alone or in combination with sodium bicarbonate or spirit of chloroform) or as a pastille or lozenge (0.03 gramme, $\frac{1}{2}$ grain). It is **incompatible** with salts of iron, and cannot be made

into pills with camphor, thymol, menthol, resins and gum-resins without the use of much absorbent powder. In cases of **poisoning** by phenol, saccharated solution of lime, solution of iodine, caffeine, olive oil or camphorated oil should be administered; the usual amount of camphorated oil is two teaspoonfuls, although larger quantities have sometimes been given. Warmth should be applied to the extremities, and alcoholic stimulants given per rectum or hypodermically. In chronic poisoning, when the phenol has fixed all the available sulphates so that the urine contains only aromatic sulphates, which are not precipitated by barium chloride, sodium sulphate, well diluted, should be injected under the skin. Phenol burns are best treated by the immediate application of glycerin, but olive oil and lime water are also useful.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

CYCLOHEXANOLUM.—Cyclohexanol, $C_6H_{11}OH$, may be obtained by the catalytic hydrogenation of phenol and occurs as a somewhat toxic, oily liquid, having a persistent, camphoraceous odour. It has a specific gravity of about 0.935 to 0.945 and a boiling-range of 155° to 170° . It is miscible with hydrocarbons and is used as a solvent in the manufacture of lacquers and varnishes.

CYCLOHEXANONUM.—Cyclohexanone, $C_6H_{10}O$, may be obtained by the catalytic hydrogenation of phenol and occurs as a colourless oil, having an odour recalling that of peppermint and acetone. It has a specific gravity of about 0.93 to 0.96 and a boiling-range of 150° to 165° . It is miscible with most organic solvents and is used as a solvent in the manufacture of lacquers and varnishes.

CYCLOHEXANYLIS ACETAS.—Cyclohexanyl acetate, $CH_3 \cdot COOC_6H_{11}$, is obtained by the acetylation of cyclohexanol. The pure substance is a solid, but owing to incomplete esterification it occurs in commerce as an oily liquid, having a strong, fruity odour, a specific gravity of about 0.947 to 0.980 and a boiling range of 170° to 180° . It is used as a solvent in the manufacture of lacquers and varnishes.

DIAMINOPHENOLIS HYDROCHLORIDUM.—Diaminophenol hydrochloride, or amidol, $C_6H_3(NH_2)_2OH \cdot 2HCl$, is prepared by the reduction of 2:4-dinitrophenol by means of tin and hydrochloric acid, and combination of the resulting diaminophenol with hydrochloric acid. It occurs as a greyish-white, crystalline powder, readily soluble in water and slightly soluble in alcohol. It gives a yellow colour with ammonia and has been recommended as a substitute for Nessler's reagent. It is used as a photographic developer. Solutions of diaminophenol hydrochloride do not keep well and should be made as required.

TRIPHENYLIS PHOSPHAS.—Triphenyl phosphate, $(C_6H_5O)_3PO$, occurs as a white, crystalline solid melting at about 45° to 48° . It is used as a plasticiser in the manufacture of lacquers and varnishes.

Preparations

Carbasus Phenolis, B.P.C.—(Carbas. Phenol.)—Phenol Gauze. *Syn.*—Carbolic Gauze. It contains from 1 to 3 per cent. of phenol when freshly prepared.

Collodium Carbolisatum, B.P.C.—(Collod. Carbol.)—Carbolised Collodion. A jelly consisting of equal weights of phenol and simple collodion.

Gargarisma Phenolis, B.P.C.—(Garg. Phenol.)—Phenol Gargle. *Syn.*—Gargarisma Acidi Carbolici. Glycerin of phenol, 1 in 20, with distilled water.

Glycerinum Phenolis, B.P.—(Glycer. Phenol.)—Glycerin of Phenol. *Syn.*—Glycerinum Acidi Carbolici. Phenol, 16 per cent. w/w, dissolved in glycerin. *Caution.*—Dilution with water renders it caustic; it may be diluted with glycerin. *Dose.*—0.3 to 1 millilitre (5 to 15 minims).

Liquor Phenolis Alkalinus, B.P.C.—(Liq. Phenol. Alk.)—Alkaline Solution of Phenol. *Syn.*—Solution of Sodium Phenate. Phenol, 10 per cent. w/v, with sodium hydroxide and distilled water. It is used diluted with 20 to 30 parts of water.

Liquor Potassii Phenatis Compositus, B.P.C.—(Liq. Pot. Phenat. Co.)—Compound Solution of Potassium Phenate. *Syn.*—Liquor Potassii Carbolatis Compositus; Compound Solution of Potassium Carbolate. Liquefied phenol, 5 per cent. v/v, with solution of potassium hydroxide, Cologne spirit, saccharin, tincture of quillaia, emulsion of chloroform, solution of bordeaux B and triple rose water.

Liquor Sodii Phenatis Compositus, B.P.C.—(Liq. Sod. Phenat. Co.)—Compound Solution of Sodium Phenate. *Syn.*—Compound Solution of Sodium Carbolate; Phenol Soda. Phenol, about 3 per cent. w/v, with sodium hydroxide, triple orange-flower water, triple rose water, glycerin, solution of bordeaux B and distilled water.

Lotio Phenolis, B.P.C.—(Lot. Phenol.)—Phenol Lotion. *Syn.*—Lotio Acidi Carbolici; Carbolic Acid Lotion. Phenol, 1 in 80, in distilled water, coloured with solution of bordeaux B.

Solutio phenoli I.A. contains 2 per cent. of phenol.

Nebula Iodi Composita, B.P.C.—(Neb. Iod. Co.)—Compound Iodine Spray. Iodine, 1 per cent. w/v, and phenol, 0.5 per cent. w/v, in light liquid paraffin.

Oleum Carbolisatum, B.P.C.—(Ol. Carbol.)—Carbolised Oil. *Syn.*—Carbolic Oil. Phenol, 5 per cent. w/v, in arachis oil.

Oleum Lubricans, B.P.C.—(Ol. Lubric.)—Lubricant Oil. *Syn.*—Lund's Oil; Catheter Oil. Phenol, 5 per cent. w/v, in castor oil and arachis oil.

Phenol cum Camphora, B.P.C.—(Phenol c. Camph.)—Phenol with Camphor. *Syn.*—Phenol Camphor; Carbolic Camphor. Phenol, 25 per cent. w/w, with camphor.

Phenol Iodisatum, B.P.C.—(Phenol Iodisat.)—Iodised Phenol. *Syn.*—Iodised Carbolic Acid. Iodine, 10 per cent. w/v, in liquefied phenol.

Phenol Liquefactum, B.P.—(Phenol Liq.)—Liquefied Phenol. *Syn.*—Acidum Carbolicum Liquefactum. Phenol, 80 per cent. w/w, with water (limits, 78.5 to 81.5) Specific gravity, about 1.063. Boiling-point, gradually rising to a temperature not higher than 183°. When phenol is to be mixed with collodion, fixed oils, or paraffins, melted phenol should be used, not liquefied phenol. It should be stored in well-closed containers and protected from light. Dose.—0.06 to 0.2 millilitre (1 to 3 minims).

Pigmentum Chloralis et Camphoræ Compositum, B.P.C.—(Pig. Chloral. et Camph. Co.)—Compound Chloral and Camphor Paint. Equal weights of chloral hydrate, camphor and phenol.

Stupa Phenolis, B.P.C.—(Stup. Phenol.)—Phenol Tow. *Syn.*—Carbolised Tow. It contains about 5 per cent. of phenol when freshly prepared.

Suppositorium Phenolis, B.P.—(Supp. Phenol.)—Phenol Suppository. *Syn.*—Suppositorium Acidi Carbolici. Each suppository contains 0.06 gramme (1 grain) of phenol.

Trochiscus Phenolis, B.P.—(Troch. Phenol.)—Lozenge of Phenol. *Syn.*—Trochiscus Acidi Carbolici; Phenol Lozenge; Carbolic Acid Lozenge. Each lozenge contains approximately 0.03 gramme ($\frac{1}{2}$ grain) of phenol in a basis coloured with carmine. These lozenges should be stored in well-closed containers in a cool place and protected from light.

Unguentum Phenolis, B.P.—(Ung. Phenol.)—Ointment of Phenol. *Syn.*—Unguentum Acidi Carbolici; Phenol Ointment. Phenol, 3 per cent., in a mixture of white beeswax, lard and hard and soft paraffins.

Unguentum Phenolis Compositum, B.P.C.—(Ung. Phenol. Co.)—Compound Phenol Ointment. *Syn.*—Unguentum Acidi Carbolici Compositum; Compound Carbolic Acid Ointment. Phenol, about 18 per cent., with sulphur, olive oil, yellow beeswax and strong ointment of mercuric nitrate.

Vapor Phenolis Compositus, B.P.C.—(Vap. Phenol. Co.)—Compound Phenol Inhalation. *Syn.*—Vapor Acidi Carbolici Compositus; Compound Carbolic Acid Inhalation. Creosote, 1 per cent. v/v, and oils of eucalyptus and Siberian fir, of each 2 per cent. v/v, in phenol.

PHENOLPHTHALEINUM

(Phenolphthal.)

Phenolphthalein

Phenolphthalein is *pp'*-dihydroxydiphenylphthalide, and may be prepared by heating phenol and phthalic anhydride with sulphuric acid or other condensing agent at a temperature of about 120° for several hours, exhausting the product with boiling water, dissolving the residue in dilute sodium hydroxide solution, filtering and precipitating with acetic acid. The product is decolourised in alcoholic solution by charcoal and precipitated with water, when the precipitated phenolphthalein becomes crystalline on standing. Phenolphthalein occurs as a white or yellowish-white, odourless, tasteless, crystalline or amorphous powder. It may melt at temperatures slightly above 260°. It dissolves in dilute solutions of alkali hydroxides and in solutions of alkali carbonates, giving a red solution which is rendered colourless by the addition of acids. In concentrated sulphuric acid it dissolves, forming a red solution the colour of which disappears on dilution. A red colouration is also given with solution of ammonia, but fades on standing.

Soluble in alcohol (90 per cent.) (1 in 10) and ether; almost insoluble in water.

Standard, B.P.—Phenolphthalein has a melting-point of 254° to 258°. Sulphated ash, not more than 0.05 per cent. Arsenic limit, 2 parts per million. It complies also with a limit test for fluorane.

Action and Uses.—Phenolphthalein is given internally as a purgative. Its action is exerted directly on the intestinal mucous membrane, causing a copious watery secretion. It produces loose motions in from four to six hours, but since some of the drug may be absorbed and is excreted in the bile, purgative effects may continue for several days. Usually, however, it is not absorbed in amounts sufficient to irritate the kidneys or intestines, but cases are on record where the drug appeared to have been absorbed, and backache, albuminuria, and the presence of free hæmoglobin in the urine resulted. It occasionally gives rise to a skin rash. It is especially suitable for delicate persons and for women during pregnancy. It is eliminated chiefly *per rectum*, but some may be eliminated by the kidneys, imparting a red colour to alkaline urine. Phenolphthalein is **administered** in cachets, lozenges, or

tablets, either alone or with aloin and other purgatives, or diffused in liquid paraffin. It is also given with emulsions of liquid paraffin and agar.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparations

Emulsio Paraffini Liquidi Composita, B.P.C.—(Emuls. Paraff. Liq. Co.)—Compound Emulsion of Liquid Paraffin. *Syn.*—Emulsion of Liquid Paraffin with Agar and Phenolphthalein. Emulsion of liquid paraffin with agar, containing $1\frac{1}{2}$ grains of phenolphthalein in each fluid ounce. **Dose.**—4 to 16 millilitres (1 to 4 fluid drachms).

Pilulæ Phenolphthaleini Compositæ, B.P.C.—(Pil. Phenolphthal. Co.)—Compound Phenolphthalein Pills. *Syn.*—Pilulæ Phenaloini. Each pill contains $\frac{1}{4}$ grain of aloin, $\frac{1}{2}$ grain of phenolphthalein, $\frac{1}{8}$ grain of strychnine, $\frac{1}{5}$ grain of dry extract of belladonna and $\frac{1}{5}$ grain of powdered ipecacuanha. **Dose.**—1 or 2 pills.

Tabellæ Phenolphthaleini Compositæ, B.P.C.—(Tab. Phenolphthal. Co.)—Compound Phenolphthalein Tablets. Each tablet contains 1 grain of phenolphthalein, $\frac{1}{100}$ grain of dry extract of belladonna, and $\frac{1}{500}$ grain of strychnine sulphate. **Dose.**—1 to 3 tablets.

PHENOL-RUBRUM

(Phenol-Rub.)

Phenol Red

Synonyms.—Phenolsulphonphthaleinum; Phenolsulphonphthalein.

Phenol red may be prepared by fusing *o*-sulphobenzoic acid with phenol at about 130° until combination is complete. This condensation is accompanied by the formation of by-products, and hence manufacturers usually adopt some form of colour standard in order to obtain uniformity. It occurs as a bright to dark red crystalline powder. It dissolves in solutions of alkali hydroxides or carbonates (including ammonium) with the formation of violet-red to deep red solutions as the concentration increases; the colour of these solutions is changed to orange or yellow by a slight excess of acid, and destroyed by warming with zinc dust. 1 millilitre of a 0.1 per cent. alcoholic solution in 100 millilitres of boiled and cooled distilled water produces a strong red colour when shaken with 0.5 millilitre of N/50 sodium hydroxide.

Soluble in water (about 1 in 1300), alcohol (95 per cent.) (about 1 in 350) and acetone (about 1 in 500); almost insoluble in chloroform and ether.

Standard.—Phenol red loses, on drying at 110°, not more than 1 per cent. of its weight. Sulphated ash, not more than 0.2 per cent. Arsenic limit, 5 parts per million.

Uses.—Phenol red is used as an indicator in the determination of the hydrogen ion concentration of urine, starch and bacteriological culture media. Its excretion after the intravenous injection of 0.006 gramme in 1 millilitre is used as a test of renal function. Not less than 50 per cent. for the first hour, or 75 per cent. for the first and second hours, should be excreted in the urine. It can be detected in the urine and determined colorimetrically by making alkaline with sodium hydroxide solution. Combined with ureteric catheterisation, this test can be applied to each kidney separately. Solutions of phenol red for **injection** may be sterilised by heating in an autoclave or by tyndallisation.

PHOSPHORUS

(Phosphor.)

Phosphorus

P = 31.02

Phosphorus is a solid, non-metallic element, and may be obtained from bone ash or other sources of calcium phosphate by conversion into metaphosphoric acid and subsequent distillation with carbon, or by heating a mixture of calcium phosphate, sand and coke in an electric furnace. It may be purified by treatment with chromic acid and redistillation. It occurs in commerce in the form of cylindrical sticks, which are translucent, colourless or pale yellow, wax-like, brittle at low temperatures but soft and pliable at ordinary temperatures. Specific gravity, about 1.83; melting-point, about 44°; boiling-point, about 287°. Phosphorus oxidises spontaneously in moist air and ignites at a temperature above its melting-point; it volatilises slowly in steam, the vapour being luminous in the dark. It unites directly with oxygen, sulphur, chlorine, iodine, bromine and many metals.

Heated in an inert atmosphere to about 250°, phosphorus is converted into red phosphorus, which is probably a solid solution of white phosphorus in "metallic" or "black" phosphorus. Red phosphorus consists of an apparently amorphous, bright reddish-brown powder without odour, of specific gravity about 2.19; it is not luminous in the dark and does not oxidise spontaneously in moist air. It is not ignited by friction or by heating to temperatures below 200°, and is insoluble in carbon disulphide. It sublimates at about 290°, producing a vapour which condenses into white phosphorus. Six allotropic modifications of phosphorus exist. Phosphorus should be **stored** under water in closed containers and protected from light.

Insoluble in water; soluble in alcohol (90 per cent.) (1 in 350), chloroform (1 in 25), ether (1 in 80), carbon disulphide (2 in 1) and olive oil (1 in 80).

Action and Uses.—Phosphorus in the elemental state is rarely used in medicine. In the treatment of rickets and other bone diseases, it

has been replaced by the inorganic phosphates. It has been used in the treatment of neurasthenia. Phosphorus is absorbed by the intestines and, in the form of vapour, by the lungs. The presence of oils facilitates its intestinal absorption. Owing to its physical characteristics, red phosphorus is practically non-toxic. Oxidation of phosphorus in the body is very slow, and a portion may be excreted unchanged by the bowel and kidneys. It has a generally depressant action on metabolism and a special power of causing degenerative changes in the liver and kidneys.

Phosphorus may be **administered** as *Oleum Phosphoratum*, which may be dispensed readily by mixing it with ten times its volume of almond oil and emulsifying with acacia in the usual way. The oil may also be enclosed in capsules or given with cod-liver oil. *Liquor Phosphori Compositus* is also employed for the administration of phosphorus in liquid form. For administration in pills, *Sevum Phosphoratum* is commonly employed. This preparation may be readily incorporated with extracts, etc., by the addition of compound powder of tragacanth, or powdered soap and liquorice, care being taken to avoid oxidation as far as possible by adding chloroform or carbon disulphide to the mass, a few drops at a time, and mixing with a minimum of friction. Phosphorus pills should be freshly prepared, well varnished, and enclosed in a dark amber-coloured bottle. Phosphorus should not be handled, and must be dispensed with the utmost care. It should be cut under water, and must always be dissolved for dispensing purposes, whether it is to be administered in liquid form or in pills, since solid particles of free phosphorus give rise to acute gastritis.

The symptoms of phosphorus **poisoning**, owing to slow absorption, may be delayed. Abdominal pain and vomiting are usual. Depression and weakness occur, followed, after an interval which may be days or weeks, by jaundice; severe hæmorrhage from all the mucous membranes is sometimes a feature. The course of a fatal case is very similar to that in acute yellow atrophy of the liver. Chronic poisoning usually manifests itself by ulceration of the gums with periostitis of the upper and lower jaws, followed by necrosis, and invasion by the tubercle bacillus. This condition is found in persons subjected to the action of the vapour, the presence of dental sepsis being a predisposing factor. The treatment of acute poisoning is by copper sulphate used as an emetic, followed by stomach lavage with 0·2 per cent. w/v solution of potassium permanganate. Fats and oils should be avoided, but liquid paraffin is said to delay absorption if taken early. Alkalis should be given freely.

Dose.—0·0006 to 0·0025 gramme ($\frac{1}{1000}$ to $\frac{1}{200}$ grain).

Preparations

Liquor Phosphori Compositus, B.P.C.—(*Liq. Phosphor. Co.*)—Compound Solution of Phosphorus. *Syn.*—*Tinctura Phosphori Composita*; Compound Tincture of Phosphorus. Phosphorus, 0·2 per cent. w/v, with chloroform and dehydrated alcohol. *Dose.*—0·2 to 0·8 millilitre (3 to 12 minims).

Oleum Phosphoratum, B.P.C.—(Ol. Phosphor.)—Phosphorated Oil. Phosphorus, 1 per cent. w/w, with oil of lemon, in almond oil. Dose.—0·06 to 0·3 millilitre (1 to 5 minims).

This oil was included in the British Pharmacopœia, 1914.

Pilulæ Damianæ Compositæ, B.P.C.—(Pil. Damian. Co.)—Compound Damiana Pills. Each pill contains 2 grains of extract of damiana and $\frac{1}{10}$ grain each of dry extract of nux vomica and phosphorated suet. Dose.—1 pill.

Pilulæ Phosphori, B.P.C.—(Pil. Phosphor.)—Phosphorus Pills. Each pill contains $\frac{1}{10}$ grain of phosphorus. Dose.—1 to 4 pills.

The mass with which these pills are made was included in the British Pharmacopœia, 1914, under the name of Pilula Phosphori.

Sevum Phosphoratum, B.P.C.—(Sev. Phosphor.)—Phosphorated Suet. Phosphorus, 10 per cent., in suet. Dose.—0·006 to 0·03 gramme ($\frac{1}{10}$ to $\frac{1}{2}$ grain.)

PHYSOSTIGMA

(Physostig.)

Calabar Bean *

Synonym—Ordeal Beans.

Calabar bean consists of the ripe seeds of *Physostigma venenosum* Balf. (Fam. Leguminosæ), a woody climbing plant indigenous to the West Coast of Africa.

The seeds are oblong-reniform in shape, being nearly flat or slightly convex on one margin, but boldly arched on the other. They are dark chocolate-brown in colour, and measure about 25 millimetres long, 18 millimetres broad, and 12 millimetres thick. The hilum occurs as a broad, deep groove, extending nearly the entire length of the curved margin, and passing completely round one end of the seed. The lips of the groove are thickened and paler in colour than the channel, which is black, with a distinct, fine brown furrow in the middle; in it may frequently be found portions of a white, papery funiculus and, at one end, the micropyle appears as a minute perforation. The hard seed coat is somewhat rough, and encloses two firm, white, starchy cotyledons, which are curved so as to enclose between them a large cavity, the air in which causes the seeds to float upon water. The seeds have no characteristic odour or taste.

Calabar bean **contains** physostigmine (eserine). Other alkaloids present in small quantity are eseridine, eseramine, physovenine and geneserine. Eseramine is almost without physiological activity, while physovenine, like physostigmine, is a very powerful miotic. Geneserine has a milder action than physostigmine and is said to be identical with eseridine. The total alkaloid varies from about 0·05 to 0·3 per cent. The seeds also contain the phytosterol, stigmasterol, and an abundance of starch, and yield about 4 per cent. of ash.

Substitutes.—The seeds of *P. cylindrospermum* Holmes, which are nearly cylindrical and have a shorter hilum, of *Mucuna urens* Medic. (horse-eye beans), which are brownish and rounded, of *Entada scandens* Benth. (Garbee beans), which are flattened and discoid, and of *Pentaclethra macrophylla* Benth., which are mussel-shaped, are sometimes met with as substitutes for calabar bean.

Action and Uses.—The properties of calabar bean are virtually those of the alkaloid, physostigmine, and it is used only as the source of this alkaloid and its salts. In cases of **poisoning**, the procedure described under Physostigminæ Salicylas should be followed.

PHYSOSTIGMINÆ SALICYLAS

(Physostig. Salicyl.)

Physostigmine Salicylate

Synonym—Eserine Salicylate.

Physostigmine salicylate, $C_{15}H_{21}O_2N_3, C_6H_4(OH) \cdot COOH$, is the salicylate of an alkaloid, physostigmine, obtained from calabar bean. It may be prepared by neutralising a warm, ethereal solution of physostigmine with an ethereal solution of salicylic acid, which is added until a drop of the liquid produces a faint reddening on moistened blue litmus paper. After the crystals have separated they are collected and dried by gentle heat. Physostigmine salicylate occurs as colourless or faintly yellow, odourless crystals, having a faintly bitter taste and melting, after drying at 100° , at 185° to 187° . The 1 per cent. w/v aqueous solution is neutral to methyl red, but a concentrated alcoholic solution is slightly acid to litmus. Both the salt and its aqueous solution acquire a pink colouration on exposure to air and light, owing to formation of rubreserine; the change is less rapid in faintly acid solutions. The aqueous solution gives with ferric chloride a violet colouration, due to the salicylic acid. In other respects the salt responds to the identity tests given under Physostigminæ Sulphas. It is more stable than the other salts of the alkaloid, but is only sparingly soluble in water. It should be **stored** in well-closed containers and protected from light.

Soluble in water (about 1 in 100) and alcohol (90 per cent.) (about 1 in 12).

Standard, B.P.—Physostigmine salicylate loses, on drying at 100° , not more than 1 per cent. of its weight. Ash, not more than 0.1 per cent. It complies also with a limit test for readily carbonisable substances.

Action and Uses.—The action of physostigmine on involuntary muscle and on secretory glands closely resembles that of pilocarpine. When applied to the eye, it causes great contraction of the pupil; the effect is local, and is due mainly to stimulation of the terminations of the

third nerve; intra-ocular pressure is largely reduced as a result of the contraction. Other plain muscle is affected by physostigmine in much the same way; gastric movements are increased and vomiting may result, and intestinal peristalsis is exaggerated, with production of liquid motions; the movements of the bladder and uterus are augmented, and the bronchioles are constricted. All these effects are antagonised by atropine. A similar stimulation of the peripheral nerve endings in glands results in an increase of their secretions, especially in the case of the sudoriferous, salivary, mucous and lachrymal glands. The action of physostigmine on the circulation is to decrease the pulse rate and raise the blood pressure. It depresses the central nervous system, causing muscular weakness and diminished reflexes. Very large doses excite motor nerve endings and so cause irregular twitchings.

Physostigmine has been employed **internally** for its depressant action on the central nervous system in epilepsy, chorea, etc., but has not proved of much service. It has been given hypodermically, 0.0006 gramme ($\frac{1}{1000}$ grain) every four hours, in tetanus, and in intestinal obstruction to obtain an action of the bowels or to prevent the formation of adhesions after operation by exciting peristalsis. In veterinary practice it is given by hypodermic injection for its purgative action. The chief use of physostigmine is as a miotic; under its influence, the pupil commences to contract in from five to fifteen minutes, reaches the maximum contraction in thirty minutes and remains contracted for more than twelve hours. The muscles regulating accommodation are also affected, but they regain their normal condition in from three to four hours. Physostigmine is employed to correct the dilatation caused by atropine, homatropine, or cocaine. It is used in glaucoma to decrease the intra-ocular pressure, but whether this is brought about by lessening the secretion of fluid or by facilitating its escape is not yet clear. For ophthalmic use, *Guttæ Physostigminæ*, *Oculentum Physostigminæ* and *Lamella Physostigminæ* are employed. Solutions of physostigmine salicylate for **injection** may be sterilised by tyndallisation or by filtration. Solutions should be freshly prepared and protected from light. The containers should comply with the tests for limit of alkalinity of glass. Solutions rapidly become pink in colour; this may be avoided to a great extent by dissolving the salt in a solution of boric acid (3 per cent.). Although it is advisable to avoid discolouration, solutions which have become coloured appear to retain their miotic properties. For internal use it may be **administered** in pills. In cases of **poisoning** by physostigmine or its salts, the stomach should be washed out with 0.2 per cent. w/v solution of potassium permanganate, and atropine and strychnine administered hypodermically.

Dose.—0.0006 to 0.0012 gramme ($\frac{1}{1000}$ to $\frac{1}{800}$ grain).

Preparations

Guttæ Physostigminæ, B.P.C.—(*Gutt. Physostig.*)—Physostigmine Five Drops.
Syn.—*Guttæ Eserinæ*; Eserine Eye Drops. Physostigmine salicylate, . per cent., with boric acid, in sterilised water.

Lamella Physostigminæ, B.P.—(Lamell. Physostig.)—Lamella of Physostigmine. *Syn.*—Lamella of Eserine. Each lamella contains 0.000065 gramme ($\frac{1}{1555}$ grain) of physostigmine salicylate.

Oculentum Physostigminæ, B.P.—(Oculent. Physostig.)—Physostigmine Ointment for the Eye. *Syn.*—Oculentum Eserinæ. Physostigmine salicylate, 0.125 per cent., in simple eye ointment. It should be stored in small, well-closed containers in a cool place and protected from light.

An ointment for the eye, prepared with 0.2 per cent. of physostigmine in white soft paraffin, was included in the British Pharmaceutical Codex, 1923.

PHYSOSTIGMINÆ SULPHAS

(Physostig. Sulph.)

Physostigmine Sulphate

Synonym—Eserine Sulphate.

Physostigmine sulphate is the sulphate of the alkaloid, physostigmine, obtained from calabar bean, and may be prepared by adding sulphuric acid (10 per cent.), drop by drop, to a solution of physostigmine in ether until separation of the crystalline sulphate ceases. The salt is collected, and carefully dried at a temperature of about 40°.

Physostigmine sulphate occurs as a yellowish-white, microcrystalline, very deliquescent, odourless powder, having a bitter taste; it gradually becomes reddened on exposure to air and light, owing to formation of rubreserine, a product of oxidation, which is insoluble in ether, but soluble in chloroform and in carbon disulphide. The aqueous solution, which is colourless at first, becomes pink on keeping, and is neutral or only very faintly acid to litmus. After drying at 100°, it melts at about 145°. With gold chloride it produces a purple colour. With sulphuric acid alone the salt gives only a faint yellow colour, but with sulphuric acid containing a crystal of potassium iodate a light purple colour is produced, changing at once to yellowish-red. A 1 per cent. aqueous solution yields with dilute solution of sodium hydroxide a white precipitate becoming pink; the precipitate dissolves in an excess of the reagent to form a red solution. A few milligrams, treated with several drops of ammonia solution, produces a yellowish-red colouration on warming, and on evaporation leaves a bluish residue which dissolves in alcohol to form a blue solution; if acetic acid is then added, the solution appears blue by transmitted light, but shows a red fluorescence which is intensified on dilution with water. The residue left on evaporation of the ammoniacal solution dissolves in sulphuric acid forming a green solution; on the gradual addition of alcohol the colour changes to red, but reverts to green on evaporation of the alcohol. Physostigmine sulphate should be **stored** in well-closed containers and protected from light.

Soluble in water (4 in 1) and alcohol (2.5 in 1); soluble in chloroform, but not very soluble in ether.

Standard.—Physostigmine sulphate loses, on drying at 100°, not more than 1 per cent. of its weight. Ash, not more than 0.1 per cent. 0.05 gramme, dissolved in 1 millilitre of sulphuric acid, does not acquire more than a faintly yellow colouration (limit of readily carbonisable substances). 0.05 gramme in 2 millilitres of water does not produce a violet colouration on the addition of a drop of ferric chloride solution (limit of salicylic acid).

Action and Uses.—The action of physostigmine and its salts is described under Physostigminæ Salicylas. The sulphate is used in the preparation of eye drops, but its solutions are more liable to change colour on storage and, owing to its deliquescent nature, it is more difficult to handle than the salicylate. Solutions of physostigmine sulphate for **injection** may be sterilised by tyndallisation or by filtration. Solutions should be freshly prepared and protected from light. The containers should comply with the tests for limit of alkalinity of glass. The colouration of the solution can be delayed by the addition of 3 per cent. of boric acid.

Dose.—0.0006 to 0.0012 gramme ($\frac{1}{1000}$ to $\frac{1}{800}$ grain).

PHYSOSTIGMINA.—Physostigmine, or eserine, $C_{15}H_{21}O_2N_3$, occurs in large crystals, melting at about 105°; it is tasteless, levorotatory, and sparingly soluble in water, but readily soluble in alcohol, ether, chloroform, benzene and carbon disulphide. The alkaloid is sometimes employed in the preparation of ointments and oily drops for application to the eye as miotics.

Preparation

Guttæ Physostigminæ Oleosæ, B.P.C.—(Gutt. Physostig. Oleos.)—Eye Drops of Physostigmine in Oil. Physostigmine, 0.5 per cent. w/v, in castor oil.

PHYTOLACCA

(Phytolacc.)

Phytolacca

Synonym—Poke Root.

Phytolacca is the root of *Phytolacca decandra* Linn. (Fam. Phytolaccaceæ), a large herbaceous perennial widely distributed in Eastern and Central North America, and naturalised in Southern Europe. It should be collected in the autumn.

The drug occurs in transverse or longitudinal slices of sparingly-branched, nearly cylindrical roots, rarely exceeding 7 centimetres in diameter. The outer surface is yellowish, reddish, or greyish-brown in colour, longitudinally wrinkled, and marked with narrow, transverse bars of cork; the inner surface, when exposed, is whitish and hard, and the fracture is fibrous. It is odourless, and the taste is sweetish and acrid; the powder is powerfully sternutatory. The smoothed, transverse section exhibits several concentric rings of narrow vascular

bundles alternating with rings of parenchymatous tissue; consequently older roots easily separate into longitudinal fibrous strips, and transverse slices show several concentric ridges of elevated fibrous strands alternating with contracted bands of intervening parenchyma. The most important **microscopical** character is the presence of abundant idioblasts containing bundles of acicular crystals of calcium oxalate; the numerous fibres are thick-walled.

Phytolacca **contains** a very bitter resin, 10 per cent. of a non-reducing sugar, and free formic acid. It has also been said to contain a crystalline, neutral principle (phytolaccin), and traces of an alkaloid (phytolaccine) and phytolaccic acid.

Standard.—Phytolacca contains not more than 5 per cent. of its stem. Ash, not more than 14 per cent.

Phytolacca, in powder (Pulvis Phytolacæ : Pulv. Phytolacc.), contains the constituents and possesses the microscopical characters of Phytolacca, and complies with the limit for ash of the unground drug.

Action and Uses.—Phytolacca has emetic, purgative and mildly narcotic properties, but is rarely used in medicine. The powdered drug is a powerful sternutatory. It has been employed in chronic rheumatism, usually in the form of tincture (1 in 10) or liquid extract (1 in 1).

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

PICRORHIZA

(Picrorh.)

Picrorhiza

Picrorhiza consists of the dried rhizome of *Picrorhiza Kurroa* Royle (Fam. Scrophulariaceæ), a small plant indigenous to the Himalayas.

The rhizomes are greyish-brown, light in weight, more or less cylindrical, about 2.5 to 5 centimetres long and 4 to 8 millimetres thick. The external surface is deeply wrinkled longitudinally, with transverse scars of cataphyllary leaves, numerous small, black buds and an occasional root or root-scar; near the apex may be present the black remains of closely approximate, scaly leaves. The fracture is short; the smoothed, transverse surface exhibits a thin, pale grey cork, a dark, lacunous cortex, a narrow ring of tangentially elongated, pale coloured vascular bundles and a very dark pith. There are present a few loose roots, which are slender and longitudinally wrinkled. The drug is odourless, and has a very bitter taste.

Picrorhiza **contains** the bitter, crystalline glycoside, picrorhizin, which yields picrorhizetin and dextrose on hydrolysis.

Standard.—Picrorhiza contains not more than 2 per cent. of its stems and other foreign organic matter.

Action and Uses.—Picrorhiza is a bitter, and is used as a tonic and antiperiodic. It is best administered as liquid extract [Extractum Picrorhizæ Liquidum, 1 in 1, in doses of 1 to 4 millilitres (15 to 60 minims)], or as tincture [Tinctura Picrorhizæ, 1 in 4 in alcohol (45 per cent.) in doses of 2 to 4 millilitres (30 to 60 minims)], in combination with aromatics.

Dose.—0.6 to 4 grammes (10 to 60 grains).

PICROTOXINUM

(Picrotox.)

Picrotoxin

Picrotoxin may be prepared by exhausting powdered cocculus indicus with boiling alcohol and, after concentration, extracting the fatty residue with hot water; on cooling, picrotoxin crystallises, and may be recrystallised from water or alcohol. It occurs as intensely bitter, poisonous, colourless, odourless, shining, prismatic crystals, or as a microcrystalline powder, melting at about 200° to a yellow liquid. The alcoholic solution is lævorotatory and neutral. Amyl alcohol, benzene and chloroform extract picrotoxin from acid, but not from alkaline solutions. It dissolves in sulphuric acid forming a bright yellow solution; the colour changes to orange-violet on warming and becomes green on the addition of potassium dichromate. On the addition of 1 drop of a 20 per cent. solution of anisaldehyde in dehydrated alcohol to picrotoxin moistened with sulphuric acid, a permanent blue colour is obtained. A mixture of picrotoxin and three times its weight of potassium nitrate develops an intense red colour on moistening with strong sulphuric acid and adding a strong solution of sodium hydroxide. Picrotoxin reduces Fehling's solution and ammoniacal silver nitrate solution, and gives no precipitate with the usual alkaloidal precipitants. It is readily decomposed into picrotoxinin, $\text{C}_{15}\text{H}_{16}\text{O}_6$, and picrotin, $\text{C}_{15}\text{H}_{18}\text{O}_7$.

Soluble in water (1 in 334), boiling water (1 in 35), alcohol (1 in 13.5), boiling alcohol (1 in 3), solution of potassium hydroxide (1 in 10), amyl alcohol, benzene, ether, chloroform and glacial acetic acid.

Action and Uses.—Picrotoxin is a powerful convulsive poison, differing from strychnine in that it acts mainly on the medulla. It is used occasionally to check the profuse night-sweats of phthisis through its action in accelerating respiration, thus removing the partial asphyxia and so preventing stimulation of the nervous mechanism governing perspiration; it is successful only in a limited number of cases. Picrotoxin has been employed in the treatment of epilepsy and chronic alcoholism, and as an antidote in morphine poisoning. In the form of an ointment (1 in 50) it has been used as a parasiticide, but it is too dangerous a substance to use in this way. In cases of **poisoning** by

picROTOXIN, an emetic should be given or the stomach should be washed out, and chloral hydrate and potassium bromide administered.

Dose.—0.0006 to 0.0025 gramme ($\frac{1}{1000}$ to $\frac{1}{200}$ grain).

PILOCARPINÆ HYDROCHLORIDUM

(Pilocarp. Hydrochlor.)

Pilocarpine Hydrochloride

Pilocarpine hydrochloride may be prepared by dissolving the base obtained from the nitrate in sufficient dilute hydrochloric acid to form a neutral solution, concentrating, and setting aside over sulphuric acid to crystallise. It occurs in the form of colourless, odourless crystals, deliquescent in moist air. The aqueous solution has a faintly bitter taste, and is neutral or only faintly acid to litmus. Sulphuric acid dissolves it with liberation of hydrogen chloride and the formation of a colourless liquid; on the addition of a small fragment of potassium dichromate, a bright grass-green colouration is produced. It responds to the test for distinction from other alkaloids given under Pilocarpinæ Nitras. A mixture of equal parts of the salt and calomel becomes blackened when moistened with alcohol.

Freely **soluble** in water, and dehydrated alcohol (1 in 10); almost insoluble in ether and chloroform.

Standard.—Pilocarpine hydrochloride, when dried to constant weight at 100°, melts between 204° and 205°. Specific rotation, determined on a 10 per cent. w/v aqueous solution, +90° to +92°. Ash, not more than 0.1 per cent. It complies with the tests for absence of certain other alkaloids in Pilocarpinæ Nitras.

Action and Uses.—The action of pilocarpine hydrochloride is similar to that of pilocarpine nitrate. Solutions for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The containers must comply with the limit of alkalinity of glass, and the solutions should be stored protected from light.

Dose.—0.003 to 0.012 gramme ($\frac{1}{300}$ to $\frac{1}{80}$ grain).

PILOCARPINÆ HYDROBROMIDUM. — Pilocarpine hydrobromide, $C_{11}H_{16}O_2N_2.HBr$, occurs in the form of white crystals, soluble in water and alcohol and melting at 185°. It is used for the same purposes as pilocarpine hydrochloride. **Dose.**—0.003 to 0.012 gramme ($\frac{1}{300}$ to $\frac{1}{80}$ grain).

Preparation

Syrupus Potassii Bromidi et Pilocarpinæ, B.P.C.—(Syr. Pot. Brom. et Pilocarp.)—Syrup of Potassium Bromide and Pilocarpine. Potassium bromide, 10 per cent. w/v, and pilocarpine hydrobromide, 0.005 per cent. w/v, with glycerin and syrup of orange; each fluid drachm contains about $5\frac{1}{2}$ grains of potassium bromide and $\frac{1}{20}$ grain of pilocarpine hydrobromide. **Dose.** 4 to 8 millilitres (1 to 2 fluid drachms).

PILOCARPINÆ NITRAS**(Pilocarp. Nit.)****Pilocarpine Nitrate**

Pilocarpine nitrate is the salt of an alkaloid, pilocarpine, obtained from the leaves of species of *Pilocarpus*. It occurs in the form of colourless crystals or as a white, crystalline powder, without odour but with a faintly bitter taste. The 5 per cent. aqueous solution is neutral to methyl red, but slightly acid to litmus; it yields no precipitate on the addition of solution of ammonium, sodium, or potassium hydroxide. Pilocarpine salts may be distinguished from the salts of other alkaloids by the following colour reaction. To a few millilitres of a 1 in 500 aqueous solution, acidified by the addition of one or two drops of dilute sulphuric acid, add an equal volume of solution of hydrogen peroxide, and pour a layer of benzene on the mixed liquids; then add one or two drops of a solution of potassium chromate or dichromate and shake well; the benzene layer acquires a bluish-violet colouration, while the aqueous layer remains yellow. Pilocarpine nitrate is stated to contain varying amounts of *isopilocarpine* nitrate, which lowers the melting-point; the chemically pure salt melts at 177° to 178°.

Soluble in water (1 in 8), alcohol (90 per cent.) (1 in 50); almost insoluble in chloroform and ether.

Standard, B.P.—Pilocarpine nitrate has a melting-point of 174° to 178°. Specific rotation of a 10 per cent. w/v aqueous solution, +77° to +83°. Ash, not more than 0·1 per cent. It complies also with tests for the absence of certain other alkaloids and with a limit test for readily carbonisable substances.

Action and Uses.—The general action of pilocarpine is to stimulate the parasympathetic nerve endings of plain muscle, the heart and secretory glands. Its action is therefore a peripheral one, and any effect on the central nervous system is insignificant. Pilocarpine is a powerful sudorific, and was formerly much employed in various conditions in which excess of fluid accumulates in the body, notably in renal œdema and in uræmia. Owing to its depressant action on the heart it is now rarely used. The drug also causes augmented secretion from the salivary, gastric, pancreatic and intestinal glands, also from the mucous glands of the mouth, nose and respiratory tract, the main increase being in the water content. Milk, bile and urine are uninfluenced. It stimulates the motor nerve endings of the plain muscle of the gut and produces nausea, vomiting and diarrhœa. Pilocarpine decreases the frequency of the heart, contracts the bronchioles, and by its action on the spleen produces a leucocytosis.

In ophthalmic surgery, pilocarpine has been used as a substitute for physostigmine to contract the pupil and decrease the intra-ocular tension in glaucoma and detachment of the retina, but it is only about

half as active. For this purpose a 2 per cent. w/v solution may be employed, or a gelatin lamella containing 0.00025 gramme ($\frac{1}{4000}$ grain) may be placed in the conjunctival sac. Its action on the eye is less complete and of shorter duration than that of physostigmine, and a slight increase of tension may occur at first. Pilocarpine has been given by the mouth to relax the cardiac sphincter in cases of cardiospasm. The action of pilocarpine is in all cases antagonised by atropine, but in cases of atropine poisoning the use of pilocarpine is quite unjustifiable, for the reason that pilocarpine in no way antagonises the dangerous action of atropine on the brain. Pilocarpine nitrate is best **administered** by hypodermic injection in doses of from 0.006 to 0.016 gramme ($\frac{1}{160}$ to $\frac{1}{4}$ grain). Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The containers must comply with the limit of alkalinity of glass, and the solutions should be stored protected from light. Pills may be prepared with lactose and dextrose. Larger initial doses than 0.003 gramme ($\frac{1}{30}$ grain) by the mouth are not well tolerated. It has been recommended for use in lotions (1 in 250) to promote the growth of the hair, its effect being attributed to stimulation of the glands of the scalp. In cases of **poisoning** by pilocarpine, the stomach should be emptied and atropine given hypodermically.

Dose.—0.003 to 0.012 gramme ($\frac{1}{30}$ to $\frac{1}{8}$ grain).

Preparation

Guttæ Pilocarpinæ, B.P.C.—(Gutt. Pilocarp.)—Pilocarpine Eye Drops. Pilocarpine nitrate, 0.5 per cent. w/v, in sterilised water.

PIMENTA

(Piment.)

Pimento

Synonyms—Allspice; Jamaica Pepper.

Pimento consists of the dried, full-grown but unripe fruits of *Pimenta officinalis* Lindl. (Fam. Myrtaceæ), a tree indigenous to the West Indies, and cultivated in Jamaica and other islands.

The fruits are nearly globular berries, about 5 to 8 millimetres in diameter, dark reddish-brown, with a rough, brittle pericarp, crowned with the remains of the calyx surrounding the short style. The fruit is two-celled, each cell containing a single, brownish-black, reniform seed. The odour and taste are aromatic, having some resemblance to those of clove. The liquid obtained by boiling a few of the fruits with dilute hydrochloric acid, and filtering, gives not more than a faint bluish-green tint when treated with potassium ferrocyanide solution.

The diagnostic **microscopical** characters are the one-celled, conical, thick-walled hairs and small polygonal cells, having a rather

thick cuticle, from the epidermis; the numerous oil glands situated in the parenchyma immediately beneath the epidermis; the abundant, lignified, sclerenchymatous cells from the pericarp; the polygonal cells from the cotyledons, containing starch, mostly in compound grains, individual grains being muller-shaped.

Pimento **contains** from 3 to 4.5 per cent. of volatile oil containing about 70 per cent. of eugenol. Other constituents are small amounts of eugenolmethylether, cineole, *l*- α -phellandrene and caryophyllene.

Substitutes.—Fruits which have been collected when ripe or very nearly ripe become almost black on drying; they are sometimes made more attractive by colouring them with bole or brown ochre.

Standard.—Pimento yields not more than 6 per cent. of ash.

Pimento, in powder (*Pulvis Pimentæ* : *Pulv. Piment.*), contains the constituents and possesses the diagnostic microscopical characters of *Pimenta*, and complies with the standard for the unground drug.

Action and Uses.—Pimento is an aromatic stimulant and carminative resembling clove in its action. It is used principally for the production of *Oleum Pimentæ*, in which form it is generally employed in medicine.

Preparation

Aqua Pimentæ Concentrata, B.P.C.—(*Aq. Piment. Conc.*)—Concentrated Pimento Water. Oil of Pimento, 1 in 50. When pimento water (*Aqua Pimentæ*) is ordered, this preparation diluted with 39 times its volume of distilled water may be dispensed. Dose.—0.3 to 1 millilitre (5 to 15 minims).

PINUS ALBA

(*Pinus Alb.*)

White Pine

Synonym—White Pine Bark.

White pine is the bark of the Weymouth pine, *Pinus Strobus* Linn. (Fam. Pinacæ), deprived of the cork and part of the cortex, and dried. The Weymouth pine grows throughout the North-Eastern United States of America and in Canada.

The bark occurs in flat pieces, about 30 centimetres long, 15 centimetres wide and 1 to 3 millimetres thick; the longer pieces, which may be up to 80 centimetres long, are often folded. The outer surface is pinkish-yellow to brown, coarsely striated, with a few small patches of grey-brown periderm, and numerous small cavities containing oleo-resin; the inner surface is yellowish-brown, finely striated longitudinally and transversely corrugated. The bark is tough and the fracture very fibrous. The odour is slight and terebinthinate, and the taste sweetish, bitter and astringent.

White pine **contains** volatile oil, tannin, mucilage and resin.

Action and Uses.—White pine is used in conjunction with other medicaments as an ingredient of cough syrups.

Preparations

Extractum Pini Albi Liquidum, B.P.C.—(Ext. Pini Alb. Liq.)—Liquid Extract of White Pine. 1 in 1. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Syrupus Pini Albi Compositus, B.P.C.—(Syr. Pini Alb. Co.)—Compound Syrup of White Pine. Liquid extract of white pine, 1 in 20, and syrup of tar, 1 in 5, with liquid extract of squill, solution of bordeaux B, ammonium chloride, sucrose, glycerin and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

PINUS CANADENSIS

(*Pinus Canad.*)

Hemlock Spruce

Synonyms—Pinus Bark; Hemlock Spruce Bark.

Hemlock spruce is the dried inner bark of the trunk and branches of *Tsuga canadensis* Carr (Fam. Pinaceæ), a large tree indigenous to Eastern North America.

The bark occurs in flattened pieces of varying size, about 5 millimetres thick, the outer surface being coarsely striated longitudinally, cinnamon-brown or dark brown, with occasional patches of the purplish-pink rhytidome and dark grey cork. When the outer bark is present, it is brownish-grey in colour, longitudinally wrinkled, and marked with reddish-brown transverse lenticels. The inner surface is striated and yellowish-brown, with numerous small glistening points. The fracture is fibrous. The smoothed, transverse section viewed under a lens shows here and there externally a thin, pinkish-purple line, the rhytidome, within which is the cinnamon-brown secondary phloem with numerous paler, scattered groups of sclerenchymatous cells. The odour is slight, and the taste strongly astringent.

Hemlock spruce **contains** from 8 to 15 per cent. of tannin, but the bark also contains a little resin and volatile oil. The tannin appears to be identical with that of oak bark, and an extract of the bark is used in tanning. A substance resembling Burgundy pitch exudes from the trunk and hardens on the bark; it is known as hemlock pitch or Canada pitch, and has rubefacient properties similar to those of Burgundy pitch; it is separated from the bark by boiling with water, and consists of resin with a trace of volatile oil. Hemlock spruce, or spruce needle, oil contains *l*-pinene, *l*-bornyl acetate and sesquiterpenes. The ash of hemlock spruce is about 2 per cent.; it yields to alcohol (45 per cent.) about 15 per cent. of extractive.

Action and Uses.—Hemlock spruce is used as an astringent in catarrhal diseases of the mucous membrane. The liquid extract,

diluted 1 in 10 of water, has been employed as an injection in the treatment of leucorrhœa and gonorrhœa, and is given internally for diarrhœa.

Preparation

Extractum Pini Canadensis Liquidum, B.P.C.—(Ext. Pini Canad. Liq.)—
Liquid Extract of Hemlock Spruce. 1 in 1. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

PIPER NIGRUM

(Piper Nig.)

Black Pepper

Synonym—Piper.

Black pepper consists of the dried, unripe fruits of *Piper nigrum* Linn. (Fam. Piperacæ), a climbing plant indigenous to South India, and cultivated there as well as in the islands of the Malay Archipelago, the Malay Peninsula, Siam, etc.

The fruits are subspherical, dark brown, superior, and about 3.5 to 6 millimetres in diameter. The surface is deeply and coarsely reticulately wrinkled; at the apex the remains of a sessile stigma is visible. The odour is aromatic and the taste pungent. A vertical section of the fruit shows a thin, narrow, dark pericarp, within which is the whitish kernel of the single seed, to which the pericarp firmly adheres. The kernel consists almost entirely of perisperm, which is hollow at the centre, and surrounds at its apex the scanty endosperm in which the minute embryo is embedded.

The diagnostic **microscopical** characters are the tabular epidermal cells containing small rectangular crystals about 6 to 10 microns long; the hypodermis of thin-walled parenchyma containing numerous groups of rectangular or polygonal stone cells with rather large lumina; the inner pericarpic sclerenchyma consisting of a single layer of brown, lignified beaker cells; the reddish-brown seed coat, usually with the hyaline layer attached; the abundant starch, mostly in large polyhedral masses, individual grains being angular and up to 7 microns in diameter; the oil cells of the perisperm and pericarp.

Black pepper **contains** 5 to 9 per cent. of a colourless, crystalline alkaloid, piperine, 1.0 to 2.5 per cent. of a volatile oil (specific gravity, 0.890 to 0.900; refractive index at 20°, 1.4935 to 1.4977; optical rotation, -2.7° to -4.6° ; consisting almost entirely of sesquiterpenes), and about 6 per cent. of a pungent, green resin, chavicine, isomeric with piperine. Piperidine is stated to be invariably a constituent of pepper, probably derived from the decomposition of the piperine. It contains also about 30 per cent. of starch and yields about 6 per cent. of non-volatile ether extractive.

Varieties.—There are several varieties of black pepper distinguished by the names of their places of origin. The more usual are Trang, Tellicheri, Saigon, Lampong and Acheen. They differ somewhat in appearance, varying from greyish-brown to brownish-black in colour according to the methods used in drying, some varieties being smoked in kilns while others are dried without artificial heat.

Standard.—Black pepper contains not more than 2 per cent. of foreign organic matter. Ash, not more than 6 per cent. Acid-insoluble ash, not more than 1 per cent.

Black pepper, in powder (*Pulvis Piperis Nigri* : *Pulv. Piper. Nig.*), contains the constituents and possesses the diagnostic microscopical characters of *Piper Nigrum*, and complies with the limits for ash and acid-insoluble ash of the unground drug.

Action and Uses.—Black pepper possesses in a high degree the stimulating and carminative properties of the volatile oils, causing a reflex flow of saliva, with increased secretion of gastric juice and improved appetite. Gastro-intestinal movements are augmented, with consequent eructation of gas and relief of colic. In sufficient doses, the peppers dilate the superficial vessels of the skin, causing a feeling of warmth, followed by diaphoresis and some reduction of temperature. On account of these properties they are much employed as condiments, especially in hot countries. Black pepper is a diuretic, and is sometimes used in place of cubeb in gonorrhœa and urethritis, but is apt to irritate. It is **administered** as *Confectio Piperis*, often with confection of senna. In conjunction with opium and other carminatives it is employed as *Pulvis Opii Compositus*.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

PIPER ALBUM.—White pepper is the fruit of *P. nigrum*, but is composed of the ripe fruits which have been deprived of their outer coating by soaking in water and rubbing, and then dried in the sun. It contains less volatile oil and, compared with black pepper, is lacking in aroma. The commoner commercial varieties are known as Java, Siam, Saigon, Montok, Singapore and Penang. Powdered white pepper may be made by grinding the white pepper or by treating black pepper in special machines which remove the pericarp, the inner portion or perisperm alone being ground to powder. The latter gives a product of superior aroma.

PIPER LONGUM.—Long pepper is the dried, unripe fructification of *Piper Chaba* Hunter (Fam. Piperaceæ), a plant indigenous to the Malay Archipelago. The fructification consists of a dense spike about 3·5 centimetres long and 0·5 centimetre in diameter. The taste and odour are like those of black pepper, but not so strong. It contains about 1 per cent. of volatile oil and about 5 per cent. of piperine, a pungent resin (chavicine) and starch. Long pepper has been employed as a stimulant and carminative, its properties residing principally in the volatile oil and resin. For medicinal preparations black pepper is usually preferred. **Dose.**—0·3 to 0·6 gramme (5 to 10 grains).

Preparations

Confectio Piperis, B.P.C.—(Conf. Piper.)—Confection of Pepper. Black pepper, 1 in 10, with caraway and purified honey. **Dose.**—4 to 8 grammes (1 to 2 drachms).

This confection was included in the British Pharmacopœia, 1914.

Pilulæ Asiaticæ, B.P.C.—(Pil. Asiatic.)—Asiatic Pills. Each pill contains $\frac{1}{2}$ grain of arsenic trioxide and $\frac{3}{4}$ grain of black pepper. **Dose.**—1 pill.

PIPERAZINA

(Piperaz.)

Piperazine*Synonym*—Piperazine Hydrate.

Piperazine is the hydrate of a heterocyclic base which may be prepared by the action of ammonia on ethylene dibromide. It occurs in the form of colourless, glassy, lustrous, deliquescent tablets, absorbing carbon dioxide from the air and forming the carbonate, and having a strongly alkaline reaction, a saline taste, and a faint but characteristic odour. Anhydrous piperazine, $\text{C}_4\text{H}_{10}\text{N}_2$, melts between 108° and 110° .

Readily **soluble** in water, somewhat less so in alcohol; its aqueous solution readily decomposes.

Standard.—Piperazine melts between 43° and 44° . Ash, not more than 0.1 per cent. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates.

Action and Uses.—Piperazine has been used for gout and rheumatism, on the supposition that it would prevent or remove deposits of uric acid in the system by forming soluble urates which would be eliminated in the urine. It is, however, extremely doubtful whether any such solvent action is exerted in the body. It may be **administered** as Piperazina Effervescens. Piperazine is incompatible with acetanilide, alkaloidal salts, spirit of nitrous ether, sodium salicylate and salts of iron and mercury.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparation

Piperazina Effervescens, B.P.C.—(Piperaz. Efferv.)—Effervescent Piperazine. About 1 in 12. Dose.—4 to 12 grammes (1 to 3 drachms).

PISCIDIA

(Piscid.)

Piscidia*Synonym*—Jamaica Dogwood.

Piscidia is the root-bark of *Piscidia Erythrina* Linn. (Fam. Leguminosæ), a shrub found in tropical America and the West Indies, where it is used as a fish poison.

The root-bark occurs in quills or curved pieces, 5 to 15 centimetres or up to 1 metre in length, 2 to 8 centimetres broad and 4 to 6 millimetres thick. The outer surface is orange-brown where the cork is present, and dark greyish-brown where the cork is exfoliated; it

is wrinkled, with thin projecting edges of exfoliating scales of the outer cork, and somewhat fissured. Where the surface is scraped the exposed phloem is greenish-black. Older pieces are dull reddish-brown, with reddish, corky warts and transverse fissures at intervals. The inner surface is brownish, smooth and finely chequered. The fracture is short and even in the outer part, somewhat splintery internally. The odour is characteristic, and the taste somewhat acid.

Piscidia **contains** resin, fat, a crystallisable substance named piscidin, and a bitter glycoside which is soluble in water.

Action and Uses.—*Piscidia* exerts a sedative action, and is employed to reduce sensibility to pain. In the form of liquid extract it is used in the treatment of dysmenorrhœa. It has also been employed to induce sleep, and to relieve the pain of toothache, neuralgia, etc.

Preparation

Extractum Piscidiæ Liquidum, B.P.C.—(Ext. Piscid. Liq.)—Liquid Extract of *Piscidia*. 1 in 1. Dose.—2 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

PITUITARIUM

(Pituit.)

Pituitary

Synonyms—Dry Pituitary Gland; Dry Pituitary; Desiccated Pituitary.

Pituitary consists of the cleaned and dried pituitary bodies or glands obtained from oxen or other mammals. The pituitary gland or hypophysis is situated below the brain in a depression (sella turcica) in the bony case which encloses the brain. It consists of two main parts; (1) a stalk, or infundibulum, which descends from the part of the brain known as the tuber cinereum, this portion of the gland being called the posterior lobe [pituitary (posterior lobe)]; (2) a portion about four times larger, which enfolds the posterior lobe in front, below and at the sides, this portion being known as the anterior lobe [pituitary (anterior lobe)]. The two lobes are separated by a narrow strip of tissue known as the pars intermedia. In order to avoid confusion it is necessary, therefore, to distinguish between the three products—pituitary, pituitary (anterior lobe) and pituitary (posterior lobe). The fresh gland yields about one-fifth of its weight of pituitary. Pituitary occurs as a yellowish or greyish, amorphous powder, having a characteristic odour. It is only partly **soluble** in water.

Action and Uses.—Pituitary, pituitary (anterior lobe) and pituitary (posterior lobe) are used in medicine for oral administration, but there is no generally accepted experimental or clinical evidence of their value. They are **administered** in capsules or tablets in doses of 0.03 to 0.3 gramme ($\frac{1}{2}$ to 5 grains) of desiccated gland, 0.03 to 0.3 gramme

($\frac{1}{2}$ to 5 grains) of anterior lobe and 0.003 to 0.03 gramme ($\frac{1}{20}$ to $\frac{1}{2}$ grain) of posterior lobe. Pituitary and posterior pituitary are given in certain forms of obesity, and for low blood pressure and intestinal stasis; anterior pituitary is given, often with thyroid, to promote the growth of backward children. Both the anterior and posterior lobes, however, contain active principles which are readily extracted and possess striking physiological properties (see *Extractum Pituitarii Liquidum*). Desiccated pituitary (posterior lobe) powder is occasionally employed as a snuff in doses of 0.04 gramme ($\frac{3}{8}$ grain) in the treatment of diabetes insipidus. Dry pituitary (posterior lobe) powder is also used as a laboratory standard in the biological assay of pituitary (posterior lobe) extract; for this purpose the posterior lobe of fresh pituitary gland of oxen is extracted with acetone, dried, and assayed by comparison with a standard preparation kept in the National Institute for Medical Research, London.

PIX BURGUNDICA

(Pix Burgund.)

Burgundy Pitch

Burgundy pitch is a resinous exudation obtained from the stem of *Picea excelsa* Link (Fam. Pinacæ) and purified by melting and straining. It is obtained from Finland and the Black Forest. Incisions are made in the bark, and the exuding oleo-resin is scraped out of the holes in which it has solidified; it is then melted under water and strained. It is an opaque, hard, brittle, reddish or yellowish-brown substance, which gradually assumes the form of the vessel in which it is kept. It breaks with a clean, conchoidal fracture. The odour is aromatic, and the taste sweet and aromatic.

Burgundy pitch **contains** a little volatile oil and resin; the latter appears to consist of α - and β -piceapimarolic acids with small quantities of piceapimarinic and piceapimaric acids, and a resene (juroresene). A factitious Burgundy pitch is prepared by melting together common pitch, colophony and turpentine, and agitating the mixture with water. Its odour differs from that of the genuine substance, and it does not form a clear solution with glacial acetic acid.

Soluble in twice its weight of glacial acetic acid; readily soluble in alcohol.

Action and Uses.—Burgundy pitch is a mild counter-irritant, and is employed in the preparation of plasters. *Emplastrum Picis* is used in chronic bronchitis, rheumatism and lumbago.

Preparation

Emplastrum Picis, B.P.C.—(Emp. Pic.)—Plaster of Pitch. *Syn.*—Poor Man's Plaster. Burgundy pitch, about 1 in 2, with olibanum, colophony, yellow beeswax, olive oil and distilled water.

PIX CARBONIS**(Pix Carbon.)****Coal Tar**

Coal tar is a product obtained by the destructive distillation of bituminous coal at about 1000°. It occurs as a thick, nearly black, viscid liquid, with a strong, penetrating, characteristic odour. The alkalinity of its aqueous solutions serves to distinguish coal tar from tar obtained from wood or lignite, or by the destructive distillation of bituminous coal at temperatures below 600°. The surface of water in contact with coal tar shows by reflected light a blue, metallic lustre. Specific gravity, about 1.15. On exposure to the air, it gradually becomes hardened. It burns on ignition with a luminous, sooty flame.

The chief **constituents** of coal tar are benzene, C_6H_6 , and its homologues, isolated by fractional distillation from the light oil (boiling-point below 170°); phenol, cresols and naphthalene, $C_{10}H_8$, from the middle (or carbolic) oil (boiling-point, 170° to 230°); cresols and their homologues from the heavy oil (boiling-point, 230° to 270°); anthracene, $C_{14}H_{10}$, from the green oil (boiling-point, 270° to 400°); the residue is pitch. The tar also contains small quantities of basic compounds such as aniline, pyridine, acridine, carbazole, etc., and sulphur compounds such as thiophene, C_4H_4S .

Slightly **soluble** in water; partially soluble in alcohol, ether, chloroform, benzene and volatile oils.

Standard.—Coal tar leaves not more than 2 per cent. of ash. Water shaken with coal tar acquires an alkaline reaction.

Action and Uses.—Coal tar has antiseptic, stimulating and antipruritic properties, and is employed for application to the skin in pruritus, psoriasis, eczema and other skin affections. Prepared coal tar is used for the same purposes, but by some is considered to be less efficacious than the crude coal tar. Liquor Picis Carbonis is used in lotions and ointments, but should not be used when there is inflammation of the skin.

Preparations

Liquor Picis Carbonis, B.P.—(Liq. Pic. Carbon.)—Solution of Coal Tar. It is prepared by macerating prepared coal tar, 20 per cent. w/v, and quillaia in alcohol (90 per cent.) or in industrial methylated spirit, suitably diluted

Lotio Picis Carbonis Alkalina, B.P.C.—(Lot. Pic. Carbon. Alk.)—Alkaline Lotion of Coal Tar. Solution of coal tar, about 1 in 50, and sodium bicarbonate, in distilled water.

Lotio Picis Carbonis et Plumbi, B.P.C.—(Lot. Pic. Carbon. et Plumb.)—Coal Tar and Lead Lotion. Solution of coal tar and strong solution of lead subacetate, of each about 1 in 30, in distilled water.

Pasta Picis Carbonis, B.P.C.—(Past. Pic. Carbon.)—Coal Tar Paste. Coal tar, about 3.5 per cent., with compound paste of zinc oxide.

Pix Carbonis Præparata, B.P.—(Pix Carb. Præp.)—Prepared Coal Tar. Coal tar deprived of its more volatile constituents by heating at 50°.

Unguentum Picis Carbonis, B.P.C.—(Ung. Pic. Carbon.)—Coal Tar Ointment. Solution of coal tar, about 6·25 per cent., in yellow soft paraffin.

Unguentum Picis Carbonis Compositum, B.P.C.—(Ung. Pic. Carbon. Co.)—Compound Coal Tar Ointment. Solution of coal tar, about 6·25 per cent., and ammoniated mercury, about 3 per cent., in yellow soft paraffin.

PIX LIQUIDA

(Pix Liq.)

Tar

Synonym—Stockholm Tar.

Tar is the bituminous liquid obtained by the destructive distillation of the wood of the Scotch fir, *Pinus sylvestris* Linn., and other members of the Family, Pinaceæ. It occurs as a dark brown or blackish, semi-liquid substance, with a strong, characteristic, empyreumatic odour, and a bitter, pungent, empyreumatic taste. It has a specific gravity of about 1·020 to 1·150. It is transparent in thin layers if free from water. When stored for some time, it separates into an under layer of granular character, due to minute crystallisation of catechol, resin acids, etc., and a surface layer of a syrupy consistence. Tar has an acid reaction which is imparted to water when shaken with it, and it may thereby be distinguished from coal tar, which has an alkaline reaction. When water is shaken with tar, filtered, if necessary through diatomite, and treated with one or two drops of 1 in 1000 solution of ferric chloride, a red colour is produced; under similar conditions, birch tar gives a green colouration. Tar may be distinguished from beech tar by shaking a light petroleum extract with dilute copper acetate solution; the light petroleum layer is coloured green.

Soluble in alcohol (90 per cent.) (1 in 10), ether, chloroform, fixed and volatile oils, glacial acetic acid and dilute solutions of alkali hydroxides; almost insoluble in water.

Standard, B.P.—Tar is the wood tar known in commerce as Stockholm tar.

Action and Uses.—Tar has antiseptic properties and is given as an expectorant in chronic bronchitis and to relieve the cough of phthisis; it is also mixed with hot water and the vapour inhaled for the same purpose. Tar is **administered** as Syrupus Picis Liquidæ, often with syrup of codeine phosphate. It may also be given in gelatin capsules or in pills. **Externally**, tar is employed in chronic skin diseases, especially in psoriasis and eczema. Its action in allaying pruritus is not so marked as that of coal tar. It may be used as Unguentum Picis Liquidæ, which may be reduced in strength and softened, if required, by the addition of olive oil or lard.

Dose.—0·12 to 0·6 gramme (2 to 10 grains).

Preparations

Syrupus Pini Albi Compositus, B.P.C.—(Syr. Pini Alb. Co.)—Compound Syrup of White Pine. Liquid extract of white pine, 1 in 20, and syrup of tar, 1 in 5, with liquid extract of squill, solution of bordeaux B, ammonium chloride, sucrose, glycerin and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Syrupus Picis Liquidæ, B.P.C.—(Syr. Pic. Liq.)—Syrup of Tar. Tar, 0.5 per cent. w/v, with alcohol (90 per cent.), sucrose and distilled water. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Unguentum Picis Liquidæ, B.P.C.—(Ung. Pic. Liq.)—Tar Ointment. Tar, 70 per cent., in lard and yellow beeswax.

This ointment was included in the British Pharmacopœia, 1914.

Unguentum Sulphuris Compositum, B.P.C.—(Ung. Sulphur. Co.)—Compound Sulphur Ointment. Sublimed sulphur and tar, of each, 15 per cent., and calcium carbonate, 10 per cent., in lard and soft soap.

PLUMBI ACETAS

(Plumb. Acet.)

Lead Acetate

Synonym—Sugar of Lead.

Lead acetate, $(\text{CH}_3\cdot\text{COO})_2\text{Pb} \cdot 3\text{H}_2\text{O}$, may be prepared by dissolving finely divided lead monoxide in hot acetic acid, filtering the solution while hot and allowing it to crystallise. It occurs in the form of small, white, transparent, monoclinic prisms or heavy, crystalline masses, having a faint, acetous odour and a sweet, astringent taste. It is efflorescent in warm air, and absorbs carbon dioxide on exposure, then forming with water an opalescent solution. It becomes anhydrous when dried at 40° . If heated rapidly to 75° it melts in its water of crystallisation, and at a higher temperature it is converted into a basic salt which fuses at about 280° with continued loss of acetic acid, finally undergoing complete decomposition with evolution of acetone and carbon dioxide, leaving a residue of finely divided metallic lead mixed with oxide and carbonate. It forms a clear, slightly acid solution with water free from carbon dioxide.

Soluble in water (1 in 2.5), alcohol (90 per cent.) (1 in 30), glycerin (1 in 2).

Standard, B.P.—Lead acetate contains not less than 99.5 per cent. and not more than the equivalent of 104.5 per cent. of $\text{C}_4\text{H}_6\text{O}_4\text{Pb} \cdot 3\text{H}_2\text{O}$. It complies with a test for solubility in water, with a test for the absence of copper, iron, zinc and silver, and with a limit test for chloride.

Action and Uses.—Lead salts are used in medicine chiefly for their protective and astringent action, either on the skin, or on the vaginal, urethral, and rectal mucous membranes in inflammatory conditions, or,

when taken internally, to arrest diarrhœa. In all cases their astringent action is due to the formation of lead albuminate, which, in contact with mucous membranes, forms a protective coating and prevents further penetration of the metal. On account of the formation of insoluble lead albuminate, salts of lead taken internally are absorbed with extreme slowness; nevertheless, owing to still slower excretion, cumulation may occur, and lead poisoning frequently results from the ingestion of lead in small quantities over a prolonged period. The symptoms of plumbism are anæmia and severe abdominal colic, accompanied by obstinate constipation and often by vomiting. Examination of the gums shows a blue line on the free border, due to a deposit of lead sulphide. There may also be paralyses, of which paralysis of the extensor muscles of the fore-arm is much the commonest. Epileptiform convulsions, optic neuritis, retinitis and contracted granular kidneys are other conditions which may be caused by chronic lead poisoning. Lead has a specific action on all muscular tissue; it excites automatic contractions in plain muscle fibres, the effect on the intestinal walls being to produce lead colic, and on the uterus to cause menorrhagia, or, if pregnant, to expel its contents. Striped muscle under the action of lead is easily exhausted and fails to respond to stimulation, subsequently undergoing degeneration. Lead diminishes the excretion of uric acid and is regarded as a predisposing cause of gout.

Internally, lead acetate is employed in diarrhœa, dysentery, cholera, hæmoptysis and in intestinal ulcerations of tubercular or typhoid origin. It is **administered** in pills and tablets. **Externally**, it is sometimes used for vaginal and urethral injections (1 in 250). Glycerinum Plumbi Subacetatis, diluted with paraffin ointment, or with 4 to 6 parts of glycerin, forms an emollient and healing application in eczema and chronic ulcerations. Lotions (1 part to 8 parts of water) are used in pruritus ani and (1 part to 40 parts of water) as vaginal injections. Liquor Plumbi Subacetatis Dilutus and Lotio Plumbi Evaporans are employed largely in soothing and astringent lotions for burns and bruises. Unguentum Plumbi Acetatis and Unguentum Plumbi Subacetatis are used in pruritus ani, as astringent applications for piles, and for inflammatory conditions of the skin and mucous membranes. Suppositorium Plumbi cum Opio soothes the pain and arrests the bleeding of hæmorrhoids. Solutions of lead subacetate are not suitable for use in eye lotions. Lead acetate is **incompatible** with carbonates, chlorides, iodides, sulphates, phosphates and tannic acid.

The treatment of chronic lead **poisoning** should be preventive as well as curative (see Calcii Chloridum). Drinks containing sulphuric acid form insoluble lead sulphate, and potassium iodide aids in the excretion of lead from the system, but it should not be forgotten that it is possible for sufficient lead sulphate to be absorbed to cause poisonous effects. In order to render lead salts insoluble when accidentally swallowed, milk and white of egg should be given, and a purgative dose of magnesium sulphate or sodium sulphate should follow.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Glycerinum Plumbi Subacetatis, B.P.C.—(Glycer. Plumb. Subacet.)—Glycerin of Lead Subacetate. A glycerin solution of the residue obtained by evaporating strong solution of lead subacetate.

This glycerin was included in the British Pharmacopœia, 1914.

Liquor Plumbi Subacetatis Dilutus, B.P.—(Liq. Plumb. Subacet. Dil.)—Dilute Solution of Lead Subacetate. *Syn.*—Liquor Plumbi Subacetatis; Goulard's Lotion; Goulard Water; Lotio Plumbi; Lead Lotion; Liquor Plumbi. Strong solution of lead subacetate, 1 in 80, in distilled water. It should be freshly prepared.

Liquor Plumbi Subacetatis Fortis, B.P.—(Liq. Plumb. Subacet. Fort.)—Strong Solution of Lead Subacetate. *Syn.*—Goulard's Extract; Liquor Plumbi Fortis. It contains not less than 19 per cent. and not more than 21·5 per cent. w/w of total Pb, and has an alkalinity corresponding to not less than 10·2 per cent. and not more than 11·6 per cent. w/w of PbO. It should be stored in well-filled, well-closed containers.

Lotio Picis Carbonis et Plumbi, B.P.C.—(Lot. Pic. Carbon. et Plumb.)—Coal Tar and Lead Lotion. Solution of coal tar and strong solution of lead subacetate, of each about 1 in 30, in distilled water.

Lotio Plumbi cum Opio, B.P.C.—(Lot. Plumb. c. Opio)—Lead and Opium Lotion. Tincture of opium, 1 in 20, in dilute solution of lead subacetate.

Lotio Plumbi Evaporans, B.P.C.—(Lot. Plumb. Evap.)—Evaporating Lead Lotion. Strong solution of lead subacetate, 1 in 80, and alcohol (90 per cent.), 1 in 5, in distilled water.

Pilulæ Plumbi cum Opio, B.P.C.—(Pil. Plumb. c. Opio)—Lead Pills with Opium. Each pill contains 1½ grains of lead acetate and about ¼ grain of powdered opium. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopœia, 1914, under the name of Pilula Plumbi cum Opio.

Suppositorium Plumbi cum Opio, B.P.—(Supp. Plumb. c. Opio)—Suppository of Lead with Opium. *Syn.*—Suppositorium Plumbi Compositum. Each suppository contains 0·2 gramme (3 grains) of lead acetate and 0·06 gramme (1 grain) of powdered opium, equivalent to about 0·006 gramme ($\frac{1}{16}$ grain) of anhydrous morphine.

Tabellæ Plumbi cum Opio, B.P.C.—(Tab. Plumb. c. Opio)—Tablets of Lead with Opium. Each tablet contains 3 grains of lead acetate, ¼ grain of powdered opium, and sucrose. Dose.—1 tablet.

Unguentum Glycerini Plumbi Subacetatis, B.P.C.—(Ung. Glycer. Plumb. Subacet.)—Glycerin of Lead Subacetate Ointment. Glycerin of lead subacetate, about 16·5 per cent. w/w, in white paraffin ointment.

Unguentum Hydrargyri Plumbi et Zinci, B.P.C.—(Ung. Hydrarg. Plumb. et Zinc.)—Mercury, Lead and Zinc Ointment. *Syn.*—Unguentum Metallorum. Ointment of mercuric nitrate, ointment of lead subacetate and ointment of zinc oxide, equal parts.

Unguentum Plumbi Acetatis, B.P.C.—(Ung. Plumb. Acet.)—Lead Acetate Ointment. Lead acetate, 4 per cent., in white paraffin ointment.

Unguentum Plumbi Subacetatis, B.P.C.—(Ung. Plumb. Subacet.)—Lead Subacetate Ointment. Strong solution of lead subacetate, 12·5 per cent. w/w, in wool fat and hard and soft paraffins.

This ointment was included in the British Pharmacopœia, 1914.

PLUMBI CARBONAS

(Plumb. Carb.)

Lead Carbonate*Synonyms*—White Lead; Cirussa.

Lead carbonate is a basic lead carbonate closely approximating in composition to the formula, $2\text{PbCO}_3, \text{Pb(OH)}_2$, and may be prepared by interaction of basic lead acetate and carbon dioxide. It occurs as a white, odourless, tasteless, heavy, non-gritty, amorphous powder, or as a white, easily pulverisable mass. The solution in nitric acid is precipitated by sodium hydroxide, the precipitate being soluble in excess of the alkali. When heated to 155° , the carbonate loses the elements of water, at 180° it loses carbon dioxide and turns yellow, and on charcoal in the blow-pipe flame it yields globules of metallic lead surrounded by a reddish-yellow incrustation. The normal carbonate, PbCO_3 , is obtained by precipitation from a solution of a lead salt with ammonium carbonate.

Insoluble in water and alcohol.

Standard.—Lead carbonate, determined by the method of the British Pharmacopœia for Plumbi Monoxidum, contains not less than 79 per cent. of Pb; each millilitre of N/10 potassium permanganate is equivalent to 0.01036 gramme of Pb. The residue obtained on dissolving 1 gramme in 2 millilitres of nitric acid and 4 millilitres of water is not more than 1 per cent. (limit of insoluble matter). Dissolve 0.5 gramme in 4 millilitres of acetic acid, add 50 millilitres of water, completely precipitate the lead with hydrogen sulphide and filter; the residue obtained on evaporating the filtrate and igniting is not more than 0.01 gramme (limit of alkaline earths and alkalis).

Action and Uses.—Lead carbonate is used in the form of ointment as a mildly astringent and soothing application.

Preparation

Unguentum Plumbi Carbonatis, B.P.C.—(Ung. Plumb. Carb.)—Lead Carbonate Ointment. Lead carbonate, 10 per cent., in white paraffin ointment.

PLUMBI IODIDUM

(Plumb. Iod.)

Lead Iodide $\text{PbI}_2 = 461.1$

Lead iodide may be prepared by the interaction of a soluble lead salt and potassium iodide. It occurs in the form of thin, shining, golden-yellow scales, or as a bright lemon-yellow, heavy, odourless powder, which is tasteless or has only a slight metallic taste. Aqueous

solutions are neutral to litmus. When heated it becomes red, then black, and, if air is excluded, it fuses and volatilises; in contact with air it melts, giving off iodine and leaving a yellow, crystalline mass of basic lead iodide. It is decomposed by light with liberation of iodine, especially in the presence of moisture, and should be **stored** protected from light.

Soluble in water (about 1 in 2000), boiling water (about 1 in 200); soluble in solutions of ammonium chloride and potassium iodide; very slightly soluble in alcohol.

Standard.—Lead iodide contains not less than 95 per cent. of PbI_2 . 1 gramme warmed with 2 grammes of ammonium chloride and 15 millilitres of water forms a clear, colourless solution (limit of chromate and other insoluble foreign salts).

Assay.—Dissolve about 0.75 gramme, accurately weighed, in 45 millilitres of sodium hydroxide solution, using gentle heat if necessary; add 50 millilitres of N/10 silver nitrate, and acidify with dilute nitric acid; titrate with N/10 ammonium thiocyanate, using ferric ammonium sulphate solution as indicator; deduct the volume of N/10 silver nitrate required for the chloride present in 45 millilitres of the sodium hydroxide solution; each millilitre of N/10 silver nitrate is equivalent to 0.02305 gramme of PbI_2 .

Action and Uses.—Lead iodide has been used externally in the form of Unguentum Plumbi Iodidi as a mild counter-irritant for application to swollen glands, and for chronic joint enlargements. It was formerly given internally in doses of 0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains).

Preparation

Unguentum Plumbi Iodidi, B.P.C.—(Ung. Plumb. Iod.)—Lead Iodide Ointment Lead iodide, 10 per cent., in benzoinated lard.

This ointment was included in the British Pharmacopæia, 1914.

PLUMBI MONOXIDUM

(Plumb. Monox.)

Lead Monoxide

$PbO = 223.2$

Synonyms—Plumbi Oxidum; Lead Oxide; Litharge.

Lead monoxide may be obtained by heating lead in air. At a moderate heat the oxide is obtained in the form of a yellow or pale orange powder; at a higher temperature the oxide melts and, on cooling, forms a scaly mass which may become brick-red in colour. Lead monoxide is amphoteric. It is very slightly **soluble** in water; the presence of a small quantity of saline matter in the water lessens the solubility, but

the presence of organic matter, especially sugar, increases it; the slight solubility in water is accompanied by the formation of lead hydroxide, which is faintly alkaline. It is insoluble in alcohol, but soluble in acetic and dilute nitric acids with formation of salts, and in hot solutions of alkali hydroxides forming plumbites.

Standard, B.P.—Lead monoxide contains not less than 99 per cent. of PbO, calculated on the ignited substance. Loss on ignition, not more than 4 per cent.

Uses.—Lead monoxide is used in pharmacy principally in the preparation of *Emplastrum Plumbi*, and of the glycerin and aqueous solutions of lead subacetate.

PLUMBI OLEAS

(*Plumb. Oleas*)

Lead Oleate

Lead oleate may be prepared by warming 100 parts of oleic acid in a porcelain dish to about 60° to 65°, and adding a solution of 16 parts of sodium hydroxide dissolved in a mixture of 30 parts of alcohol and 90 parts of water, until the solution is only faintly alkaline to phenolphthalein. This soap is dissolved in about 2000 parts of water, and into it is poured, with constant stirring, a solution of 67 parts of lead acetate in about 800 parts of water. The resulting precipitate should settle rapidly, leaving a clear supernatant liquid. The precipitate is collected, well washed until all traces of the salt formed in the reaction have been removed, and dried by spreading on porous tiles or bibulous paper. It occurs as an unctuous, granular powder.

Soluble in alcohol, ether, oil of turpentine and benzene.

Action and Uses.—Lead oleate is soothing and mildly astringent when applied to inflamed and excoriated surfaces. For this purpose it is applied as *Unguentum Plumbi Oleatis*. *Emplastrum Plumbi*, spread on calico, is used to draw together the edges of wounds, and as a protective agent. Spread on chamois leather, it affords greater protection, and is used for corns, bunions and abraded surfaces.

Preparations

Emplastrum Plumbi, B.P.—(*Emp. Plumb.*)—Plaster of Lead. *Syn.*—Lead Plaster; Diachylon Plaster; Diachylon. It is prepared by boiling lead monoxide with olive oil and distilled water.

Unguentum Plumbi Oleatis, B.P.C.—(*Ung. Plumb. Oleat.*)—Lead Oleate Ointment. *Syn.*—Unguentum Diachylon; Diachylon Ointment; Hebra's Ointment. Plaster of lead, 50 per cent., with oil of lavender and olive oil.

PODOPHYLLI RESINA

(Podoph. Res.)

Resin of Podophyllum*Synonyms*—Podophyllum Resin; Podophyllin.

Resin of podophyllum is a mixture of resins obtained from podophyllum or from Indian podophyllum. It may be extracted by percolating with alcohol and pouring the concentrated percolate into water acidified with hydrochloric acid. The precipitated resin is well washed, and dried at a low temperature. The resin has an extremely irritating effect on the eyes and should be handled with care. It should be **stored** in well-closed containers and protected from light.

Resin of podophyllum occurs as a pale yellow or yellowish-brown, amorphous powder or in brownish-grey masses, having a characteristic odour and a bitter, acrid taste. It darkens in colour on exposure to light or when heated above 25°. The resin from podophyllum (*Podophyllum peltatum*) may be distinguished from that of Indian podophyllum (*P. emodi*) by gently shaking 0.5 millilitre of N/1 potassium hydroxide solution with 3 millilitres of a 13 per cent. w/v solution of the finely powdered resin in alcohol (60 per cent.); resin of podophyllum does not gelatinise, while resin of Indian podophyllum forms a stiff jelly.

Resin of podophyllum **contains** podophyllotoxin (varying from 20 per cent. in the case of resin from podophyllum, and at least 40 per cent. in resin from Indian podophyllum), podophylloresin, the yellow pigment, quercetin, and ill-defined resinous substances. Picropodophyllin is not naturally present in the resin, but is an isomeride of podophyllotoxin formed by the action of alkali upon the latter.

Soluble completely, or almost completely, in alcohol (90 per cent.); insoluble in cold water, partly soluble in hot water but precipitated again on cooling; partly soluble in ether, chloroform and dilute solution of ammonia.

Standard, B.P.—Resin of podophyllum loses, on drying at 100°, not more than 5 per cent. of its weight. Ash, not more than 1 per cent. Matter insoluble in dilute solution of ammonia, not more than 10 per cent. in the case of the resin from podophyllum, and not more than 50 per cent. in the case of the resin from Indian podophyllum.

Action and Uses.—Resin of podophyllum is a drastic but slowly acting purgative. Large doses may cause acute irritation of the stomach and intestines, with violent peristaltic contractions. It is employed in cases of habitual constipation associated with hepatic derangement. It is usually **administered** in pills with extract of hyoscyamus or belladonna to prevent griping, and is often given with nux vomica, aloes, colocynth, or rhubarb. Tinctura Podophylli may be given in mixture form with the tinctures of nux vomica and euonymus, the resin being suspended with a little mucilage of acacia, or it may be prescribed with aromatic spirit of ammonia, when the resin is held in solution.

Tinctura Podophylli Ammoniata has the advantage of miscibility with water without precipitation. Liquid preparations of podophyllum are, however, acrid and disagreeable.

Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Preparations

Pilulæ Aloini et Podophyllini Compositæ, B.P.C.—(Pil. Aloin. et Podoph. Co.)—Compound Aloin and Podophyllin Pills. Each pill contains $\frac{1}{4}$ grain each of aloin and jalap resin, $\frac{1}{16}$ grain of oleoresin of capsicum, $\frac{3}{8}$ grain each of the dry extracts of nux vomica and hyoscyamus, and about $\frac{1}{2}$ grain of resin of podophyllum. Dose.—1 to 4 pills.

Pilulæ Podophyllini, Belladonnæ et Nucis Vomicae, B.P.C.—(Pil. Podoph. Bellad. et Nuc. Vom.)—Podophyllin, Belladonna and Nux Vomica Pills. Each pill contains $\frac{1}{2}$ grain each of resin of podophyllum, dry extract of belladonna and dry extract of nux vomica, and 1 grain of aloes. Dose.—1 or 2 pills.

Pilulæ Podophyllini Compositæ, B.P.C.—(Pil. Podoph. Co.)—Compound Podophyllin Pills. Each pill contains $\frac{1}{2}$ grain of resin of podophyllum, 1 grain of mercurous chloride and $\frac{1}{2}$ grain of dry extract of belladonna. Dose.—1 pill.

Pilulæ Podophyllini et Quininae, B.P.C.—(Pil. Podoph. et Quinin.)—Podophyllin and Quinine Pills. *Syn.*—Poore's Pills. Each pill contains $\frac{1}{2}$ grain of resin of podophyllum, 1 grain of quinine sulphate, $\frac{1}{2}$ grain of dry extract of belladonna and 1 grain of aloes. Dose.—1 pill.

Tinctura Podophylli, B.P.C.—(Tinct. Podoph.)—Tincture of Podophyllum, Resin of podophyllum, about 1 in 30. Dose.—0·3 to 1 millilitre (5 to 15 minims). *This tincture was included in the British Pharmacopæia, 1914.*

Tinctura Podophylli Ammoniata, B.P.C.—(Tinct. Podoph. Ammon.)—Ammoniated Tincture of Podophyllum. Resin of podophyllum, 1 in 50, in aromatic spirit of ammonia. Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

PODOPHYLLUM

(Podoph.)

Podophyllum

Synonyms—Podophylli Rhizoma; Podophyllum Rhizome; May Apple Root; American Mandrake.

Podophyllum consists of the dried rhizome and roots of *Podophyllum peltatum* Linn. (Fam. Berberidaceæ), a small herb with a long perennial rhizome, common in the Eastern United States of America and in Canada. The rhizome is collected in the late summer, cut into pieces and dried.

The rhizome occurs in sub-cylindrical pieces, about 5 to 10 or more centimetres in length and about 5 millimetres thick; externally it is reddish-brown, and smooth or slightly wrinkled longitudinally. At intervals of about 5 to 10 centimetres, the rhizome is enlarged for about 1 to 2 centimetres to a thickness of about 1·5 centimetres. On the upper surface of the enlargement is the concave scar, surrounded by several circular leaf-scars, left by the fall of the flowering stem. On the under surface of the enlargement are up to about 12 roots or root-scars. The roots, when present, are cylindrical or flattened in shape, about

1.5 millimetres thick, brown and brittle. The rhizome breaks with a short fracture. The smoothed, transversely cut surface is white and starchy, unless the rhizome has been dried at a temperature sufficient to gelatinise the starch, in which case it is yellowish and horny; it shows a thin cork and a circle of about 20 to 30 small, oval, vascular bundles situated about half-way between the centre and circumference of the rhizome. Podophyllum may be identified and distinguished from Indian podophyllum by macerating the powdered drug in 20 parts of alcohol (90 per cent.) for ten minutes, and filtering; the filtrate gives a bright green colouration, but no brown precipitate, on the addition of a few drops of strong solution of copper acetate. The acid-insoluble ash is about 1 to 2.5 per cent., and the total ash about 4 to 7 per cent. It yields to alcohol (90 per cent.) from 11 to 16 per cent. of extractive. The drug has a slight, characteristic odour and a somewhat bitter and acrid taste.

The diagnostic **microscopical** characters are the epidermal cells, containing reddish-brown contents, those of the cylindrical portion being from four to eight times as long as they are wide, and sub-rectangular in shape, and those of the enlarged regions being more nearly isodiametric; the cluster-crystals of calcium oxalate, often more than 60 microns in diameter; the usually cylindrical sclerenchymatous cells.

Podophyllum contains a neutral, crystalline substance named podophyllotoxin (0.2 to 1 per cent.) and an amorphous resin, podophylloresin, both of which are purgative. The drug also contains quercetin and starch. Alkalis convert podophyllotoxin into the salt of an unstable, gelatinous acid, podophyllic acid, which readily loses water and furnishes crystalline picropodophyllin, which is isomeric with podophyllotoxin and is the lactone of podophyllic acid. The drug yields from 2 to 8 per cent. or more of resin of podophyllum.

Standard, B.P.—Podophyllum contains not more than 2 per cent. of other organic matter.

Podophyllum, in powder (Pulvis Podophylli : Pulv. Podoph.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Podophyllum is used almost entirely in the form of its resin.

Dose.—0.12 to 0.6 gramme (2 to 10 grains).

PODOPHYLLUM INDICUM

(Podoph. Ind.)

Indian Podophyllum

Synonyms—Podophylli Indici Rhizoma; Indian Podophyllum Rhizome.

Indian podophyllum consists of the dried rhizome and roots of *Podophyllum emodi* Wall. (Fam. Berberidaceæ), a plant growing in

the temperate forests on the lower slopes of the Himalayas. The roots are mainly detached, and form a large proportion of the drug.

The rhizome occurs in irregularly cylindrical or dorsiventrally flattened, contorted, knotty pieces, yellowish-brown to earthy-brown in colour. The pieces are about 2 to 4 centimetres long and 1 to 2 centimetres thick. On the upper surface are about 3 to 4 cup-shaped scars of aerial stems; on the under surface are numerous stout roots or circular root-scars. The rhizome breaks with a short fracture. The smoothed, transversely cut surface is pale brown and starchy, unless the temperature at which the rhizome has been dried has been sufficient to gelatinise the starch, in which case it is horny. It shows a large central pith, and a circle of about 20 radially elongated vascular bundles. Indian podophyllum may be identified and distinguished from podophyllum by macerating the powdered drug in 20 parts of alcohol (90 per cent.), and filtering; the filtrate gives a brown precipitate, but no green colouration, on the addition of a few drops of strong solution of copper acetate. The drug has a slight, characteristic odour and a somewhat bitter and acrid taste.

The diagnostic **microscopical** characters are the thin-walled, isodiametric cork cells; the occasional cluster-crystals of calcium oxalate, rarely exceeding 60 microns in diameter; the numerous, short, contorted sclerenchymatous cells; the absence of epidermal cells.

Indian podophyllum **contains** podophyllotoxin (1 to 4 per cent.) and podophylloresin. The drug yields from 6 to 12 per cent. of resin of podophyllum, which is not identical with that from podophyllum.

Standard, B.P.—Indian podophyllum contains not more than 2 per cent. of foreign organic matter.

Indian Podophyllum, in powder (*Pulvis Podophylli Indici* : *Pulv. Podoph. Ind.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Indian podophyllum is used as a source of podophyllum resin. *Tinctura Podophylli Indici*, prepared with 3.65 per cent. w/v of the resin of Indian podophyllum and alcohol (90 per cent.), has been administered in doses of 0.3 to 1 millilitre (5 to 15 minims).

Dose.—0.12 to 0.6 gramme (2 to 10 grains).

POTASSA 'SULPHURATA

(*Potass. Sulphur.*)

Sulphurated Potash

Synonym—Liver of Sulphur.

Sulphurated potash is a mixture of potassium polysulphides and other potassium compounds, including sulphite and thiosulphate, prepared by fusing 2 parts of potassium carbonate with 1 part of

sublimed sulphur. It occurs in the form of hard, solid fragments, greenish-yellow externally, pale liver-brown internally, the fractured surface rapidly changing to greenish-yellow on exposure to air. It has an odour of hydrogen sulphide and an acrid, alkaline taste. It readily absorbs moisture and carbon dioxide from the air, and undergoes oxidation. The aqueous solution is yellow and opalescent, and deposits, on standing, only a trace of insoluble matter; it is readily decomposed by acids with evolution of hydrogen sulphide and deposition of sulphur; when the solution is boiled with excess of hydrochloric acid and filtered, the filtrate responds to the tests for potassium. Sulphurated potash should be **stored** in well-closed containers.

Soluble in water (1 in 2).

Standard, B.P.—Sulphurated potash contains not less than 42 per cent. and not more than 45 per cent. of total sulphur.

Action and Uses.—Sulphurated potash is employed as a parasiticide, for “sulphur baths,” in rheumatism, and as a stimulant to the skin in chronic cutaneous diseases. When applied to the skin, it dissolves the epidermis and hair. After absorption it may lead to the formation of sulph-hæmoglobin. Sulphides are mainly excreted as sulphate. Lotions of sulphurated potash are used in acne, eczema, etc., and sulphurated potash is also prescribed with zinc sulphate as a lotion for skin diseases. Unguentum Potassii Polysulphidi is used in the treatment of scabies, two applications generally being sufficient. Sulphur baths are used for the same purpose. For veterinary purposes, baths containing 2 ounces in 1 pint of water are used in the treatment of mange in dogs. Sulphurated potash is **incompatible** with acids.

Preparations

Lotio Potassæ Sulphuratæ, B.P.C.—(Lot. Potass. Sulphurat.)—Lotion of Sulphurated Potash. *Syn.*—Lotio Zinci Sulphidi. Each fluid ounce contains zinc sulphide, prepared from 10 grains of sulphurated potash and 10 grains of zinc sulphate, in rose water.

Sal Aperiens Sulphuratum, B.P.C.—(Sal. Aper. Sulphurat.)—Sulphurated Aperient Salt. *Syn.*—Harrogate Salts. Sulphurated potash, 3 per cent., and potassium acid tartrate, 15 per cent., with exsiccated magnesium sulphate. Dose.—4 to 8 grammes (1 to 2 drachms).

Unguentum Potassii Polysulphidi, B.P.C.—(Ung. Potass. Polysulph.)—Potassium Polysulphide Ointment. *Syn.*—Marcussen's Ointment; Danish Ointment. It contains polysulphides of potassium equivalent to 12.5 per cent. of sublimed sulphur, with zinc hydroxide and benzaldehyde, in wool fat, yellow soft paraffin and liquid paraffin.

POTASSII ACETAS

(Pot. Acet.)

Potassium Acetate

Potassium acetate, $\text{CH}_3\cdot\text{COOK}$, may be obtained by the interaction of acetic acid and potassium carbonate, the product being fused to

remove moisture. It occurs as a white powder, or in granules, or in white, foliaceous, crystalline masses, having a satin-like lustre. The salt is odourless or has a faint, acetous odour, and a sharp, saline taste. It is very deliquescent, and the aqueous solution has an alkaline reaction to litmus. When heated to about 292° it fuses, and at a higher temperature it chars and decomposes with evolution of vapours having an empyreumatic odour. On ignition, it leaves a residue of potassium carbonate. It should be **stored** in well-closed, glass-stoppered containers.

Soluble in water (2 in 1) and alcohol (90 per cent.) (1 in 2).

Standard, B.P.—Potassium acetate contains not less than 99 per cent. of $C_2H_3O_2K$, calculated on the substance dried at 100° . Loss on drying at 100° , not more than 5 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for alkalinity, aluminium and calcium, chloride and sulphate.

Action and Uses.—Potassium acetate is rapidly absorbed and excreted, and is employed as a diuretic in dropsical conditions, especially of renal origin, and in febrile diseases. It decreases the acidity of the urine, being excreted as carbonate. It is best **administered** in dilute aqueous solution, its saline taste being disguised with syrup of orange. It is often given with infusion of buchu or scoparium, or as *Mistura Potassii Acetatis Composita*. Potassium acetate is added to solutions for hardening and preserving tissues in order to preserve their natural colour. Kaiserling's solutions contain:—(No. 1) Potassium nitrate, 10; potassium acetate, 30; solution of formaldehyde, 750; water, 1000. (No. 2) Potassium acetate, 50; glycerin, 100; water, 500. The material is steeped in No. 1 solution for four or five weeks, placed in alcohol for an hour or so until the original colour returns, and then kept in solution No. 2.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparation

Mistura Potassii Acetatis Composita, B.P.C.—(Mist. Pot. Acet. Co.)—Compound Potassium Acetate Mixture. *Syn.*—*Mistura Diuretica*. Each fluid ounce contains 20 grains of potassium acetate, 30 minims of spirit of nitrous ether, 20 minims of tincture of hyoscyamus and 60 minims of juice of scoparium, with infusion of buchu. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

POTASSII. BICARBONAS

(Pot. Bicarb.)

Potassium Bicarbonate

Potassium bicarbonate, or potassium hydrogen carbonate, may be prepared by saturating a strong aqueous solution of potassium carbonate with carbon dioxide. It occurs as colourless, odourless, monoclinic

prisms, or as a white, granular powder, with a saline, feebly alkaline taste. The aqueous solution rapidly loses carbon dioxide when heated, but the salt is not easily converted completely into carbonate. Potassium bicarbonate is completely converted into the carbonate when exposed for a short time to a low red heat.

Soluble in water (1 in 4); almost insoluble in alcohol (90 per cent.)

Standard, B.P.—Potassium bicarbonate contains not less than 99 per cent. and not more than the equivalent of 100.5 per cent. of KHCO_3 . Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for aluminium, calcium and insoluble matter, carbonate, chloride, sulphate and iron.

Action and Uses.—Potassium salts taken by the mouth have very little action attributable to the K ion, since the latter is rapidly excreted. They are usually more irritant to the stomach than sodium salts, and exert a more marked diuretic action. Injected subcutaneously or intravenously, potassium salts act as a powerful poison to the heart and nervous system. Potassium bicarbonate neutralises gastric hyperacidity; for this purpose it is taken twenty to thirty minutes after a meal. For its action after absorption, potassium bicarbonate is used to reduce the acidity of the urine, to maintain the alkali reserve of the blood and to prevent acidosis. It is used with expectorants, in the treatment of bronchial catarrh and bronchitis, to render the mucous secretion more fluid and more easily removable. It is valuable in acute catarrhal conditions of the bladder and urethra, and in the acute stage of gonorrhœa. Potassium bicarbonate is **administered** in aqueous solution. For neutralisation, 20 parts of potassium bicarbonate require about 14 parts of citric acid, or 15 parts of tartaric acid.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

POTASSII BROMIDUM

(Pot. Brom.)

Potassium Bromide

$\text{KBr} = 119.0$

Potassium bromide may be prepared by the interaction of potassium carbonate and iron bromide obtained by the direct combination of iron and bromine in the presence of water. It is also obtained by adding a slight excess of bromine to a hot, strong solution of potassium hydroxide, evaporating the solution of potassium bromide and bromate to dryness, and decomposing the bromate by heating with charcoal, the bromide being purified by crystallisation. It occurs in colourless or white, odourless, cubical crystals, or as a white, granular powder, with a strongly saline taste.

Soluble in water (1 in 2), boiling water (1 in 1), alcohol (90 per cent.) (1 in 200), boiling alcohol (90 per cent.) (1 in 17) and glycerin.

Standard, B.P.—Potassium bromide contains not less than 99 per cent. of KBr, calculated on the substance dried at 110°. Loss on drying at 110°, not more than 1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for free alkali, bromate, barium, chloride, sulphate and iron.

Action and Uses.—Potassium bromide is used for its action on the central nervous system. It depresses the psychical functions, the motor area, the medulla and cord. This effect is produced by a direct action of the drug on the nerve cells. By lowering the activity of both motor and sensory cells, the bromides are of great service in controlling epilepsy, and in the treatment of cerebral excitement. Through their influence on the medulla and cord they produce a general diminution of all the reflexes, and promote sleep by rendering the brain less sensitive to disturbing influences. From their effect on the pelvic centres of the cord, the bromides are powerful sexual sedatives and anaphrodisiacs. From the continued use of large doses, symptoms of bromism may arise; these consist of nausea and vomiting, mental dullness and lapse of memory, general muscular weakness and reduction of sensibility throughout the body. Various forms of skin eruption may follow the use of the bromides; acne of the head and shoulders is the commonest form, but abscesses and erythematous rashes are sometimes seen. Small doses of arsenic are said to prevent these symptoms. Bromides are also employed in other affections of the central nervous system, as in chorea, dysmenorrhœa and some forms of hysteria. Potassium bromide is employed to induce sleep when sleeplessness is caused by anxiety or overwork; it is useless in sleeplessness from pain. It is used with success in sea-sickness, often in combination with chloral formamide, and also in the sickness of pregnancy. It is a useful sedative in alcoholism, whooping cough, spasmodic asthma and nervous headache. Potassium bromide is **administered** in solution, sometimes with chloral hydrate and soluble phenobarbitone. Tablets should be dissolved in water since, if swallowed whole, they frequently cause pain in the stomach during solution. It is **incompatible** with salts of mercury and silver, oxidising substances, and with Spiritus Ætheris Nitrosi.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparations

Elixir Valerianæ Compositum, B.P.C.—(Elix. Valerian. Co.)—Compound Elixir of Valerian. *Syn.*—Elixir Bromidi et Valerianæ Compositum; Compound Elixir of Bromide and Valerian. Each fluid ounce contains 7½ grains each of potassium bromide and chloral hydrate, and 15 minims of liquid extract of valerian, with oils of orange, lemon, coriander and anise, alcohol (90 per cent.), syrup and distilled water. Dose—15 to 30 millilitres (½ to 1 fluid ounce).

Liquor Bromidi Compositus, B.P.C.—(Liq. Brom. Co.)—Compound Bromide Solution. *Syn.*—Liquor Bromochloral Compositus. Each fluid drachm contains 15 grains of chloral hydrate and 15 grains of potassium bromide, with extract of cannabis, liquid extract of hyoscyamus, tincture of orange, glycerin and distilled water. Dose.—2 to 8 millilitres (½ to 2 fluid drachms).

Liquor Potassii Arsenatis et Bromidi, B.P.C.—(Liq. Pot. Arsen. et Brom.)—Solution of Potassium Arsenate and Bromide. *Syn.*—Liquor Arsenii Bromidi; Clemens' Solution. A solution containing potassium arsenate and potassium bromide, prepared from arsenic trioxide, 1 per cent. w/v, with potassium bicarbonate, bromine and distilled water. Dose.—0.12 to 0.5 millilitre (2 to 8 minims).

Mistura Bromidi Composita, B.P.C.—(Mist. Brom. Co.)—Compound Mixture of Bromides. Each fluid ounce contains 10 grains each of the bromides of ammonium, potassium and sodium, with tincture of nux vomica and solution of carmine, glycerin and chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Syrupus Potassii Bromidi et Pilocarpinæ, B.P.C.—(Syr. Pot. Brom. et Pilocarp.)—Syrup of Potassium Bromide and Pilocarpine. Potassium bromide, 10 per cent. w/v, and pilocarpine hydrobromide, 0.005 per cent. w/v, with glycerin and syrup of orange; each fluid drachm contains about $5\frac{1}{2}$ grains of potassium bromide and $\frac{1}{16}$ grain of pilocarpine hydrobromide. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

POTASSII CARBONAS

(Pot. Carb.)

Potassium Carbonate

Synonym—Salt of Tartar.

Potassium carbonate was formerly obtained from wood ashes in countries where wood was plentiful. It is now largely obtained from potassium chloride, occurring in natural deposits in Europe and America, by passing carbon dioxide into a solution of the chloride in the presence of hydrated magnesium carbonate. A sparingly soluble double salt of magnesium carbonate and potassium bicarbonate is precipitated and, after separation, is decomposed by treatment with magnesium oxide, when a solution of potassium carbonate is obtained. Potassium carbonate is also obtained by heating the bicarbonate obtained by passing carbon dioxide into a solution of potassium hydroxide prepared by the electrolysis of potassium chloride solution. The salt approximates to the formula, $K_2CO_3 \cdot H_2O$, and occurs as an odourless, very deliquescent, white, crystalline powder, with a strongly alkaline taste. When heated between 200° and 300° it becomes anhydrous; at a bright red heat it fuses and at a white heat it volatilises. It should be **stored** in well-closed containers. "Pearl-ash" and "American potash" are forms of crude potassium carbonate.

Soluble in water (1 in 1); insoluble in alcohol.

Standard, B.P.—Potassium carbonate contains not less than 99 per cent. of K_2CO_3 , calculated on the substance dried between 200° and 300° . Loss on drying between 200° and 300° , not less than 14 per cent. and not more than 18 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for aluminium, calcium, insoluble matter, chloride, sulphate and iron.

Action and Uses.—The properties of potassium carbonate resemble those of potassium bicarbonate, but it is more caustic and irritating, and is rarely given internally. It is sometimes applied externally as a lotion in eczema and urticaria (30 grains to 1 pint).

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

POTASSII CHLORAS

(Pot. Chloras)

Potassium Chlorate

Potassium chlorate is usually obtained by the electrolysis of a hot aqueous solution of potassium chloride, when the chloride is oxidised at the anode to the chlorate. It occurs in colourless crystals or as a white powder, having a cool, saline taste. When heated to about 370° , it melts and evolves oxygen, leaving a residue of potassium chloride and potassium perchlorate. When treated with hydrochloric acid, the liquid becomes yellow and a mixture of chlorine and chlorine peroxide is evolved. Potassium chlorate is permanent in air, but is liable to explode in contact with readily oxidisable substances such as phosphorus, sulphur, or organic compounds, especially if triturated or subjected to percussion.

Soluble in water (about 1 in 16), boiling water (about 1 in 2), alcohol (60 per cent.) (about 1 in 152) and glycerin (about 1 in 30); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Potassium chlorate contains not less than 99 per cent. of KClO_3 . Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for chloride and sulphate.

Action and Uses.—Potassium chlorate is rapidly absorbed, and is continuously eliminated by the salivary glands, mucous membranes, and kidneys. It is employed in foul conditions of the mouth and pharynx in the belief that putrefying organic matter is oxidised under such conditions. Large doses are actively poisonous; methæmoglobin is set free in the blood serum, the red corpuscles are disintegrated, and cyanosis results from deficient oxygenation of the blood, death occurring from respiratory failure; there may, however, be complete recovery from the acute symptoms, death occurring five or six weeks later from nephritis caused by blocking of the fine renal tubules with the disintegrated blood debris. The salt is used **internally**, but should be given only with care to young children, and never when there is renal disease. Potassium chlorate is used as a mouth-wash (1 in 40) when the gums are inflamed or spongy, for aphthous conditions, in tonsillitis, and in the stomatitis following the prolonged use of mercury. It is

administered in mixtures with dilute hydrochloric acid, or in alkaline mixtures with sodium salicylate. Lozenges, pastilles and tablets, with or without borax, are prepared. It is also used in gargles with borax, phenol, glycerin, or ferric chloride. Potassium chlorate is employed in the preparation of Gargarisma Chlorig, which is used as a deodorant and for the treatment of septic throat. It is **incompatible** with sulphur, charcoal and other readily oxidisable substances, and, in mixing it with any dry substance, friction and percussion should be avoided. Tablets of potassium chlorate should not be allowed to come in contact with matches or surfaces containing phosphorus compounds. In cases of **poisoning** by potassium chlorate, the stomach should be evacuated and alkali bicarbonates administered.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

Preparations

Gargarisma Chlorig, B.P.C.—(Garg. Chlor.)—Chlorine Gargle. A chlorinated solution prepared by dissolving in water the products of the interaction of potassium chlorate and hydrochloric acid. It should be diluted before use with one or more parts of water.

Gargarisma Potassii Chloratis, B.P.C.—(Garg. Pot. Chlorat.)—Potassium Chlorate Gargle. Potassium chlorate, about 1 in 40, in distilled water acidified with dilute hydrochloric acid.

Tabellæ Potassii Chloratis et Boracis, B.P.C.—(Tab. Pot. Chlorat. et Borac.)—Tablets of Potassium Chlorate and Borax. Each tablet contains 3 grains of potassium chlorate and 2 grains of borax. **Dose.**—1 or 2 tablets.

Trochisci Potassii Chloratis, B.P.C.—(Troch. Pot. Chlorat.)—Potassium Chlorate Lozenges. Each lozenge contains 3 grains of potassium chlorate.

This lozenge, containing 0.2 gramme of potassium chlorate, was included in the British Pharmacopœia, 1914.

POTASSII CHLORIDUM

(Pot. Chlorid.)

Potassium Chloride

KCl = 74.55

Potassium chloride is obtained from natural deposits, chiefly from carnallite, a double chloride of potassium and magnesium. It may also be prepared by treating a solution of potassium carbonate with hydrochloric acid until only faintly acid, filtering, evaporating, and drying the salt at 105°. Potassium chloride occurs as colourless, odourless, cubical crystals or quadrangular prisms, or as a crystalline powder, having a saline and slightly bitter taste resembling that of table salt; it is anhydrous, and permanent in the air. It decrepitates when heated. In contact with a non-luminous flame it produces a violet-coloured flame without any tinge of yellow.

Soluble in water (1 in 3); insoluble in dehydrated alcohol and ether.

Standard.—Potassium chloride, determined by the method of the British Pharmacopœia for Sodii Chloridum, contains not less than 99·5 per cent. of KCl, calculated on the substance dried at 130°; each millilitre of N/10 silver nitrate is equivalent to 0·007455 gramme of KCl. Loss on drying at 130°, not more than 1·0 per cent. The aqueous solution (1 in 10) is neutral to litmus. Arsenic limit, 1 part per million. Lead limit, 5 parts per million. It complies with the limit tests for sulphates, iron, bromides and iodides, barium, and calcium and magnesium in Sodii Chloridum.

Action and Uses.—Potassium chloride does not exhibit the depressant action of the K ion on the tissues, because it is excreted with such extreme rapidity that the blood never contains it in sufficient concentration to produce the specific effect. It has been recommended for use as a table salt in place of sodium chloride for gouty and rheumatic patients, as a means of retarding the formation of biurates in the tissues. A mixture composed of potassium chloride, 16 parts, sodium chloride, 8 parts, and lithium benzoate, 1 part, has also been recommended for the same purpose.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

POTASSII CITRAS

(Pot. Cit.)

Potassium Citrate

Potassium citrate, $\text{COOK}\cdot\text{C}(\text{OH})(\text{CH}_2\cdot\text{COOK})_2\cdot\text{H}_2\text{O}$, may be prepared by neutralising citric acid with potassium carbonate. It occurs as an odourless, white, granular or crystalline powder, with a cooling, saline taste. The aqueous solution is alkaline to litmus but not to phenolphthalein. Potassium citrate is slightly deliquescent in moist air. It should be **stored** in well-closed containers.

Soluble in water (1 in 1), glycerin (1 in 2) and alcohol (60 per cent.) (1 in 9); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Potassium citrate contains not less than 99 per cent. of $\text{C}_6\text{H}_5\text{O}_7\text{K}_3\cdot\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for alkalinity or acidity, tartrate, oxalate, chloride and sulphate.

Action and Uses.—Potassium citrate, when taken internally, is partly absorbed and oxidised in the tissues to alkali carbonate, in which form it is excreted. It therefore renders the blood and urine more alkaline, having the remote effect of the bicarbonates without their neutralising action upon gastric secretion. As the alkali citrates are absorbed more readily than the tartrates, their laxative action is

less marked. Potassium citrate is employed principally to increase the quantity of urine and render it alkaline in gout and rheumatism, in catarrhal conditions of the bladder and urethra, and as a mild diaphoretic and febrifuge in feverish conditions. It is employed as a prophylactic against post-scarlatinal nephritis and in the treatment of acute nephritis, and in large doses in the acid intoxication of diabetes; it is a useful expectorant in the early stages of bronchitis. It is **administered** in mixtures, and Potassii Citras Effervescens is a convenient antacid for daily use by gouty and rheumatic subjects.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Mistura Ammonii Acetatis Composita, B.P.C.—(Mist. Ammon. Acet. Co.)—Compound Ammonium Acetate Mixture. *Syn.*—Mistura Diaphoretica. Each fluid ounce contains 20 grains of potassium citrate and 20 minims each of strong solution of ammonium acetate, spirit of nitrous ether and spirit of chloroform, in camphor water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Potassii Citras Effervescens, B.P.C.—(Pot. Cit. Efferv.)—Effervescent Potassium Citrate. About 1 in 6. Dose.—4 to 8 grammes (1 to 2 drachms).

POTASSII CYANIDUM

(Pot. Cyanid.)

Potassium Cyanide

KCN = 65.10

Potassium cyanide may be prepared by heating potassium ferrocyanide to bright redness, when the products are potassium cyanide, iron, carbon and nitrogen, or with potassium carbonate, when potassium cyanide, potassium cyanate, carbon dioxide and iron are formed. The so-called "double salt" may be obtained by fusing the ferrocyanide with metallic sodium, when a mixture of potassium cyanide and sodium cyanide in the proportion of 2 to 1 is obtained. Pure potassium cyanide may be obtained by Beilby's process, in which a mixture of fused potassium carbonate and carbon is treated with ammonia gas, the only by-product being water. The alkali cyanides are now manufactured synthetically, principally from sodamide or from calcium cyanamide.

Potassium cyanide occurs in the form of white, cubical crystals, or in white, opaque, fused masses, and it is sometimes fused into sticks. It is deliquescent, and has the odour of hydrocyanic acid. The aqueous solution is strongly alkaline to litmus, and dissolves iron, zinc, copper and nickel with evolution of hydrogen; in the presence of oxygen it dissolves silver and gold, but for the extraction of gold, sodium cyanide is exclusively used. The aqueous solution is decomposed on exposure to air, absorbing carbon dioxide; on boiling, it is partly decomposed, yielding

ammonia and potassium formate. Potassium cyanide fuses at a dull red heat, and, in the absence of moisture, volatilises unchanged at a full red heat. When heated with a metallic oxide, it gives potassium cyanate and the metal, thus acting as an energetic reducing agent. When fused with sulphur, it yields potassium thiocyanate, and when heated with potassium chlorate or nitrate, it explodes violently.

Commercial fused potassium cyanide occurs in various strengths (equivalent to 30, 40, and 90 to 95 per cent. of KCN), but it is easily obtained of 96 per cent. strength. The so-called "double salt," containing sodium and potassium cyanides equivalent to 98 to 100 per cent. of KCN, is the cheapest product, and serves most of the purposes for which potassium cyanide is required. Sodium cyanide which contains cyanogen equivalent to about 130 per cent. of KCN is also obtainable. Potassium cyanide should be **stored** in well-closed containers. It is intensely poisonous, and great caution should be observed in handling it.

Soluble in water (1 in 2.5), alcohol (almost entirely, 1 in 100), boiling alcohol (1 in 80) and in weaker alcohol, in larger proportion.

Uses.—Potassium cyanide is very rarely **administered** internally. It is employed by entomologists for killing insects without injury. For this purpose the salt is usually broken into small pieces, and a layer, three-quarters to one inch deep, is placed at the bottom of a wide-mouthed bottle provided with a well-fitting cork; plaster of Paris cream is poured over the cyanide to form a level floor, and allowed to set; the bottle is constantly filled with a poisonous vapour. Potassium cyanide removes the stain of silver nitrate from the skin. In cases of **poisoning** by potassium cyanide, large draughts of ferrous sulphate and water should be given at once, followed immediately by solution of sodium carbonate or magnesia, and by an emetic or the use of the stomach pump. Stimulants and artificial respiration should be used.

POTASSII FERRICYANIDUM.—Potassium ferricyanide, $K_3Fe(CN)_6$, occurs as red crystals. It is used largely in photography and as a reagent.

POTASSII FERROCYANIDUM.—Potassium ferrocyanide, $K_4Fe(CN)_6 \cdot 3H_2O$, occurs as odourless, translucent, soft, lemon-yellow tablets or prisms. It is used as a reagent.

SODII NITROPRUSSIDUM.—Sodium nitroprusside, $Na_2Fe(CN)_5NO \cdot 2H_2O$, occurs as large, ruby-red, non-deliquescent crystals, which are not dehydrated at 100° . The aqueous solution decomposes rapidly in sunlight or on heating, with precipitation of prussian blue. It is used largely as a reagent for acetone in urine. A few drops of saturated solution are added to a small quantity of the urine and solution of ammonia is floated on the mixture; a magenta-coloured ring is produced. It is also used to detect soluble sulphides with which it gives a deep purple colour.

SODII THIOCYANAS—Sodium thiocyanate, sulphocyanide, or rhodanide, occurs as colourless crystals, readily soluble in water. It has been administered in the form of a solution in doses of 0.12 gramme (2 grains), thrice daily, for reducing arterial hypertension. The dose may be increased gradually up to 1 gramme (15 grains) a day.

POTASSII DICHROMAS

(Pot. Dichrom.)

Potassium Dichromate*Synonym*—Potassium Bichromate.

Potassium dichromate may be obtained by roasting chrome iron-stone with lime in the presence of air, treating the resulting chromate with a potassium salt and, subsequently, with an acid. It occurs in large, orange-red, transparent, triclinic, odourless prisms, having an acid, metallic taste. The aqueous solution is acid to litmus. The salt melts unchanged below a dull red heat, but at higher temperatures it is decomposed, yielding chromium oxide, potassium chromate and oxygen. 1 gramme dissolved in 20 millilitres of water and 5 millilitres of hydrochloric acid forms, on the gradual addition of 1 millilitre of alcohol, a green solution.

Soluble in water (1 in 10), boiling water (1 in 1.2); insoluble in alcohol.

Standard.—Potassium dichromate contains not less than 99 per cent. of $\text{K}_2\text{Cr}_2\text{O}_7$. 2 grammes complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 2 grammes dissolved in 20 millilitres of water shows no turbidity on making distinctly alkaline with solution of ammonia and adding ammonium oxalate solution (limit of aluminium and calcium).

Assay.—Dissolve about 0.15 gramme, accurately weighed, in 25 millilitres of water in a glass-stoppered flask; add 2 grammes of potassium iodide, dilute to about 250 millilitres, add 5 millilitres of hydrochloric acid, and allow to stand for about 10 minutes; titrate the liberated iodine with N/10 sodium thiosulphate, using starch mucilage as indicator; each millilitre of N/10 sodium thiosulphate is equivalent to 0.004904 gramme of $\text{K}_2\text{Cr}_2\text{O}_7$.

Action and Uses.—Potassium dichromate has been used in the form of pills, prepared by triturating the salt with kaolin and massing with kaolin ointment or wool fat, in the treatment of gastric ulcer. It is **incompatible** with alcohol and all reducing agents. In cases of poisoning by potassium dichromate, the stomach pump or an emetic of zinc sulphate or mustard should be used, followed by chalk or white of egg in milk, and barley water. A solution of potassium dichromate, 2.5 parts, and sodium sulphate, 1 part, in water, 100 parts, is known as Müller's fluid, and is used for hardening tissues, post mortem, prior to histological examination.

Dose.—0.006 to 0.012 gramme ($\frac{1}{10}$ to $\frac{1}{8}$ grain).

POTASSII CHROMAS.—Potassium chromate, K_2CrO_4 , may be prepared by the interaction of aqueous solutions of potassium dichromate and potassium hydroxide and occurs in lemon-yellow crystals. It is soluble in water, but insoluble in alcohol.

POTASSII FORMAS

(Pot. Form.)

Potassium Formate

Potassium formate, $\text{H}\cdot\text{COOK}$, may be prepared by saturating an aqueous solution of formic acid with potassium carbonate or hydroxide, and evaporating. The solution crystallises with difficulty. Potassium formate occurs in the form of anhydrous, deliquescent, transparent, cubical crystals, or as a crystalline powder, having a bitter, saline taste.

Very **soluble** in water (3 in 1); less soluble in alcohol; insoluble in ether.

Standard.—Potassium formate, determined by the method for *Calcii Formas*, contains not less than 95 per cent. of CHO_2K ; each millilitre of $\text{N}/10$ potassium permanganate is equivalent to 0.004205 gramme of CHO_2K . Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Action and Uses.—Potassium formate resembles, in its action, the formates of sodium and calcium. It is **administered** in solution in mixture form; *Elixir Formatum Compositum* is a palatable preparation of the formates.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

Preparation

Elixir Formatum Compositum, B.P.C.—(*Elix. Form. Co.*)—Compound Elixir of Formates. *Syn.*—Elixir Formatum cum Strychnina; Elixir of Formates with Strychnine. Each fluid drachm contains about 3 grains each of sodium formate and potassium formate, and $1\frac{1}{4}$ minims of solution of strychnine hydrochloride, with simple elixir. *Dose.*—4 to 8 millilitres (1 to 2 fluid drachms).

POTASSII GLYCEROPHOSPHAS LIQUIDUS

(Pot. Glycerophosph. Liq.)

Solution of Potassium Glycerophosphate

Solution of potassium glycerophosphate is an aqueous solution containing about 50 per cent. of the neutral potassium salts of α - and β -glycerophosphoric acids, and may be prepared by the interaction of potassium carbonate and glycerophosphoric acid. It occurs as a colourless or not more than faintly yellow, syrupy liquid. A solution containing 75 per cent. is also found in commerce; it occurs as a thick, syrupy liquid, often partly crystallised.

Miscible in all proportions with water.

Standard.—Solution of potassium glycerophosphate, determined by the method for *Sodii Glycerophosphas Liquidus*, contains not less than 48 and not more than 52 per cent. by weight of $\text{C}_3\text{H}_7\text{O}_6\text{PK}_2, 3\text{H}_2\text{O}$;

each millilitre of N/1 hydrochloric acid is equivalent to 0.3023 gramme of $C_3H_7O_6PK_2 \cdot 3H_2O$. Specific gravity, 1.38 to 1.42. Arsenic limit, 2.5 parts per million. Lead limit, 10 parts per million. Mix 5 grammes in a stoppered cylinder with 20 millilitres of dehydrated alcohol, add 5 grammes of recently ignited calcium sulphate, shake until the supernatant liquid is practically clear, filter into a 100 millilitre beaker, wash the residue in a cylinder with a few millilitres of dehydrated alcohol, evaporate the filtrate and washings, dry the residue at 70° for one hour, and weigh; the residue weighs not more than 0.10 gramme (limit of free glycerin). Limit of free alkali (calculated as K_2CO_3), 0.5 per cent. Limit of free phosphate (calculated as P_2O_5), 0.5 per cent.

Action and Uses.—Potassium glycerophosphate resembles, in its action, sodium and calcium glycerophosphates (see Acidum Glycerophosphoricum). It is given with other glycerophosphates in the form of Glycerinum Glycerophosphatum Compositum, Syrupus Glycerophosphatum Compositus, or other compound syrups.

Dose.—0.6 to 2 grammes (10 to 30 grains).

POTASSII GUAIACOLSULPHONAS

(Pot. Guaiacolsulph.)

Potassium Guaiacolsulphonate

Potassium guaiacolsulphonate, $C_6H_3(OCH_3)(OH)SO_3K$ (1 : 2 : 3), is the potassium salt of guaiacolsulphonic acid, obtained by the action of sulphuric acid on guaiacol at 70° to 80° , converting the guaiacolsulphonic acid produced into the barium salt, which is then decomposed by potassium sulphate to form potassium guaiacolsulphonate. It occurs as a white, odourless powder, having a taste at first bitter and afterwards sweet. The aqueous solution is slightly alkaline to litmus, and is not precipitated by barium chloride solution; with ferric chloride solution an intense violet-blue colour is produced, which disappears on the addition of ammonia or strong solutions of alkali sulphates or chlorides. On the addition of sulphuric acid and a trace of formaldehyde, a reddish-violet colour is obtained. On the addition of 1 millilitre of nitric acid to 10 millilitres of a warm 10 per cent. aqueous solution, the solution becomes deep red, and deposits yellow crystals on cooling; the filtrate remains red, and yields a white precipitate on the addition of barium nitrate solution.

Readily **soluble** in water; almost insoluble in alcohol; insoluble in dehydrated alcohol, ether and oils.

Standard.—Potassium guaiacolsulphonate yields not less than 35.2 per cent. of sulphated ash, equivalent to not less than 98 per cent. of $C_7H_7O_5SK$. Lead limit, 20 parts per million. 1 gramme complies with the limit test for sulphates.

Action and Uses.—Potassium guaiacolsulphonate is used in the treatment of phthisis, bronchitis, pneumonia and intestinal catarrh. It may be **administered** in cachets or tablets, or in mixtures flavoured with syrup of orange.

Dose.—0·5 to 1 gramme (8 to 15 grains).

POTASSII HYDROXIDUM

(Pot. Hydrox.)

Potassium Hydroxide

KOH = 56·10

Synonyms—Potassa Caustica; Caustic Potash.

Potassium hydroxide is usually obtained by the electrolysis of an aqueous solution of potassium chloride. It occurs in white sticks, pellets, or fused masses, which are dry, hard and brittle, breaking with a crystalline fracture. It is powerfully alkaline and corrosive, and quickly destroys organic tissues. Exposed to the air, it rapidly absorbs moisture and carbon dioxide. The variety described as “purified by alcohol” was prepared by solution in alcohol, filtration to remove the less soluble carbonate and other salts, and evaporation to dryness. Potassium hydroxide should be **stored** in well-closed containers.

Soluble in water (1 in 0·95) and alcohol (90 per cent.) (1 in 3); very soluble in boiling dehydrated alcohol.

Standard, B.P.—Potassium hydroxide contains not less than 85 per cent. of total alkali, calculated as KOH. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for carbonate, aluminium, iron and matter insoluble in hydrochloric acid, chloride and sulphate.

Action and Uses.—Potassium hydroxide is a powerful caustic, and has been used externally to destroy nævi and warts. A solution is used as a cuticle solvent. Liquor Potassii Hydroxidi, in doses of 0·6 to 2 millilitres (10 to 30 minims), freely diluted, is antacid and diuretic, but for internal use the bicarbonates are almost always superior. Vienna paste (Pasta Potassæ et Calcis) is a mixture of potassium hydroxide and calcium hydroxide made into a paste with alcohol or glycerin. In cases of **poisoning** by potassium hydroxide, large draughts of water containing vinegar, acetic acid, citric acid, or lemon juice should be given, followed by demulcent drinks and olive oil.

Preparations

Liquor Potassii Hydroxidi, B.P.—(Liq. Pot. Hydrox.)—Solution of Potassium Hydroxide. *Syn.*—Liquor Potassæ; Solution of Potash. An aqueous solution containing 5 per cent. w/v of total alkali, calculated as KOH (limits, 4·75 to 5·25). It should be stored in well-closed bottles of green glass. It is administered in doses of 0·6 to 2 millilitres (10 to 30 minims), freely diluted.

POTASSII HYDROXYQUINOLINI SULPHAS

(Pot. Hydroxyquinolin. Sulph.)

Potassium Hydroxyquinoline Sulphate*Synonym*—Potassium Oxyquinoline Sulphate.

Potassium hydroxyquinoline sulphate approaches in composition to $C_9H_6(OH)N, HSO_4K$, and may be prepared by treating two molecular proportions of 8-hydroxyquinoline with one of potassium pyrosulphate in alcoholic solution. Some doubt exists concerning its constitution. It has been regarded also as a mixture of approximately equimolecular proportions of 8-hydroxyquinoline sulphate, $(C_9H_6(OH)N)_2, H_2SO_4$, and potassium sulphate, and as a mixture of 8-hydroxyquinoline and potassium acid sulphate. It occurs as a light yellow, microcrystalline powder. The aqueous solution is strongly acid in reaction (pH about 3.0). The aqueous solution, on the addition of ferric chloride solution, produces a bright green colouration; on the careful addition of alkali the base is precipitated, but redissolves in excess; on the addition of bromine a precipitate of a dibromohydroxyquinoline is obtained. The solution also yields precipitates with traces of salts of various heavy metals; one part of copper in a million is detectable. The reaction is due to the 8-hydroxyquinoline, which has been suggested also for use in the determination of magnesium and aluminium.

Soluble in water; sparingly soluble in alcohol; insoluble in ether.

Standard.—Potassium hydroxyquinoline sulphate partly liquefies between 172° and 178° (the melting-point of 8-hydroxyquinoline sulphate). Sulphated ash, not less than 30 and not more than 33 per cent.

Action and Uses.—Potassium hydroxyquinoline sulphate has antiseptic and deodorant properties. It is rarely employed internally. **Externally**, as a lotion or application to the skin in mycosis, eczema, etc., it is used in strengths of from 1 in 500 to 1 in 2000. A solution containing 15 grains to the pint is said to be equal in germicidal properties to a 1 in 40 solution of phenol. It has been used as a spermicide in the form of jelly, pessaries and tablets.

POTASSII HYPOPHOSPHIS

(Pot. Hypophosph.)

Potassium Hypophosphite $KPH_2O_2 = 104.1$

Potassium hypophosphite may be prepared by interaction between potassium carbonate and calcium hypophosphite in aqueous solution. It occurs in odourless, very deliquescent, white, opaque, hexagonal plates, or crystalline masses, or more usually as a granular powder, having a pungent, saline and bitterish taste. The aqueous solution is

neutral or slightly alkaline to litmus. When heated, spontaneously inflammable hydrogen phosphide is evolved. It reduces silver nitrate, copper sulphate and mercuric chloride solutions. When triturated with nitrates, chlorates and other oxidising agents, explosions are liable to occur. Boiled with potassium hydroxide solution, hydrogen is given off and potassium phosphate and phosphite are formed. It is oxidised rapidly on evaporation with nitric acid.

Soluble in water (1 in 0.6), boiling water (1 in 0.3), alcohol (90 per cent.) (1 in 7.5) and boiling alcohol (90 per cent.) (1 in 3.5); insoluble in ether.

Standard.—Potassium hypophosphite, determined by the method for Calcii Hypophosphis, contains not less than 98 per cent. of KPH_2O_2 , calculated on the substance dried over sulphuric acid; each millilitre of N/10 iodine is equivalent to 0.005207 gramme of KPH_2O_2 . Loss on drying over sulphuric acid, not more than 2 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies with the limit test for phosphate in Calcii Hypophosphis.

Action and Uses.—Potassium hypophosphite has the general properties of the hypophosphites (see Acidum Hypophosphorosum Dilutum). It is **administered** with other hypophosphites in the form of compound syrup of hypophosphites.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

POTASSII IODIDUM

(Pot. Iod.)

Potassium Iodide

KI = 166.0

Potassium iodide may be prepared by the action of potassium carbonate on a solution of iron iodide prepared by the direct combination of iron and iodine in the presence of water. It may also be obtained by the action of excess of iodine on a warm solution of potassium hydroxide, the resulting solution of potassium iodide and iodate being evaporated to dryness, and the residue heated with charcoal to reduce the iodate to iodide, which is extracted with water and purified by crystallisation. It occurs in colourless, odourless, translucent or opaque crystals, or as a granular powder, having a slightly bitter, saline taste. The salt decrepitates on heating, fuses at a low red heat, and at a higher temperature it volatilises without decomposition. The aqueous solution has a faintly alkaline reaction; it readily dissolves iodine, forming a dark brown solution containing potassium triiodide, KI_3 , which has been obtained in the form of black, acicular crystals; the aqueous solution also dissolves certain iodides insoluble in water, such as mercuric iodide, double iodides being formed.

Soluble in water (1 in 0.7), alcohol (90 per cent.) (1 in 12) and glycerin (1 in 2).

Standard, B.P.—Potassium iodide contains not less than 99 per cent. of KI, calculated on the substance dried at 110°. Loss on drying at 110°, not more than 1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for free alkali, iodate, barium, cyanide and sulphate.

Action and Uses.—Potassium iodide increases the flow of bronchial secretion, and for this reason is used, often with tincture of stramonium, in some forms of asthma and chronic bronchial catarrh; it is rapidly excreted. Potassium iodide has no specific spirochætidal action, but it aids the absorption of newly formed fibrous tissue, and to this property is attributed its value in the treatment of the later stages of syphilis—the resolution of the fibrous tissue allowing other remedies, which are usually administered with it, an opportunity to attack the spirochætes. For a similar reason it is employed in the treatment of actinomycosis. Potassium iodide is used in the treatment of aneurism and arteriosclerosis, and also in chronic rheumatism and allied fibrositic conditions. In cases of high arterial tension and angina pectoris it may help by relaxation of the arterioles. Potassium iodide is used in the treatment of goitre; it is used as a prophylactic in districts where the condition is endemic, but the administration is prolonged and overdosage must be avoided, since too great a quantity may result in a condition of hyperthyroidism. In the early treatment of exophthalmic goitre it may be useful, and may cause a sufficient remission of the symptoms to give operative treatment a better chance of success, but treatment beyond two or three weeks is not usually of any value, the symptoms tending to recur. Potassium iodide is given in cases of chronic lead and mercury poisoning. In the latter condition the doses should be small in order to avoid too rapid liberation of the metal from the tissues, with risk of acute symptoms. Intolerance to iodides sometimes occurs, the symptoms being nasal catarrh, lachrymation, skin rashes of a variable character, headache and depression. Some patients showing idiosyncrasy to small doses appear to tolerate larger doses. Potassium iodide should not be given in pulmonary tuberculosis.

It is best **administered** in solution freely diluted, since concentrated solutions have an irritant action on the gastric mucosa. When it is desired to give large doses of iodide, as in the treatment of actinomycosis, it is better to avoid the depressant action of the potassium ion by substituting the sodium salt. Potassium iodide has been employed as a test for renal function. 2 grammes of the salt is given, and the urinary elimination estimated; in twelve hours 60 to 80 per cent. is excreted by the normal kidneys. Externally, in the form of Linimentum Potassii Iodidi cum Sapone, it is used as a local application to enlarged glands. Potassium iodide is **incompatible** with spirit of nitrous ether, solutions of ferric salts, dilute nitro-hydrochloric acid, solution of strychnine hydrochloride, potassium chlorate and bismuth subnitrate.

Dose.—0.3 to 2 grammes (5 to 30 grains).

Preparations

Linimentum Potassii Iodidi, B.P.C.—(Lin. Pot. Iod.)—Liniment of Potassium Iodide. A liquid preparation containing potassium iodide, 1 in 10, with soft soap, glycerin, oil of lemon and alcohol (60 per cent.).

Linimentum Potassii Iodidi cum Sapone, B.P.C.—(Lin. Pot. Iod. c. Sap.)—Liniment of Potassium Iodide with Soap. A solid preparation containing potassium iodide, about 1 in 7, with curd soap, glycerin, oil of lemon and distilled water.

This liniment was included in the British Pharmacopœia, 1914.

Unguentum Potassii Iodidi, B.P.C.—(Ung. Pot. Iod.)—Potassium Iodide Ointment. Potassium iodide, 10 per cent., with potassium carbonate and distilled water in benzoinated lard.

This ointment was included in the British Pharmacopœia, 1914.

POTASSII NITRAS

(Pot. Nitræs)

Potassium Nitrate

Synonyms—Nitre; Saltpetre.

Potassium nitrate occurs naturally in various hot countries, where it is obtained by lixiviation from certain soils containing nitrogenous excrements. It is also obtained by the interaction of hot, saturated solutions of sodium nitrate and potassium chloride; sodium chloride is precipitated, and the clear liquid deposits potassium nitrate on cooling. Potassium nitrate occurs as a white, crystalline powder or as colourless crystals; it is odourless, and has a cooling, saline taste. The aqueous solution is neutral to litmus. When heated to about 353° , the salt melts and forms, on cooling, a solid mass known as "sal prunella," usually supplied in the form of small balls; at a higher temperature it is decomposed, giving off oxygen and then some of its nitrogen, and leaving a residue of potassium nitrate, nitrite and oxide. In contact with red hot carbon it deflagrates.

Soluble in water (1 in 4), boiling water (10 in 4); sparingly soluble in alcohol (90 per cent.).

Standard, B.P.—Potassium nitrate contains not less than 99 per cent. of KNO_3 . Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for ammonium compounds, copper, zinc, chloride and sulphate.

Action and Uses.—Potassium nitrate, given internally, has a marked salt action, causing an increased flow of urine and, in large doses, irritation of the kidneys and gastro-intestinal tract. It is employed as a diuretic, but is better avoided when there is inflammation of the stomach, kidneys or bladder. Potassium nitrate should be **administered** in dilute solution. It is occasionally used in gargles with potassium chlorate for inflamed throats, and nitre or saltpetre

balls (sal prunella) are sucked for a similar purpose. Blotting-paper saturated with a strong solution of potassium nitrate and dried is burned and the fumes inhaled for asthma. Asthma powders and papers are impregnated with potassium nitrate to assist combustion.

Dose.—0.3 to 1 gramme (5 to 15 grains).

AMMONII NITRAS.—Ammonium nitrate, NH_4NO_3 , occurs in colourless, odourless crystals. On heating, it melts at 165° and is decomposed at higher temperatures, chiefly into nitrous oxide and water. Ammonium nitrate has a typical salt action and may be used as an ingredient of diuretic mixtures. Like the nitrates of sodium and potassium, it is more irritant than such salts as sodium and potassium chlorides, and it is rarely employed in medicine. It should be administered with care when there is irritation of the stomach or kidneys. Ammonium nitrate in doses of $7\frac{1}{2}$ grains in keratin-coated tablets is given in conjunction with a ketogenic diet with the object of rendering the urine acid in the treatment of chronic coli bacilluria. It is also used for the manufacture of nitrous oxide gas and as a chemical reagent. **Dose.**—0.3 to 1.2 grammes (5 to 20 grains).

SODII NITRAS.—Sodium nitrate, NaNO_3 , is mined in Chili and Peru. After purification, it occurs as colourless, odourless, transparent, rhombohedral crystals, having a cooling, saline, slightly bitter taste. It is soluble in water (1 in 1.1), boiling water (1 in 0.6) and boiling alcohol (1 in 40). Sodium nitrate resembles potassium nitrate in its action. It is rarely used in medicine, but in the crude state it is known as Chili saltpetre and is used as an artificial manure. **Dose.**—0.3 to 1 gramme (5 to 15 grains).

Preparation

Charta Nitrata, B.P.C.—(Charta Nit.)—Nitrated Paper. *Syn*—Saltpetre Paper; Nitre Paper. Blotting paper impregnated with potassium nitrate

POTASSII PERMANGANAS

(Pot. Permang.)

Potassium Permanganate

Potassium permanganate may be obtained by passing carbon dioxide into an aqueous solution of potassium manganate, which is prepared by fusing manganese dioxide with potassium hydroxide. It occurs in dark purple, slender, prismatic, odourless crystals, with a greenish lustre, having a taste at first sweet, but afterwards disagreeable and astringent. When heated, the salt decrepitates at a temperature of about 240° and decomposes, giving off oxygen and leaving a residue from which water extracts potassium hydroxide. The deep purple colour of the aqueous solution is discharged by easily oxidisable substances such as ferrous sulphate, oxalic acid and organic matter, particularly in the presence of sulphuric acid.

Soluble in water (1 in 20) and boiling water (1 in 3).

Standard, B.P.—Potassium permanganate contains not less than 99 per cent. of KMnO_4 . It complies with limit tests for chloride and sulphate.

Action and Uses.—Potassium permanganate possesses disinfectant, deodorant and germicidal properties, owing to its oxidising action in acid, neutral, or alkaline solution. It is occasionally administered as an intestinal antiseptic, but is of doubtful value. Good results are said to have been obtained in acute pneumonia by the rectal administration of 4 fluid ounces of a solution of 2 grains of potassium permanganate in 1½ pints of warm water every three hours. Neurasthenia associated with low blood pressure has been treated by the oral administration of potassium permanganate and thyroid, in cachets or capsules. As a cleansing application to foul ulcers or abscesses, a 1 in 1000 solution is suitable; as a gargle, mouth-wash, or vaginal injection, solutions of 1 in 4000 may be used, and for urethral irrigation in the treatment of gonorrhœa a 1 in 800 solution is used. When applied to the nose and throat, potassium permanganate is particularly useful as a prophylactic of infections due to filterable viruses. A 5 per cent. solution of potassium permanganate has a powerful styptic action. Potassium permanganate is a useful antidote to snake poisoning and also to morphine and opium poisoning. In both cases immediate application is necessary, since its action as an antidote is due to direct oxidation of the poison. In cases of snake poisoning, solid potassium permanganate should be applied freely to the wound before absorption of the toxin has taken place.

Potassium permanganate is usually **administered** in pill form, some inert material such as kaolin and soft paraffin being used to form the mass, without the addition of any oxidisable substance. It may also be administered as *Liquor Potassii Permanganatis*, suitably diluted, although it may cause irritation to the stomach. Solutions of potassium permanganate rapidly stain the skin brown; the stain can be removed from the skin by means of oxalic or sulphurous acids. It is **incompatible** with iodides, reducing agents and most organic substances.

Dose.—0·06 to 0·2 gramme (1 to 3 grains).

Preparation

Liquor Potassii Permanganatis, B.P.C.—(*Liq. Pot. Permang.*)—Solution of Potassium Permanganate. 1 per cent. w/v. Dose.—8 to 15 millilitres (2 to 4 fluid drachms).

This solution was included in the British Pharmacopœia, 1914.

POTASSII PERSULPHAS

(*Pot. Persulph.*)

Potassium Persulphate

Potassium persulphate may be prepared by the electrolysis of a

solution of potassium bisulphate under conditions similar to those described under Ammonii Persulphas. It occurs as colourless crystals or as a white, crystalline powder and has properties similar to those of ammonium persulphate.

Soluble in water (1 in 3); insoluble in dehydrated alcohol.

Standard.—Potassium persulphate, determined by the method for Ammonii Persulphas, contains not less than 98 per cent. of $K_2S_2O_8$; each millilitre of N/10 potassium permanganate is equivalent to 0.01352 gramme of $K_2S_2O_8$.

Action and Uses.—Potassium persulphate has strong oxidising and bleaching properties. It is used as a disinfectant for the hands, to sterilise and bleach sponges, and in photography to reduce dense negatives. Potassium persulphate has been added to flour as an "improver." Bakers using such flour are liable to suffer from a form of dermatitis, commonly known as "baker's eczema" or "baker's itch."

POTASSII PHOSPHAS

(Pot. Phosph.)

Potassium Phosphate

Synonym—Di-potassium Hydrogen Phosphate.

Potassium phosphate may be prepared by mixing phosphoric acid with a sufficient quantity of potassium hydroxide or carbonate to produce a slightly alkaline reaction, filtering and evaporating. It occurs in irregular masses, or as a granular, deliquescent powder. At a red heat it is converted into pyrophosphate.

Very **soluble** in water; insoluble in alcohol.

Standard.—Potassium phosphate, determined by the method of the British Pharmacopœia for Sodii Phosphas, contains not less than 98 per cent. of K_2HPO_4 , calculated on the salt dried at 100° ; each millilitre of N/2 sulphuric acid is equivalent to 0.08711 gramme of K_2HPO_4 . Loss on drying at 100° , not more than 5 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies with the limit tests for chlorides, sulphates and calcium and magnesium in Sodii Phosphas.

Action and Uses.—Potassium phosphate is a saline purgative resembling sodium phosphate in its action.

Dose.—0.6 to 2 grammes (10 to 30 grains).

POTASSII PHOSPHAS ACIDUS

(Pot. Phosph. Acid.)

Potassium Acid Phosphate

Synonyms—Potassium Di-hydrogen Phosphate; Potassium Biphosphate.

Potassium acid phosphate, KH_2PO_4 , may be prepared by treating 100 parts of phosphoric acid (25 per cent.) with 35 parts of dried potassium carbonate, adding to the solution a further 100 parts of the acid and evaporating. It occurs in the form of large, colourless, quadratic crystals. It is not decomposed at a temperature of 200° , but at a red heat it loses one molecule of water and yields potassium metaphosphate, KPO_3 .

Very **soluble** in water, the solution having an acid reaction.

Standard.—Potassium acid phosphate, determined by the method of the British Pharmacopœia for Sodii Phosphas Acidus, contains not less than 97 per cent. of KH_2PO_4 ; each millilitre of N/2 sodium hydroxide is equivalent to 0.06807 gramme of KH_2PO_4 . Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. 1 gramme dissolved in 50 millilitres of water requires for neutralisation to the green colour of bromocresol green, indicative of pH 4.5, not more than 1.0 millilitre of N/10 sulphuric acid (limit of dipotassium phosphate). It complies with the limit tests for chlorides and sulphates in Sodii Phosphas Acidus.

Action and Uses.—Potassium acid phosphate has properties resembling those of sodium acid phosphate and is used to render the urine acid. It is a somewhat more active diuretic than the sodium salt, and is best **administered** in dilute aqueous solution, in small doses frequently repeated.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

POTASSII QUADROXALAS

(Pot. Quadroxal.)

Potassium Quadroxalate

Synonyms—Sal Acetosella; Potassium Tetroxalate; Salt of Sorrel; Sal Limonis; Salts of Lemon.

Potassium quadroxalate, $\text{KHC}_2\text{O}_4, \text{H}_2\text{C}_2\text{O}_4, 2\text{H}_2\text{O}$, may be prepared by mixing hot, concentrated, aqueous solutions of potassium oxalate and oxalic acid in the required proportions. It occurs in colourless, transparent crystals and has an acid taste.

Soluble in water (1 in about 30), boiling water (1 in about 2).

Action and Uses.—Potassium quadroxalate is not used medicinally, but is solely employed for removing ink stains and iron mould from clothing and table-linen, and for cleaning white straw hats. It is sometimes used mixed with cream of tartar. In cases of **poisoning** by potassium oxalates, the procedure adopted under Acidum Oxalicum should be followed.

POTASSII BINOXALAS.—Potassium binoxalate is potassium acid oxalate, $\text{KHC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, and is found in various species of *Oxalis* and *Rumex*. It may be prepared by partly neutralising a solution of oxalic acid with the required quantity of potassium carbonate. It occurs in colourless crystals and has an acid taste. The anhydrous salt and a tetrahydrate are also known. This salt was sold as salts of lemon but is now replaced for this purpose by potassium quadroxalate. Its aqueous solution is unstable below 50° and decomposes with the formation of the less soluble potassium quadroxalate. It is soluble in water (1 in 5 at 60°).

POTASSII OXALAS.—Potassium oxalate, $\text{K}_2\text{C}_2\text{O}_4$, is the neutral salt and occurs in colourless crystals soluble in water. This neutral oxalate is added to blood to precipitate calcium and prevent coagulation.

POTASSII SALICYLAS

(Pot. Salicyl.)

Potassium Salicylate

Potassium salicylate, $\text{C}_6\text{H}_4(\text{OH}) \cdot \text{COOK}$, may be obtained by treating a hot solution of salicylic acid with potassium bicarbonate or potassium carbonate until only very faintly acid, filtering, and evaporating to dryness. It occurs as brilliant, colourless, silky needles, or as a white powder. When heated at 210° to 220° , it decomposes quantitatively into dipotassium *p*-hydroxybenzoate, phenol and carbon dioxide, but in the presence of excess of potassium hydroxide this change does not take place. When treated with bromine and an excess of potassium hydroxide, it yields a red substance, insoluble in alcohol and ammonia.

Soluble in water and alcohol.

Standard.—Potassium salicylate, determined by the method of the British Pharmacopœia for Sodii Salicylas, contains not less than 98 per cent. of $\text{C}_7\text{H}_5\text{O}_3\text{K}$, calculated on the substance dried at 110° ; each millilitre of $\text{N}/2$ sulphuric acid is equivalent to 0.08807 gramme of $\text{C}_7\text{H}_5\text{O}_3\text{K}$. Loss on drying at 110° , not more than 1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies with the limit tests for chlorides and sulphates in Sodii Salicylas.

Action and Uses.—Potassium salicylate closely resembles sodium salicylate in its action, and is employed similarly for oral administration.

Dose.—0.6 to 2 grammes (10 to 30 grains).

POTASSII SULPHAS

(Pot. Sulph.)

Potassium Sulphate*Synonym*—Sal Polychrestum.

Potassium sulphate may be obtained by the interaction of sulphuric acid and potassium carbonate. It occurs in colourless, transparent, hard, rhombic prisms, terminated by six-sided pyramids, or as a white powder, having a somewhat bitter, saline taste. When heated it decrepitates. At a bright red heat it fuses, and at a white heat it is partially decomposed.

Soluble in water (1 in 10), boiling water (1 in 4); insoluble in alcohol.

Standard.—Potassium sulphate, determined by the method of the British Pharmacopœia for Sodii Sulphas, contains not less than 99 per cent. of K_2SO_4 ; 1 gramme of BaSO_4 is equivalent to 0.7467 gramme of K_2SO_4 . Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. 0.3 gramme complies with the limit test for chlorides. 1 gramme dissolved in 50 millilitres of water forms a solution which is not acid to methyl orange (absence of acid sulphate). .1 gramme warmed with 10 millilitres of water does not produce a blue colour on the addition of dilute solution of ammonia (limit of copper), and the solution gives no precipitate on the addition of hydrogen sulphide solution (limit of zinc). 1 gramme dissolved in 20 millilitres of water gives no precipitate when boiled with 1 millilitre of dilute solution of ammonia (limit of aluminium and iron).

Action and Uses.—Potassium sulphate is a saline purgative resembling sodium sulphate in its action. It is said to enhance anæsthesia when added to some local anæsthetics (0.25 to 0.5 per cent.). Potassium sulphate is **administered** in mixture form, freely diluted, since strong solutions are irritating to the stomach and intestines.

Dose.—1 to 3 grammes (15 to 45 grains).

POTASSII TARTRAS

(Pot. Tart.)

Potassium Tartrate*Synonym*—Normal Potassium Tartrate.

Potassium tartrate, $(\text{K}_2\text{C}_4\text{H}_4\text{O}_6)_2\text{H}_2\text{O}$, may be obtained by neutralising potassium acid tartrate with potassium carbonate. It occurs in small, colourless, translucent, four or six-sided prisms, or as a white, crystalline, slightly deliquescent powder, with a saline, cooling taste. When

heated, it chars and gives off inflammable vapours having the odour of burnt sugar. At a higher temperature, the carbon is burned off and a white fused mass of potassium carbonate remains.

Soluble in water (1 in 0.25); insoluble in alcohol.

Standard.—Potassium tartrate, determined by the method of the British Pharmacopœia for Sodii et Potassii Tartras, contains not less than 99 per cent. of $C_8H_8O_{12}K_4, H_2O$; each millilitre of N/2 sulphuric acid is equivalent to 0.05881 gramme of $C_8H_8O_{12}K_4, H_2O$. Arsenic limit, 2 parts per million. Lead limit, 20 parts per million. 0.5 gramme complies with the limit tests for chlorides and sulphates. Dissolve 2 grammes in 40 millilitres of water and 5 millilitres of dilute solution of ammonia; no darkening occurs on the addition of 1 drop of sodium sulphide solution (limit of copper and iron). Dissolve 1 gramme in 10 millilitres of water; the solution is not alkaline to phenolphthalein, and requires not more than 0.1 millilitre of N/10 sodium hydroxide to produce a pink colour (limit of alkali and of free acid).

Action and Uses.—Potassium tartrate is a typical saline purgative. The tartrates of the alkalis are less readily absorbed than the citrates; their purgative action is therefore more marked, whilst their action as diuretics and as antacids in rendering the urine alkaline is less pronounced. Potassium tartrate is **administered** in mixture form, well diluted.

Dose.—2 to 16 grammes ($\frac{1}{2}$ to 4 drachms).

POTASSII TARTRAS ACIDUS

(Pot. Tart. Acid.)

Potassium Acid Tartrate

Synonyms—Cream of Tartar; Purified Cream of Tartar.

Potassium acid tartrate, $COOH \cdot (CHOH)_2 \cdot COOK$, is obtained from crude cream of tartar, or argol, which is deposited from grape juice during fermentation and is found also in the lees of wine; it may also be obtained from tartaric acid by precipitation with potassium carbonate. It occurs as colourless and odourless, slightly opaque crystals, or as a white, gritty, crystalline powder, with a pleasant, acidulous taste. The aqueous solution has an acid reaction.

Soluble in water (1 in 220), boiling water (1 in 16); insoluble in alcohol (90 per cent.).

Standard, B.P.—Potassium acid tartrate contains not less than 99.5 per cent. of $C_4H_5O_6K$, calculated on the substance dried at 100° . Loss on drying at 100° , not more than 1 per cent. Arsenic limit, 2 parts per million. Lead limit, 20 parts per million. It complies also

with limit tests for copper and iron, free tartaric acid, chloride and sulphate.

Action and Uses.—Potassium acid tartrate has an action identical with that of potassium tartrate. It is employed as a laxative in combination with sulphur or jalap as *Confectio Sulphuris* and *Pulvis Jalapæ Compositus*. *Potus Imperialis* is an agreeable cooling and diuretic drink in febrile conditions.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

POTASSII BOROTARTRAS.—Potassium borotartrate occurs usually in colourless scales and is soluble in its own weight of water; it is obtained by dissolving 5 parts of potassium acid tartrate and 2 parts of borax in water with the aid of heat, and evaporating the solution to dryness.

Preparation

Potus Imperialis, B.P.C.—(*Potus Imperial.*)—Imperial Drink. *Syn.*—*Haustus Imperialis*. Potassium acid tartrate, 0·45 per cent. w/v, with citric acid, sucrose, oil of lemon and tincture of lemon, in distilled water; each fluid ounce contains 2 grains of potassium acid tartrate.

PROCAINÆ HYDROCHLORIDUM

(*Procaïn. Hydrochlor.*)

Procaine Hydrochloride

Synonym—Ethocaine Hydrochloride.

Procaine hydrochloride is the hydrochloride of diethylaminoethyl-*p*-aminobenzoate, $\text{NH}_2\cdot\text{C}_6\text{H}_4\cdot\text{COO}\cdot\text{C}_2\text{H}_4\text{N}(\text{C}_2\text{H}_5)_2$, which may be prepared by the action of diethylaminoethylchloride on sodium *p*-aminobenzoate. It occurs as a stable, white, odourless, crystalline powder, with a faintly bitter taste, followed by a temporary insensibility of the tongue. A 10 per cent. w/v aqueous solution is neutral to litmus, and is not precipitated by the addition of sodium bicarbonate. On the addition of a solution of sodium hydroxide or sodium carbonate, a colourless, oily precipitate of the base is produced which becomes crystalline on standing. The base crystallises from dilute alcohol with two molecules of water, and melts at about 51° ; when recrystallised from light petroleum it is anhydrous and has a melting-point of 58° to 60° . When a 1 in 50 aqueous solution, containing a trace of hydrochloric acid and of sodium nitrite, is added to a solution of betanaphthol in dilute sodium hydroxide solution, a scarlet precipitate is produced.

Procaine hydrochloride may be distinguished from cocaine hydrochloride by adding to a 1 in 50 aqueous solution, acidified with two or three drops of dilute sulphuric acid, a few drops of $\text{N}/10$ potassium permanganate solution; the permanganate solution is immediately decolourised. It may be distinguished from orthocaine by the formation

of a precipitate on the addition of solution of iodine, and on the addition of potassio-mercuric iodide solution, the latter reaction also serving to distinguish it from benzocaine. The aqueous solution may be boiled without decomposition in alkali-free glass vessels.

Soluble in water (1 in 1) and alcohol (90 per cent.) (1 in 8); slightly soluble in chloroform; insoluble in ether.

Standard, B.P.—Procaine hydrochloride has a melting-point of 154° to 156°. Ash, not more than 0·1 per cent. It complies also with a limit test for readily carbonisable substances.

Action and Uses.—Procaine hydrochloride is a local anæsthetic resembling cocaine in its action, but is less toxic and less irritating. It is, moreover, the most widely used of the synthetic substitutes for cocaine. Procaine hydrochloride has little power of penetration, and is not satisfactory for surface anæsthesia. When injected, its action is rapid and moderately powerful, but somewhat transitory; to obtain a prolonged and intense anæsthetic effect it is therefore usual to add a small proportion of adrenaline, with the object of delaying dispersion from the site of injection. With this addition, solutions of procaine hydrochloride are regarded as equivalent in activity to cocaine solutions of the same strength.

Solutions containing 5 per cent. w/v are isotonic with blood serum; weaker solutions require the addition of a suitable proportion of sodium chloride. For infiltration and anoci-association anæsthesia, 0·25 to 0·5 per cent. w/v solutions are employed, for nerve trunks, 1 or 2 per cent. w/v solutions, and for intraspinal anæsthesia, a 5 per cent. w/v solution. To increase the specific gravity of procaine hydrochloride solutions for intraspinal injection, 5 per cent. w/v of dextrose may be added. For dental use, a 2 per cent. w/v solution is employed in doses of 1 millilitre (15 minims), with 0·06 millilitre (1 minim) of 1 in 1000 solution of adrenaline hydrochloride. In ophthalmic surgery, 5 and 10 per cent. w/v solutions are used; they exert no mydriatic effect. Solutions with adrenaline frequently darken in colour. Care should be taken to avoid injecting procaine hydrochloride into a vein, since toxic effects have been observed from its inadvertent intravenous injection. The toxic action of procaine hydrochloride may be reduced by a preliminary dose of phenobarbitone or other barbiturate. Constant wetting of the skin with solutions of procaine hydrochloride causes, in some individuals, a dermatitis characterised by dryness and cracking of the skin. Solutions of procaine hydrochloride for **injection** may be sterilised by tyndallisation or by filtration. The containers must comply with the tests for limit of alkalinity of glass, and the solutions should be stored protected from light. In cases of **poisoning** by procaine hydrochloride, hot coffee and stimulants should be administered and the usual methods adopted to prevent collapse.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains); up to 1 gramme (up to 15 grains), by subcutaneous injection; up to 0·15 gramme (up to 2 $\frac{1}{2}$ grains), by intrathecal injection.

PROFLAVINA

(Proflavin.)

Proflavine

Proflavine is 2:8-diaminoacridine sulphate, and is obtained as an intermediate product in the preparation of acriflavine. It is an orange-red to brownish-red crystalline powder. An aqueous solution, when freely diluted, has a pronounced greenish fluorescence. An aqueous solution yields a precipitate on the addition of formaldehyde and gives the reactions characteristic of sulphates.

Soluble in water (about 1 in 200).

Standard.—Proflavine, determined by the method for Euflavina, contains not less than 97 per cent. of $\text{C}_{13}\text{H}_{11}\text{N}_3\cdot\text{H}_2\text{SO}_4$, calculated on the substance dried at 100° ; each millilitre of M/10 potassium ferricyanide is equivalent to 0.09216 gramme of $\text{C}_{13}\text{H}_{11}\text{N}_3\cdot\text{H}_2\text{SO}_4$. Loss on drying at 100° , not more than 10 per cent. Sulphated ash, not more than 1 per cent. 0.5 gramme dissolves completely in 250 millilitres of 0.9 per cent. solution of sodium chloride, and the solution remains bright when kept for twelve hours in the dark.

Action and Uses.—Proflavine is an efficient antiseptic for wounds because it acts in the presence of an excess of serum. It, therefore, possesses advantages over such substances as mercuric chloride, which lose most of their activity in the presence of proteins. Proflavine acts in concentrations much lower than those which inhibit phagocytosis and produce irritation. A solution of proflavine, 1 in 150,000, will kill *Staphylococcus aureus* in serum in forty-eight hours, whereas a solution of mercuric chloride, 1 in 20,000, is necessary for the same purpose. The flavine compounds cannot, however, produce a rapid disinfectant action except in high concentrations. Proflavine may be used in solutions of similar strength to those of acriflavine. It is also used as a urinary antiseptic in the treatment of gonorrhœa, both as a lotion and by oral administration; damage to the kidneys and liver may occur and it should be **administered** internally with great caution. Proflavine stains may be removed by the application of a dilute solution of sulphurous acid. Solutions for **injection** may be prepared by aseptic methods. They should be stored protected from light.

HOMOFLAVINA.—Homoflavine is the hydrochloride of 3:7-dimethyl-2:8-diamino-10-methylacridinium chloride. In its chemical and general properties it is closely related to acriflavine.

PRUNUS

(Prun.)

Prune

Prune is the dried, ripe fruit of *Prunus domestica* Linn. var. *Juliana*

DC. (Fam. Rosaceæ), cultivated in France. The fruit is collected when ripe, and dried partly by artificial heat and partly in the sun.

The fruit is an irregularly flattened, ovoid drupe, about 3 centimetres long, purplish-black in colour, and with a shrivelled surface. The pulp is brownish, and surrounds a hard, flattened, oval stone. The pulp of prune **contains** from 23 to 56 per cent. of invert sugar, together with malic and citric acids, a little fat and pectin.

Action and Uses.—Prune is nutritious and demulcent, and is employed for its laxative action in the preparation of confection of senna and other laxative confections.

CERASUS.—The red cherry is the fruit of *Prunus Cerasus* Linn. var. *capromiana* DC. (Fam. Rosaceæ), a tree bearing sessile umbels each consisting of a few white flowers on long pedicels; it is cultivated in England. The fruit is a red, globose, fleshy drupe, glabrous and destitute of bloom, about 2 centimetres in diameter, and having a firmly attached, slender peduncle. The mesocarp has an acid taste and the seed is enclosed in a smooth, somewhat flattened, stony endocarp. The black cherry, obtained from *Prunus avium* Linn., is slightly larger, dark purple in colour and has a sweet taste. Cherries contain about 6 to 9 per cent. of sugar (invert sugar and sucrose), organic acids (chiefly malic and citric acids), pectin, colouring matter, etc. The juice of the red cherry is employed as a flavouring and colouring agent and in the preparation of syrup of cherry.

Preparation

Syrupus Cerasi, B.P.C.—(Syr. Ceras.)—Syrup of Cherry. A solution of sucrose in the juice expressed from red cherry. Dose.—2 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

PRUNUS SEROTINA

(Prun. Serot.)

Wild Cherry Bark

Synonyms—Pruni Virginianæ Cortex; Prunus Virginiana.

Wild cherry bark is the bark of the wild or black cherry, *Prunus serotina* Ehrhardt (Fam. Rosaceæ), a tree widely distributed over North America, particularly in the Northern and Central States. The bark is collected in the autumn, when it is most active, preferably from young stems and branches, and dried.

The bark occurs in irregular fragments, or in curved or channelled pieces up to 12 centimetres in length and 5 centimetres in width and about 2 millimetres in thickness. The young bark is covered externally with a thin, smooth, reddish-brown to brownish-black, papery cork, which is frequently exfoliated, disclosing the smooth, greenish-brown cortex; both the cork and the underlying cortex show numerous, transversely elongated lenticels. Older bark is darker and rougher. The inner surface is cinnamon-brown in colour, and shows fine, wavy, longitudinal striations, which anastomose to form a projecting reticulation. The fracture is short and granular. The smoothed, transversely

cut surface is reddish-grey in colour, and usually shows numerous pale red, medullary rays, alternating with phloem strands containing sclerenchymatous tissue which, on the inner margin, projects beyond the medullary rays. The drug has a slight odour and an astringent, aromatic, bitter taste recalling that of bitter almond.

The diagnostic **microscopical** characters are the numerous sclerenchymatous cells, usually in groups, and often branched; the absence of typical phloem fibres; the minute starch grains in the parenchyma; near the sclerenchyma, the prismatic crystals and occasional cluster-crystals of calcium oxalate.

Wild cherry bark **contains** *d*-mandelonitrile glycoside (prunasin) and an enzyme, which interact in the presence of water and yield benzaldehyde, hydrocyanic acid and dextrose. Benzoic, trimethylgallic and *p*-coumaric acids and a small amount of essential oil are present. Other constituents are tannin, a phytosterol, fatty acids, and resinous substances which yield β -methylxsculetin on hydrolysis with acid. Good specimens of drug yield from 0.075 to 0.16 per cent. of hydrocyanic acid. It yields to alcohol (60 per cent.) from 17 to 23 per cent. of extractive. The ash is about 3 to 4 per cent., and the acid-insoluble ash from 0.2 to 0.6 per cent. Young bark is more active than the thick bark from old stems.

Substitutes.—A form of the bark, known as “rossed” bark, sometimes occurs in commerce; this consists of bark from which the cortex, in addition to the cork, has been removed; its uniformly dark cinnamon-brown outer surface has a rough or rasped appearance, and exhibits under a lens pale, longitudinal strands of sclerenchymatous cells alternating with darker medullary rays. Barks from other species of *Prunus* are occasionally substituted for the official drug and may be recognised by the presence of fibres or by their astringent taste, which is deficient in the flavour of bitter almond. Old bark shows numerous depressions on the outer surface, and no lenticels.

Standard, B.P.—Wild cherry bark contains not more than 2 per cent. of other organic matter. The thickness of the bark does not exceed 3 millimetres.

Wild cherry bark, in powder (*Pulvis Pruni Serotinæ*; *Pulv. Prun. Serot.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Preparations of wild cherry bark are used to relieve the cough in phthisis, bronchitis, etc. The mildly sedative property is generally credited to the small quantity of hydrocyanic acid present. It is **administered** as *Syrupus Pruni Serotinæ* or as *Tinctura Pruni Serotinæ*.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparations

Syrupus Pruni Serotinæ, B.P.—(*Syr. Prun. Serot.*)—Syrup of Wild Cherry.

Syn.—*Syrupus Pruni Virginianæ*; Syrup of Virginian Prune. A solution of sucrose in the liquid obtained by percolating wild cherry bark with glycerin and water; it contains active constituents equivalent to 15 per cent. w/v of the bark. It should be stored in well-closed containers in a cool place. Dose.—2 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms)

Tinctura Pruni Serotinæ, B.P.C.—(Tinct. Prun. Serot.)—Tincture of Wild Cherry. *Syn.*—Tinctura Pruni Virginianæ; Tincture of Virginian Prune. 1 in 5. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopæia, 1914, under the name of Tinctura Pruni Virginianæ.

PSYLLIUM

(Psyll.)

Psyllium

Synonym—Flea Seed.

Psyllium consists of the dried, ripe seeds of *Plantago Psyllium* Linn. and of *P. arenaria* Waldst. and Kit. (Fam. Plantaginaceæ), annual herbs which are natives of Barbary and Southern Europe.

The seeds of *P. Psyllium* are about 2 to 3 millimetres long and 0·8 to 1·2 millimetres wide, rounded-oblong in outline, dark reddish brown, and with a shining, glossy surface. They are very transparent and show the embryo as a paler, longitudinal patch, about one-third the width of the seed as seen through the outer layers. In the centre of the concave surface is the pale-coloured hilum; across the centre of the convex surface is a slight transverse constriction. The embryo and endosperm are similar to those of the seeds of ispaghula. When soaked in water, the seeds become surrounded by a layer of colourless, transparent mucilage. The seeds of *P. arenaria* closely resemble those of *P. Psyllium*, but are more elliptical in outline; they are blackish-brown in colour and not very transparent; the surface is rather dull. They are from 2 to 2·5 millimetres long and 1 to 1·5 millimetres wide at the centre; the furrow of the concave surface frequently extends to the extreme end of the seed.

The diagnostic **microscopical** characters of psyllium are similar to those of ispaghula, but the epidermis does not split away from the remainder of the seed as it does in ispaghula.

Psyllium **contains** mucilage as its principal constituent, and also fixed oil and proteins. It yields about 2·5 to 4 per cent. of ash.

Substitute.—The seeds of *Plantago lanceolata* Linn. are distinguished by their yellowish-brown colour, the dark furrow with a black, central hilum and the failure to produce any appreciable layer of mucilage when soaked in water. One hundred seeds weigh about 0·16 gramme.

Standard.—Psyllium contains not more than 3 per cent. of foreign organic matter. One hundred seeds weigh not less than 0·09 gramme and not more than 0·13 gramme. 1 gramme, agitated gently and occasionally during twenty-four hours in a 25 millilitre stoppered cylinder filled to the 20 millilitre mark with water, and allowed to stand for one hour, occupies a volume of not less than 12 millilitres.

Psyllium, in powder (Pulvis Psyllii : Pulv. Psyll.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Psyllium, on account of its content of mucilage, is used as a demulcent. It has the property of absorbing and retaining water and is therefore used as a bulk-providing medium in the treatment of chronic constipation. For this reason, psyllium is administered as an alternative to agar or linseed. The average dose is from two to four tablespoonfuls taken with a draught of water. The correct amount for the individual case can only be ascertained by experience. It has also been used in industry as a dressing for linen.

PTEROCARPUS

(*Pterocarp.*)

Red Sanders Wood

Synonyms—*Pterocarp*i Lignum; Red Sandal Wood; Ruby Wood.

Red sanders wood is the heartwood of *Pterocarpus santalinus* Linn. (Fam. Leguminosæ), a small tree indigenous to Southern India and the Philippine Islands. The wood is imported in irregular logs or billets, 7 to 15 centimetres thick and about 1 metre long, which have been deprived of their bark and pale sapwood.

The heartwood is of a deep purplish-red colour and very hard, heavy and fibrous, but easily splits longitudinally. The smoothed, transversely cut surface shows an absence of annual rings, but exhibits darker tangential bands of dense wood fibres alternating with narrow, paler, interrupted bands of wood parenchyma, on the inner borders of which are found the diffusely arranged vessels; very fine, pale medullary rays cross these bands at right angles and are only just visible at a magnification of about 10 diameters. For pharmaceutical use the wood is generally obtained as a coarse powder or in small, hard, splintery raspings. The wood imparts a blood-red colour to alcohol, but yields hardly anything to water. It is almost odourless, and has a somewhat astringent taste.

The diagnostic **microscopical** characters are the thick-walled, strongly lignified fibres, more or less cylindrical in the middle part but with thin tapering ends; the medullary rays, which are about 7 to 9 cells high and usually uniseriate, a few being biseriate in the middle part; the large vessels with closely approximated, slit-like bordered pits; the prismatic crystals of calcium oxalate in the parenchyma bordering upon the fibres. All the cell walls are brownish-red, and the cells are filled with masses of reddish-brown resin; the red colour is removed by warming with solution of chloral hydrate.

Red sanders wood **contains** the red colouring matters, santalin (santalic acid) and deoxysantalin. Santalin is insoluble in water, but yields a blood-red solution with alcohol, yellow with ether, and violet with ammonia and caustic alkalis. The wood also contains santal, pterocarpin and homopterocarpin, three colourless, crystalline substances. It yields from 1 to 2 per cent. of ash.

Standard.—Red sanders wood yields to alcohol (95 per cent.) not less than 20 per cent. of extractive.

Uses.—Red sanders wood is employed solely for its colouring matter, which is precipitated by mineral acids.

PULSATILLA

(*Pulsat.*)

Pulsatilla

Synonym—Pasque Flower.

Pulsatilla consists of the dried herb, *Anemone Pulsatilla* Linn. (Fam. Ranunculaceæ), a plant indigenous to Great Britain, Europe and Siberia.

The herb possesses a stout, somewhat woody rhizome producing a rosette of stalked leaves and an erect scape, about 12 to 20 centimetres long, bearing a whorl of three bracteoles which form an involucre about 2 to 3 centimetres below the large, solitary, terminal flower. The leaves are tripinnate, the ultimate lobes being linear with acute points, and the petioles often purplish. The sessile bracteoles are divided to the base into linear segments, and the flower possesses six light purple sepals, silky on the outside. The fruits are small, brown, hairy achenes with feathery styles about 3·5 centimetres long. The whole plant, especially the bases of the petioles, is covered with silky hairs. The taste of the fresh herb is acrid and burning, but is less conspicuous in the dried herb and gradually diminishes on keeping; the drug is odourless.

The herb **contains** a crystalline, vesicant substance (anemone camphor) which is soluble in ether and chloroform and gives off an intensely irritating vapour. It slowly decomposes into anemonin and isoanemonic acid, the change taking place more rapidly in the presence of water. Anemonin is crystalline, tasteless and odourless when pure, and melts at about 152°; it is volatile in steam. isoAnemonic acid is crystalline and tasteless.

Substitute.—*Anemone pratensis* Linn. possesses smaller, blackish-purple flowers with the tips of the segments bent backwards. This species is used in homœopathic practice.

Standard.—Pulsatilla contains not more than 3 per cent. of foreign organic matter.

Action and Uses.—Pulsatilla has been employed for use in dysmenorrhœa and amenorrhœa, and for the relief of headache and neuralgia, but there is no reliable evidence of its value. It is **administered** as Extractum Pulsatillæ Liquidum or Tinctura Pulsatillæ, and as Liquor Caulophylli et Pulsatillæ or Liquor Caulophylli et Pulsatillæ Compositus.

Preparations

Elixir Euonymi et Pulsatillæ, B.P.C.—(Elix. Euonym. et Pulsat.)—Elixir of Euonymus and Pulsatilla. Tincture of euonymus and tincture of pulsatilla, of each 1 in 8, in simple elixir. Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

Extractum Pulsatillæ Liquidum, B.P.C.—(Ext. Pulsat. Liq.)—Liquid Extract of Pulsatilla. 1 in 1. Dose.— 0·12 to 0·3 millilitre (2 to 5 minims).

Liquor Caulophylli et Pulsatillæ, B.P.C.—(Liq. Cauloph. et Pulsat.)—Solution of Caulophyllum and Pulsatilla. Liquid extract of caulophyllum, 1 in 4, and liquid extract of pulsatilla, 1 in 20, with glycerin and alcohol (60 per cent.). Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Liquor Caulophylli et Pulsatillæ Compositus, B.P.C.—(Liq. Cauloph. et Pulsat. Co.)—Compound Solution of Caulophyllum and Pulsatilla. Liquid extracts of caulophyllum, about 1 in 6, pulsatilla, 1 in 20, aletris, 1 in 10, and black haw, 1 in 5, with glycerin and alcohol (60 per cent.). Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Tinctura Pulsatillæ, B.P.C.—(Tinct. Pulsat.)—Tincture of Pulsatilla. Liquid extract of pulsatilla, 1 in 10. Dose.— 0·3 to 2 millilitres (5 to 30 minims).

PYRETHRI FLOS

(Pyreth. Flos)

Pyrethrum Flower

Synonyms—Insect Flowers; Dalmatian Insect Flowers.

Pyrethrum flower consists of the dried flowerheads of *Chrysanthemum cinerariæfolium* Vis. (Fam. Compositæ), a herbaceous perennial indigenous to Montenegro, Dalmatia and the adjacent coastal islands, and cultivated in those countries and also in Japan, Germany, Great Britain and elsewhere. Pyrethrum flower should be **stored** in closed, well-filled containers, and should not be kept for more than two years.

The capitula occur loose or compressed into masses, the individual capitula being more or less flattened, about 6 to 12 millimetres in diameter, and commonly having a short piece of stalk attached. The receptacle is usually about 5 to 10 millimetres in diameter; it is destitute of paleæ and almost flat, and is surrounded by an involucre of 2 or 3 rows of brownish-yellow, lanceolate bracts. The ray florets number about 15 to 23, and the disc florets about 200 to 300. The ligulate corollas are pale brownish and shrivelled, each being oblong in shape, about 16 millimetres long, and showing three rounded, apical teeth, the central one frequently being smaller in size than the lateral ones; there are about 17 veins in the middle region of the corolla. Each disc floret has a yellow, tubular corolla with 5 short lobes at the summit. All the florets have an inferior, 5-ribbed, oblong cypsela, about 5 millimetres long and surmounted by a membranous, tubular calyx about 1 millimetre in length. The ovaries and lower part of the corollas are covered with numerous, scattered, shining oil glands. The drug possesses a faint but characteristic odour and a slightly bitter taste.

The diagnostic **microscopical** characters are the loose, large-celled,

lignified, moderately thick-walled and pitted parenchyma of the receptacle; the numerous spiny pollen grains, each with 3 pores and measuring about 25 to 28 microns in diameter; the frequent, ovoid-spherical, glandular trichomes, each consisting of 3 or 4 tiers of 2 cells each; the twisted, T-shaped balance-hairs and lignified tissue from the involucre bracts; the fragments of the ray florets, showing cells of the lower epidermis with wavy walls, and of the upper epidermis with puckered papillæ; fragments of the lobes of disc florets; portions of stigmas with papillose tips, and, from the cypselæ, portions of brown resin canals and sclerenchyma, the cells of which contain diamond-shaped crystals as also do the cells of the epidermis.

Pyrethrum flower **contains** pyrethrin I and pyrethrin II, to which it owes its insecticidal properties. These pyrethrins are esters of a keto-alcohol, pyrethrolone, and chrysanthemum monocarboxylic acid and chrysanthemum dicarboxylic acid respectively; they are both soluble in alcohol, benzene, chloroform and light mineral oils, easily hydrolysed by weak alkalis, and decomposed by heat and light. The combined content of the pyrethrins varies from about 0.4 to 2.0 per cent., of which over 90 per cent. is contained in the cypselæ, a little in the involucre and stem, and only traces in the corollas. They are generally present in approximately equal amounts, larger proportions of pyrethrin II being occasionally found. A small amount of volatile oil is also present.

Varieties.—Dalmatian insect flowers are classed as “closed,” “half-closed,” and “open,” and are loosely packed. Those imported from Japan are firmly compressed and include flowers in all stages of development. The “closed” variety of the flowers was formerly considered superior, but it has been shown that fully open flowers, not over-blown and from which the cypselæ have not been lost, contain a larger percentage of the pyrethrins.

Substitutes.—The dried flowerheads of *Ch. roseum* Adam, from the Caucasus, and of *Ch. Marshallii* Aschers, from Persia, having red flowers, are occasionally met with in commerce. They have more than 20, generally nearly 30, ray florets. The flowerheads of *Ch. Leucanthemum* Linn. are sometimes substituted for pyrethrum flower; they are distinguished by the entire absence of calyx or pappus, by the three teeth terminating the strap of the somewhat lanceolate, ligulate corolla, the central teeth being usually the largest, and by the presence of only 7 veins in the strap.

Standard.—Pyrethrum flower contains not less than 0.4 per cent. of pyrethrin I. Ash, not more than 8 per cent. Acid-insoluble ash, not more than 1 per cent.

Pyrethrum flower, in powder (*Pulvis Pyrethri Floris* : *Pulv. Pyreth. Flor.*), contains the constituents and possesses the diagnostic microscopical characters of *Pyrethri Flos*, and complies with the standard for the unground drug.

Assay.—Extract 10 grammes, in No. 85 powder, in a continuous extractor with light petroleum (boiling-range, 40° to 50°). Pour the light petroleum solution, which should be adjusted to approximately 50 millilitres, into the long-necked flask of a micro-Kjeldahl apparatus and rinse the extraction flask with a little light petroleum. Add 5 millilitres of N/1 sodium hydroxide in methyl alcohol, and reflux the

mixture vigorously on a water-bath for two hours. Cool, acidify with N/1 sulphuric acid, and distil in a current of steam until 150 millilitres of aqueous distillate is collected below the light petroleum in the receiver. Transfer the whole to a separator, washing the flask with 20 millilitres of water and then with 10 millilitres of light petroleum. Add 10 grammes of sodium chloride and shake vigorously. After separation, run off the aqueous layer into a second separator and shake with a further 20 millilitres of light petroleum. Repeat the shaking with 20 millilitres of light petroleum, mix the three light petroleum layers, and wash the mixture with three successive portions of water. Transfer the light petroleum to a stoppered bottle, rinse the separator with 10 millilitres of neutral alcohol, adding the rinsings to the contents of the bottle, and rinse the separator with 20 millilitres of water. Add 2 or 3 drops of phenolphthalein solution and titrate with N/50 sodium hydroxide until the aqueous layer shows a distinct pink colouration after vigorous shaking in the stoppered bottle for at least one minute. Deduct the volume of N/50 sodium hydroxide required in a blank experiment on the light petroleum (usually about 0.2 millilitre), and calculate the percentage of pyrethrin I; each millilitre of N/50 sodium hydroxide is equivalent to 0.0066 gramme of pyrethrin I.

Action and Uses.—Pyrethrum flower in powder is used to stupefy and keep away insects. For this purpose it is often mixed with borax or boric acid. It is also employed as an insecticide and insect repellent in the form of an extract diluted with kerosene and used as a spray. Tinctura Pyrethri Floris is used, diluted with 10 parts of water, as an application to the skin to prevent insect bites.

Preparation

Tinctura Pyrethri Floris, B.P.C.—(Tinct. Pyreth. Flor.)—Tincture of Pyrethrum Flower. 1 in 4.

PYRETHRI RADIX

(Pyreth. Rad.)

Pyrethrum Root

Synonyms—Pellitory Root; Spanish Pellitory.

Pyrethrum root is the root obtained from *Anacyclus Pyrethrum* DC. (Fam. Compositæ), a small plant indigenous to Algeria. It is collected in the autumn and dried.

The root is brown, deeply wrinkled longitudinally, cylindrical or somewhat fusiform; it varies from 7 to 15 centimetres in length, is usually unbranched, and frequently shows remains of leaves or a tuft of greyish hairs at the crown which is 10 to 20 millimetres thick. The fracture is short, the smoothed, transverse surface being radiate and showing narrow, yellowish wedges of xylem alternating with wide, whitish medullary rays. Numerous yellow or brown resin glands are

visible in the bark and medullary rays. It has a slight aromatic odour; the taste is characteristically astringent, and the root, when chewed, excites a flow of saliva.

The diagnostic **microscopical** characters are the tabular cork cells, many of which are developed as sclerenchyma; the pitted vessels of the xylem, measuring up to 40 or 50 microns in cross section; the schizogenous oleo-resin glands of the phloem and medullary rays; the presence of inulin and the absence of starch and of calcium oxalate.

Pyrethrum root **contains** a colourless, crystalline acid amide, pellitorine (pyrethrine), $C_{14}H_{25}ON$, which possesses an intensely pungent taste and produces the sialagogue effect; it also contains about 50 per cent. of inulin, hydrocarotin and traces of volatile oil. It yields to alcohol (70 per cent.) about 14 per cent. of extractive.

Substitute.—Sarghine, the root of *Corrigiola littoralis* Linn. (Fam. Illecebraceæ), is sometimes substituted for pyrethrum root. It may be distinguished by the small warty protuberances with which it is crowned, and by the section, which exhibits three or four concentric circles. It is devoid of pungency, but one variety has a phenolic odour resembling that of iodoform.

Standard.—Pyrethrum root yields not more than 7 per cent. of ash.

Pyrethrum root, in powder (Pulvis Pyrethri Radicis : Pulv. Pyreth. Rad.), contains the constituents and possesses the diagnostic microscopical characters of Pyrethrum Radix, and complies with the standard for the unground drug.

Action and Uses.—Pyrethrum root has sialagogue properties and is used to promote salivary effusion in dryness of the mouth and throat. The tincture is applied on cotton wool or rubbed along the gums in toothache, and for this purpose may with advantage be mixed with camphorated chloroform. Pyrethrum root is **administered** in the form of lozenge, pastille (containing 1 grain in each), or tincture.

Preparation

Tinctura Pyrethri, B.P.C.—(Tinct. Pyreth.)—Tincture of Pyrethrum. 1 in 5.

This tincture was included in the British Pharmacopœia, 1914.

PYRIDINA

(Pyrid.)

Pyridine

Pyridine is a heterocyclic compound which occurs, together with certain homologues, in the products of the destructive distillation of nitrogenous organic matter. It may be separated from bone oil (Dippel's Oil) or from coal tar by extraction with dilute mineral acids. Pyridine occurs as a colourless, volatile liquid, having a peculiar, unpleasant odour and a bitter taste. Specific gravity, about 0.98; boiling-point,

about 115° . It is a weak tertiary base; its aqueous solution is alkaline to litmus, but does not affect phenolphthalein. It combines with acids to form crystalline salts such as the hydrochloride, $C_5H_5N \cdot HCl$, and with methyl iodide to form the quaternary ammonium derivative. It has the property of forming double salts with certain metals, especially the chlorides of copper, mercury, zinc and cadmium. With picric acid solution it forms a yellow, crystallisable picrate. In chemical behaviour it resembles benzene, but is more resistant to substitution. Three isomeric mono-substitution products are obtainable (α , β and γ), and by reduction with nascent hydrogen it is converted into piperidine.

Crude pyridine for use in denaturing alcohol requires for neutralisation not less than 9.5 times its volume of N/1 sulphuric acid, using congo-red paper as indicator. When distilled under the conditions laid down for motor fuel, it should give a distillate of at least 50 per cent. v/v at 140° , and of 90 per cent. v/v at 160° ; it must comply also with certain limit tests for colour and solubility, and respond to prescribed identity tests.

Miscible with water, alcohol, ether, chloroform, benzene and fixed oils.

Action and Uses.—Pyridine and similar compounds are amongst the products of the dry distillation or slow combustion of most leaves, and to pyridine has been ascribed in part the beneficial action of the various burning-powders and cigarettes used in asthma. It apparently acts as a depressant to the nerve endings in the bronchioles. It is much less toxic than either collidine or nicotine, which are given off with pyridine from burning tobacco. Crude pyridine is used as a denaturant in the manufacture of methylated spirits.

PIPERIDINA.—Piperidine, or hexahydropyridine, $C_5H_{11}N$, is prepared by the dry distillation of piperine, or by the reduction of pyridine. It occurs as a colourless, limpid liquid, having an ammoniacal and peppery odour and a burning, caustic taste. Specific gravity, about 0.881; boiling-point, about 106° . It is a strongly basic secondary amine and yields crystalline salts with acids. It is miscible with water, alcohol and ether. Piperidine has a weak, coniine-like action, but is rarely used in medicine.

PIPERIDINÆ TARTRAS.—Piperidine tartrate, $C_5H_{11}N \cdot C_4H_6O_6$, occurs in the form of a colourless, crystalline powder, having a faint odour and a pleasant taste. It is readily soluble in water. Piperidine tartrate has been employed as a uric acid solvent in gout and rheumatism, but its value for this purpose is doubtful. It may be administered in cachets or mixtures. Dose.—0.6 to 1 gramme (10 to 15 grains).

PYROGALLOL

(Pyrogall.)

Pyrogallol

Synonym—Pyrogallic Acid.

Pyrogallol is 1:2:3-trihydroxybenzene, $C_6H_3(OH)_3$, and may be

obtained by the action of heat on gallic acid. It occurs in light, white and feathery, or dense, hard crystals, which sublime on heating and become discoloured on exposure to light and air. A solution of pyrogallol gives a blue colour with solution of ferrous tartrate, and a red colour with solution of ferric chloride. Alkaline solutions of pyrogallol rapidly turn black in contact with air owing to the absorption of oxygen. The alkaline solution absorbs oxygen quantitatively. It should be **stored** in well-closed, amber-coloured bottles, and not exposed to light.

Soluble in water (1 in 2), freely soluble in alcohol and ether.

Standard.—Pyrogallol melts between 129° and 135°. Ash, not more than 0.1 per cent. The solution in water is clear, colourless or slightly yellow, and neutral to methyl orange.

Action and Uses.—Pyrogallol, when taken internally, exerts a toxic action on the blood; methæmoglobin is formed, passes into the plasma, and leaves the red corpuscles as granular debris; jaundice and acute nephritis may follow, hence it is now very rarely given internally. It is employed topically as a parasiticide and mildly irritant ointment in chronic skin diseases such as psoriasis, lupus vulgaris and ringworm, but it is not suitable for continuous application over large areas or denuded surfaces, since absorption and consequent poisoning may result. In psoriasis, Unguentum Pyrogallolis, often diluted with 1 to 5 parts of soft paraffin, is used, and Unguentum Pyrogallolis Compositum is employed in psoriasis and chronic eczema. Jarisch's ointment is composed of 60 grains of pyrogallol in 1 ounce of lard. A powder composed of pyrogallol, 1 part, and starch, 4 parts, has been applied to phagedenic chancres. Pyrogallol has the disadvantage of staining the skin and hair black. Stains upon the skin may be removed with ammonium persulphate. Pyrogallol is an ingredient of hair dyes, usually with silver nitrate or copper chloride; it is largely used as a developer in photography.

ACIDUM PYROGALLICUM OXIDATUM.—Oxidised pyrogallol is prepared by the action of air and ammonia on pyrogallol. It occurs as a dark brown powder which is slightly soluble in water, but insoluble in dehydrated alcohol and ether. It has been used, generally in the form of an ointment, plaster, or soap, as a substitute for pyrogallol, since it is less liable to set up inflammation or to cause toxic effects from absorption; it does not blacken the skin. Eye drops containing 1 in 200 to 1 in 1000 have been used with success in chronic conjunctivitis.

Preparations

Unguentum Pyrogallolis, B.P.C.—(Ung. Pyrogall.)—Pyrogallol Ointment. *Syn.*—Unguentum Acidi Pyrogallici; Pyrogallic Acid Ointment. Pyrogallol, 12.5 per cent., in white soft paraffin.

Unguentum Pyrogallolis Compositum, B.P.C.—(Ung. Pyrogall. Co.)—Compound Ointment of Pyrogallol. *Syn.*—Unguentum Acidi Pyrogallici Compositum; Compound Pyrogallic Acid Ointment; Unna's Compound Pyrogallol Ointment. Pyrogallol and ichthammol, of each 5 per cent., and salicylic acid, 2 per cent., in yellow soft paraffin.

PYROXYLINUM

(Pyroxylin.)

Pyroxylin

Pyroxylin is a nitrated cellulose prepared from defatted cotton wool by treatment with a mixture of nitric and sulphuric acids. It occurs as a white, felted mass of filaments, somewhat similar in appearance to cotton wool but harsher to the touch. It is highly inflammable. The properties of a nitrated cellulose are dependent upon the number of nitro-groups introduced into the cellulose molecule and this, in turn, is dependent upon the composition and concentration of the acids used in its preparation, the temperature, and the period during which the nitration is allowed to proceed. Slight differences in the conditions may result in a marked alteration in the viscosity of a collodion prepared from the resulting pyroxylin. In expressing the composition of nitrated cellulose, the cellulose molecule is usually given the arbitrary formula, $C_{12}H_{20}O_{10}$. On this notation, pyroxylin has approximately the composition of a cellulose tetranitrate, $C_{12}H_{16}O_6(ONO_2)_4$, and is completely soluble in a mixture of alcohol and ether. Nitrated celluloses containing more than 5 or less than $3\frac{1}{2}$ nitro-groups are incompletely soluble or insoluble in mixtures of alcohol and ether. Gun-cotton, which is cellulose hexanitrate, $C_{12}H_{14}O_4(ONO_2)_6$, may thus be distinguished from pyroxylin. Pyroxylin should be **stored** loosely packed, in a cool place, and protected from light. It may be kept moistened with industrial methylated spirit.

Soluble in a mixture of 1 volume of alcohol (90 per cent.) and 3 volumes of ether, yielding an almost clear and colourless solution; also soluble in acetone.

Standard, B.P.—Pyroxylin contains not less than 11.5 per cent. and not more than 12.3 per cent. of nitrogen, calculated on the dry substance. Viscosity at 20° of a 3 per cent. w/v solution of the dry substance in acetone, not less than 3 poises.

Action and Uses.—Pyroxylin is employed in the preparation of collodions and similar rapid-drying, protective varnishes. Collodium Acetonom, Collodium Flexile and Collodium Simplex are useful applications for chilblains, small cuts and abrasions, and as vehicles for the application of drugs such as salicylic acid, when prolonged action is required.

Preparations

Collodium Acetonom, B.P.C.—(Collod. Aceton.)—Acetone Collodion. Pyroxylin, 1 in 20, and oil of clove, in amyl acetate, benzene and acetone.

Collodium Flexile, B.P.—(Collod. Flex.)—Flexible Collodion. *Syn.*—Collodion. Pyroxylin, 2 per cent. w/v, with colophony and castor oil in alcohol (90 per cent.) or industrial methylated spirit suitably diluted, and ether.

Collodium Simplex, B.P.C.—(Collod. Simp.)—Simple Collodion. Pyroxylin, about 1 in 50, in ether and alcohol (90 per cent.).

This collodion was included in the British Pharmacopæia, 1914, under the name of Collodium.

QUASSIA

(Quass.)

Quassia

Synonyms—Quassiæ Lignum; Quassia Wood.

Quassia is the stem-wood of *Picræna excelsa* (Sw.) Lindl. (Fam. Simarubaceæ), a moderate-sized tree indigenous to Jamaica, and known in commerce as Jamaica quassia. The trunks and larger branches with the bark attached are exported in logs, which, for medicinal use, are freed from the bark, cut into chips, and dried.

Quassia occurs either in logs or, more usually, in chips or raspings. The wood has a density of about 0.54 to 0.56; it is yellowish-white or sometimes bright yellow, and tough, but easily split longitudinally, the grain being straight. The smoothed and moistened transverse surface, examined under a lens, shows numerous, narrow medullary rays, about 6 to 8 per millimetre of arc, traversing the diffuse porous wood, which is composed chiefly of fibres and parenchyma in interrupted tangential bands; true annual rings are absent. The drug is odourless and has an intensely bitter taste.

The diagnostic **microscopical** characters are the vessels with very numerous, minute bordered pits; the wood fibres with moderately thick, obliquely pitted walls; the wood-parenchyma, occurring mainly in interrupted tangential bands; the medullary rays, mostly two or three cells wide; the large, single, prismatic crystals of calcium oxalate in certain cells, both of the parenchyma and of the medullary rays; the presence of not more than a few starch grains, about 4 to 12 microns in diameter, mostly simple and spherical, or occasionally compound, with two components.

Quassia **contains** two homologous, crystalline, bitter principles, α -picrasmin and β -picrasmin (see Quassinum). The wood also contains a very small quantity of a third crystalline, bitter principle (melting-point, 234°), and a minute quantity of a yellow, crystalline substance which exhibits a blue fluorescence in an acidified alcoholic solution. Quassia yields to water from 4.5 to 6.5 per cent. of extractive.

Substitutes.—Surinam quassia, from *Quassia amara* Linn., is distinguished by the medullary rays which are mostly one cell wide and by the absence of calcium oxalate. Exhausted quassia may be differentiated by the lower yield of aqueous extractive and by the less bitter taste. Quassia wood showing greyish patches is wood which has been attacked by fungus.

Standard, B.P.—Quassia contains not more than 2 per cent. of foreign organic matter.

Quassia, in powder (Pulvis Quassiæ : Pulv. Quass.), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Quassia is a non-astringent bitter. It is employed to increase the appetite. An infusion (1 in 20) is used as a rectal injection for thread-worms. Infusions are also employed as lotions for pediculosis. Quassia is best **administered** as an infusion,

thirty minutes before a meal. The tincture and extract are sometimes prescribed, the latter in pills. On account of its freedom from tannin, quassia may be given with salts of iron. A strong infusion of quassia painted on the skin keeps away small insects. Concentrated extracts, or preparations containing quassin, are also used as denaturants for alcohol, and, in conjunction with soft soap, as insecticides in horticulture.

Dose.—0.12 to 0.5 gramme (2 to 8 grains).

QUASSINUM.—Quassin, or picrasmin, may be obtained by exhausting quassia with 50 per cent. alcohol, neutralising with magnesia, making the solution acid with tartaric acid and removing the alcohol by distillation. The residue is shaken with chloroform, the solution evaporated to a syrupy consistence and the residue dissolved in dehydrated alcohol. The concentrated alcoholic solution is covered with a layer of ether, set aside to crystallise and the product recrystallised from alcohol. It is mainly a mixture of two homologous, crystalline, bitter principles, α -picrasmin, which melts at 204°, and β -picrasmin, which melts at from 209° to 212°. Quassin occurs in the form of white, odourless, crystalline needles or prisms. It has an extremely and persistently bitter taste. Quassin yields picramic acid on hydrolysis with hydrochloric acid. It may be removed from acid solutions by shaking with chloroform or benzene, but is not precipitated by lead acetate. Tannic acid precipitates the quassin from an alcoholic solution. It is soluble in water (about 1 in 1200), easily soluble in alcohol, soluble in chloroform (about 1 in 2) and benzene, slightly soluble in ether and light petroleum, soluble in caustic alkalis and in acid liquids. The bitter principle of *Quassia amara* is closely allied to, but not identical with, the quassin of *Picræna excelsa*; like the latter, it is a mixture of homologous, crystalline, bitter principles and yields quassic acid on hydrolysis with hydrochloric acid. A purified extract in the form of an amorphous, granular, sticky powder, yellowish-brown in colour, is also known commercially as quassin or dry extract of quassia.

Preparations

Extractum Quassiæ, B.P.C.—(Ext. Quass.)—Extract of Quassia. A soft extract. Dose.—0.2 to 0.3 gramme (3 to 5 grains).

Infusum Quassiæ Concentratum, B.P.—(Inf. Quass. Conc.)—Concentrated Infusion of Quassia. Quassia, 1 in 12½, extracted with cold distilled water and preserved with alcohol. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of quassia, and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

A concentrated infusion, prepared with dilute chloroform water and alcohol (90 per cent.), was included in the British Pharmaceutical Codex, 1923.

Infusum Quassiæ Recens, B.P.—(Inf. Quass. Rec.)—Fresh Infusion of Quassia. 1 in 100. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

Tinctura Quassiæ, B.P.—(Tinct. Quass.)—Tincture of Quassia. 1 in 10, by maceration in alcohol (45 per cent.). Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

QUEBRACHA

(Quebrach.)

Quebracho

Synonyms—Aspidosperma; Quebracho-blanco; White Quebracho.

Quebracho is the dried bark of *Aspidosperma Quebracho* Schlecht.

(Fam. Apocynaceæ), a large evergreen tree indigenous to the dry central and western districts of the Argentine and adjacent regions.

The bark occurs in nearly flat or slightly curved pieces about 6 to 18 centimetres long and 3 to 7 centimetres broad, and varying in thickness from 1.5 to 3 centimetres. The outer surface is reddish-brown or ashen, and has the appearance of being divided into roughly quadrangular, pentagonal, or hexagonal, very rugged islets, separated from one another by deep fissures; an occasional small group of lichens may be found attached to the bark, which also shows numerous minute, glistening points which are crystals of calcium oxalate. The inner surface is coarsely striated longitudinally, and varies in colour from light to dark brown, but it may sometimes be yellowish-white or occasionally of a rose-pink shade. The smoothed, transversely cut surface shows two sharply defined strata of about equal thickness, both of which are marked with numerous light-coloured dots and several tangential striæ; the fracture of the outer, brownish-coloured layer of rhytidome is rather coarsely granular, while that of the inner layer, which is of similar colour to the inner surface, is short and splintery. The drug has no odour, but a very bitter and somewhat aromatic taste.

The diagnostic **microscopical** characters are the large, isolated phloem fibres, about 0.5 to 1.2 millimetres long and 40 to 115 microns wide, each surrounded by a crystal sheath, giving the appearance of an incrustation, with prisms of calcium oxalate; the starch grains found throughout the parenchyma of the bark, mostly having 2 to 4 components, individual granules being up to 25 microns in diameter; the groups of stone cells from the phloem and medullary rays and the abundant cork cells.

Quebracho **contains** the alkaloids, aspidospermine, yohimbine (quebrachine), and quebrachamine. It also contains starch, tannin, quebrachitol and inositol.

Action and Uses.—Quebracho is a bitter and has been given as a tonic and febrifuge. It has a marked stimulant action on the respiratory centre in the medulla, and has been used in dyspnoea associated with cardiac or pulmonary disease; large doses may cause nausea and vomiting. It is usually **administered** in the form of tincture; a liquid extract (1 in 1) has also been prepared.

QUERCUS

(*Querc.*)

Oak Bark

Oak bark consists of the dried bark obtained from the smaller branches and young stems of the British oak, *Quercus Robur* Linn. and *Quercus sessiliflora* Salisb. (Fam. Fagaceæ), and is collected in the spring from trees growing in Great Britain.

The bark occurs in pieces about 25 millimetres wide, 2 millimetres thick and of varying length; the outer surface bears a glossy and silvery-grey cork, marked with occasional, faint, transverse, whitish lenticels, rarely bearing lichens. The inner surface is light brown to brownish-red, dull and coarsely striated. The fracture is fibrous. The smoothed transverse section, viewed under a lens, shows a thin cork or rhytidome, a narrow brownish cortex, a line of pericyclic fibres and stone cells, and, in the secondary phloem, delicate, tangential lines of sclerenchymatous fibres alternating with soft bast. The bark is without odour, and the taste is sweetish and afterwards astringent.

Oak bark **contains** 15 to 20 per cent. of quercitannic acid, $C_{17}H_{16}O_9$. It also contains a phlobaphene, oak red, which is produced from quercitannic acid by treatment with dilute sulphuric acid and may be regarded as its anhydride; gallic acid, ellagic acid, quercitol, lævulin, phloroglucinol and starch are also present.

Action and Uses.—Oak bark has astringent properties, but is now rarely used in medicine. It is sometimes employed as Decoctum Quercus as a rectal injection for hæmorrhoids and as a gargle for sore throats.

Preparation

Decoctum Quercus, B.P.C.—(Dec. Querc.)—Decoction of Oak Bark. About 1 in 15.

QUILLAIA

(Quill.)

Quillaia

Synonyms—Quillaia Cortex; Quillaia Bark; Soap Bark; Panama Bark.

Quillaia consists of the dried, inner part of the bark of *Quillaja Saponaria* Molina, a tree indigenous to Chile and Peru, and cultivated in India, and of other species of *Quillaja* (Fam. Rosaceæ).

Quillaia occurs in hard, tough, flat pieces up to about 1 metre in length, 10 to 15 or more centimetres in width and 3 to 10, usually about 6, millimetres thick. The outer surface is brownish-white, and bears occasional reddish or blackish-brown streaks or patches where the rhytidome has been incompletely removed; it is longitudinally striated or marked with a coarse, whitish reticulation. The inner surface is yellowish-white, smooth and very hard. The fracture is coarse and splintery, the fractured surface showing an evident lamination; numerous glistening, prismatic crystals of calcium oxalate are freely sprinkled upon the laminæ, and some are also visible upon the inner surface. The smoothed, transversely cut surface has a chequered appearance formed by alternating tangential bands of phloem parenchyma and phloem fibres across which run the radial medullary rays; the innermost layer appears more or less homogeneous. The drug is

odourless, but is strongly sternutatory when powdered; it has an acrid, astringent taste. The powdered drug forms a persistent froth when shaken with water.

The diagnostic **microscopical** characters are the bundles of phloem fibres, which are tortuous and irregularly enlarged at intervals; the occasional sub-rectangular sclereids; the abundant starch grains up to 20 microns, usually 5 to 10 microns, in diameter; the large crystals of calcium oxalate up to 170 microns long and up to 30 microns wide; the small amount of red-brown cork cells with red-brown contents.

Quillaia **contains** two colourless, amorphous, toxic glycosides, quillaic acid and quillaia-sapotoxin. These principles belong to the class of saponins (see Saponinum); they both impart to water the property of frothing, but the acrid taste and sternutatory effect are due to quillaia-sapotoxin alone. The bark also contains sucrose. It yields to alcohol (45 per cent.) from 30 to 40 per cent. of extractive.

Varieties.—The bark of *Quillaja Saponaria* shows externally longitudinal streaks and occasional patches of reddish-brown rhytidome; the bark said to be derived from *Q. Poeppigii* Walp. is usually thinner than the foregoing and is marked externally with a coarse, whitish reticulation; a thick bark, apparently from a species of *Quillaja*, is found in commerce and is very much thicker and somewhat softer in texture than that of *Q. Saponaria*.

Standard, B.P.—Quillaia contains not more than 2 per cent. of foreign organic matter. Ash, not more than 15 per cent.

Quillaia, in powder (Pulvis Quillaie : Pulv. Quill.), contains the constituents and possesses the diagnostic microscopical characters of Quillaia, and complies with the limit for ash of the unground drug.

Action and Uses.—Quillaia is an expectorant and, in large doses, an emetic, but is rarely given internally. Preparations of quillaia are employed for washing the skin and the scalp in the treatment of pediculosis. Tincture of quillaia is used as an emulsifying agent, especially for tar preparations and for small quantities of volatile oils. The powdered bark acts as a powerful sternutatory.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

Preparations

Extractum Quillaie Liquidum, B.P.C.—(Ext. Quill. Liq.)—Liquid Extract of Quillaia. 1 in 1.

Tinctura Quillaie, B.P.—(Tinct. Quill.)—Tincture of Quillaia. 1 in 20, by percolation with alcohol (45 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

QUINETUM

(Quinet.)

Quinetum

Quinetum, as defined by the Malaria Commission of the League of Nations in 1931, is a mixture of equal parts of quinine, cinchonidine

and cinchonine, these being approximately the relative proportions in which these alkaloids are present in the total alkaloids of red cinchona bark. It occurs as a white powder, which may show traces of crystalline structure, and gives off alkaline fumes when strongly heated. The name quinetum was originally used as a synonym for "cinchona febrifuge," which then consisted of the total alkaloids of the bark of *Cinchona succirubra*. With the gradual replacement of *C. succirubra* by species of *Cinchona* yielding bark richer in quinine, both quinetum and cinchona febrifuge have changed in character. Modern cinchona febrifuge consists of residual alkaloids left after the removal of the bulk of the quinine from the total alkaloids of those types of cinchona bark used for the manufacture of quinine sulphate. It varies greatly in composition and physical characters. The Malaria Commission of the League of Nations recommended that in countries where cinchona febrifuge is at present manufactured or used, the competent authority should bring the product to the totaquine standard by the addition of suitable amounts of crystalline cinchona alkaloids.

Partly **soluble** in ether, chloroform and cold alcohol; completely soluble in boiling alcohol and in acids.

Standard.—Quinetum, determined by the method of the British Pharmacopœia for Totaquina, yields not less than 60 per cent. of quinine and cinchonidine. Loss on drying at 100°, not more than 5 per cent. Ash, not more than 1 per cent.

Action and Uses.—Quinetum is administered by the mouth in the treatment of benign and malignant tertian malaria. It was introduced as a substitute for quinine, upon which to a great extent its action depends, and is superior to the more variable cinchona product known as "cinchona febrifuge."

Dose.—0·06 to 0·6 gramme (1 to 10 grains).

QUINIDINA

(Quinidin.)

Quinidine

Quinidine is an alkaloid, isomeric with quinine, obtained from the bark of many species of *Cinchona*. It occurs to the extent of about 0·2 per cent. in average stem and branch barks, but a somewhat higher proportion is found in root barks. It may be obtained from the mother liquors resulting from the manufacture of quinine sulphate by precipitating the alkaloids with sodium hydroxide, extracting with ether, shaking out the ethereal solution with dilute sulphuric acid, neutralising with sodium hydroxide and finally adding tartaric acid until no further precipitate is produced. The crude bitartrate of quinidine is further

purified by recrystallising from water, after decolourising with charcoal if necessary, and is then dissolved in water and the quinidine precipitated by ammonia, washed, and dried at a temperature of about 30°. The quinidine alkaloid so obtained is usually practically free from all the other cinchona alkaloids except hydroquinidine, a closely allied base of very similar chemical, physical and physiological properties, which is usually present to the extent of about 20 to 30 per cent.

Quinidine occurs as a white, amorphous powder or as acicular crystals, without odour, but having a very bitter taste. Its melting-point is about 168°. Its solutions in acids or organic solvents are dextro-rotatory. Its solution in dilute sulphuric acid is fluorescent, and it yields a green colour when a slightly acid solution is treated with bromine followed by ammonia solution. Neutral solutions give a precipitate of sparingly soluble hydriodide on the addition of potassium iodide solution.

Almost **insoluble** in water (1 in 2000); soluble in alcohol (90 per cent.) (1 in 17) and ether (1 in 70). When anhydrous, it dissolves in about 1·6 parts of chloroform.

Standard.—Quinidine loses, on drying at 100°, not more than 10 per cent. of its weight. Ash, not more than 0·1 per cent. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 0·05 gramme dissolved in 1 millilitre of sulphuric acid produces not more than a pale yellow colour (limit of readily carbonisable substances). When 0·5 gramme is neutralised with sulphuric acid and sufficient water added to produce 15 millilitres, the resulting solution complies with the limit test for other cinchona alkaloids in Quinidinæ Sulphas.

Action and Uses.—The action of quinidine in most respects resembles that of quinine; its depressant action on the heart, however, limits its use to some extent. It is said to be particularly active against the benign tertian form of malaria, although many authorities do not agree on this point. It is remarkable for its action upon the muscles of the auricles, and is consequently used for the control of auricular fibrillation; quinidine sulphate is generally administered for this purpose.

Dose.—0·2 to 0·6 gramme (3 to 10 grains)

QUINIDINÆ SULPHAS

(Quinidin. Sulph.)

Quinidine Sulphate

Quinidine sulphate is the sulphate of the alkaloid, quinidine, found in the bark of various species of *Cinchona*. It occurs in the form of white,

acicular crystals, neutral or faintly alkaline to litmus, without odour, but having an intensely bitter taste. It becomes darker in colour on exposure to light. One molecule of water of crystallisation is lost at 100°, the second being lost at 120°. The dry salt re-absorbs two molecules of water on exposure to the air. The dilute aqueous solution acidified with sulphuric acid shows a strong blue fluorescence. Quinidine sulphate may be distinguished from the sulphates of most other alkaloids by the gradual formation of a white precipitate, soluble in nitric acid, on the addition of silver nitrate solution to a saturated aqueous solution. An emerald-green colouration is produced when the aqueous solution is treated with bromine water and dilute solution of ammonia as described under Quinina. Quinidine sulphate may be distinguished from quinine sulphate by the dextrorotation of its aqueous solution, and by the formation of a white precipitate on the addition of a solution of potassium iodide. It should be **stored** in well-closed containers and protected from light.

Soluble in water (about 1 in 90) and alcohol (90 per cent.) (1 in 10).

Standard, B.P.—Quinidine sulphate loses, on drying at 120°, not more than 5 per cent. of its weight. Ash, not more than 0.04 per cent. It complies also with a test for the absence of inorganic salts and other alkaloids, and with limit tests for readily carbonisable substances and other cinchona alkaloids.

Action and Uses.—Quinidine sulphate is employed in the treatment of auricular fibrillation. In this condition the auricles cease to contract rhythmically, and the auricular musculature is in a state of inco-ordinate and purposeless twitching. Consequently the ventricles do not receive the normal stimuli and they respond by rapid and irregular contractions; the cardiac output is thereby considerably diminished. Quinidine acts by prolonging the refractory period and by reducing the rate of conduction of impulses in the auricles. It tends to increase the ventricular rate by partial paralysis of the vagus. The rhythm of auricular fibrillation can be successfully altered in about 50 per cent. of cases by the administration of quinidine sulphate. In cases of congestive heart failure, digitalisation should precede the use of quinidine. Quinidine sulphate is most efficacious in the prevention of paroxysmal fibrillation and in early persistent fibrillation, as in cases with a toxic or infective origin such as Grave's disease and rheumatic fever; in cases of long standing, and those due to degenerative changes, its effect is doubtful. When fibrillation ceases, which may occur suddenly, the dose should be reduced, and when discontinued, a further course of digitalis should be administered. It may also be of value in auricular flutter and may prove beneficial in preventing and relieving paroxysmal tachycardia.

Occasionally quinidine produces unpleasant symptoms such as palpitation, headache, nausea, vomiting, dizziness, dimness of vision, scarlatiniform eruptions and precordial pain. It should be withheld when there is a history of embolism, or where there is cardiac hypertrophy, especially enlargement of the left ventricle or heart block.

Before a course of treatment is commenced, a preliminary dose of 0.3 gramme (5 grains) should be given; if there are no signs of idiosyncrasy, two doses can be given on the second day, and the number of doses should be increased in this way until the full dose of 2 grammes (30 grains) or more each day is being administered. If there is no improvement after treatment for ten days, quinidine should be discontinued since it is unlikely to be of any benefit. The change to normal rhythm occurs suddenly, and the dose should then be reduced gradually. It may be necessary to continue with daily doses of 0.3 to 0.6 gramme (5 to 10 grains) in order to maintain the normal rhythm. Quinidine sulphate is **administered** in gelatin capsules, in tablets, or in solution, with dilute sulphuric acid if necessary.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

QUININA

(Quinin.)

Quinine

Quinine is the principal alkaloid of various species of *Cinchona*. It may be obtained from the powdered bark, in which it doubtless pre-exists in combination with quinic or cinchotannic acid, by mixing the powder with lime and extracting with alcohol or light petroleum; or by repeatedly boiling the bark with diluted sulphuric or hydrochloric acid and precipitating with solution of ammonia. The precipitate thus obtained is dissolved in 75 or 80 per cent. alcohol, neutralised with dilute sulphuric acid, and the alcohol distilled off. The resulting quinine sulphate, on crystallising, is separated from the mother-liquor, and repeatedly recrystallised from water, whereby the salt is freed from the sulphates of the other alkaloids. The solution of the quinine sulphate in dilute sulphuric acid is precipitated by ammonia, the curdy precipitate of the alkaloid first formed being amorphous and anhydrous, but subsequently changing in presence of ammonia and water into a minutely crystalline state with three molecules of water. It is washed, and dried at a low temperature.

Quinine occurs as a white, soft, flaky or granular powder, or as a microcrystalline powder consisting of minute, four-sided prisms terminated by pyramids, sometimes slightly damp from adhering moisture, without odour and having a bitter taste; it is slightly efflorescent in dry air. Its aqueous solution is laevorotatory, and is alkaline to litmus but not to phenolphthalein. Its solution in dilute sulphuric acid has a strong blue fluorescence, perceptible in a dilution of 1 in 200,000, which is destroyed by the halogen acids, thiosulphates and other substances. Quinine is a strong base, having an alkaline reaction in aqueous and alcoholic

solutions, neutralising the strongest acids and forming neutral and acid salts which for the most part crystallise well, their solutions tasting intensely bitter. At ordinary temperatures it gradually loses one molecule of water of crystallisation, and becomes anhydrous on standing over sulphuric acid. When anhydrous it melts at about 174° . On evaporating a chloroform solution and drying the residue at 100° , the anhydrous base is obtained. Quinine reacts with the usual alkaloidal reagents. The addition of 2 or 3 millilitres of bromine solution, followed by 1 millilitre of dilute solution of ammonia, to 1 millilitre of a 1 per cent. aqueous solution containing sufficient sulphuric acid to dissolve the base, produces an emerald-green colour. When 0.7 gramme is dissolved in a mixture of 15 millilitres of acetic acid, 6 millilitres of alcohol and 0.5 millilitre of sulphuric acid, the solution heated to boiling, and 7 millilitres of a saturated solution of iodine in alcohol added slowly, bronze or olive-green crystals of quinine iodosulphate separate on gradually cooling the solution; the crystals formed are insoluble in cold water. On heating with glycerin to about 180° , it is converted into the isomeric base, quinicine, which is amorphous and dextrorotatory. When quinine and its salts are examined for other cinchona alkaloids by the method of the British Pharmacopœia, accurate results may not be obtained unless the test is applied carefully and all the conditions closely observed.

Slightly **soluble** in water; soluble in alcohol (1 in 1), ether (1 in 4), chloroform (1 in 3), carbon disulphide, benzene, volatile and fixed oils, diluted acids, solution of ammonia, and to some extent in glycerin.

Standard.—Quinine loses, on drying at 100° , not more than 15 per cent. of its weight. Ash, not more than 0.05 per cent. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 0.05 gramme dissolved in 1 millilitre of sulphuric acid or nitric acid is not coloured more than light yellow (limit of readily carbonisable substances). 1.1 grammes, dissolved in 20 millilitres of alcohol (90 per cent.), complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininae Hydrochloridum, commencing with the words "add 20 millilitres of water and 1 millilitre of a 0.02 per cent. w/v solution of methyl red. . . ."

Action and Uses.—Quinine is a general protoplasmic poison and in sufficient concentration paralyses all forms of living matter. It is destructive to fresh-water amœbæ and spermatozoa, inhibits fermentation and retards the action of many unorganised ferments, such as pepsin and trypsin. It inhibits the action of oxydases, and to this property is attributed the remarkable power of quinine to diminish metabolism. The absorption of food is not affected, but the solids of the urine, and especially its nitrogenous constituents, are greatly reduced. Although protein metabolism is thus diminished, the absorption of oxygen and the elimination of carbonic acid are unaffected; there is therefore assumed to be a conservation in the body of nitrogenous material, which in the ordinary course would be oxidised, and would appear in the solids of the urine. Quinine, after absorption, tends to arrest the amœboid movements of the white blood corpuscles

The use of the drug therefore tends to inhibit the formation of pus, but large doses are necessary to prevent suppuration. Quinine has long been supposed to exert an action on the uterus; large doses slightly increase uterine peristalsis, and it is sometimes used for the induction of labour at term.

Quinine is a specific in malaria. The malarial parasite is more susceptible to the action of quinine at some stages of its existence than at others, and the best results are obtained by the administration of the dose a few hours before the paroxysm, so that, allowing time for absorption, the quinine may be in greatest concentration in the blood at the time of the breaking up of the segmented organism into spores, which is coincident with the onset of fever. Quinine is sometimes used in fevers as an antipyretic; its action in reducing temperature is due to diminished heat production, not to augmented loss of heat. In acute fevers the lessened tissue destruction following the use of quinine is probably as important as the reduction of temperature. Many persons show a marked idiosyncrasy to quinine, and comparatively small doses may produce symptoms of "quinism," including giddiness, headache, humming noises in the ears, with deafness that may last a few hours, disturbances of vision, and sometimes erythematous or urticarial skin eruptions.

Quinine is usually **administered** in the form of the sulphate, hydrochloride, or hydrobromide. On account of its comparative insolubility in water, quinine alkaloid is almost tasteless and may be conveniently swallowed with milk.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

Preparation

Oleinatum Quininæ, B.P.C.—(Oleinat. Quinin.)—Oleinate of Quinine. Quinine, 25 per cent. w/w, dissolved in oleic acid.

QUININÆ ACETYSALICYLAS

(Quinin. Acetylsalicyl.)

Quinine Acetylsalicylate

Quinine acetylsalicylate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, \text{C}_6\text{H}_4(\text{COOH})\text{O}\cdot\text{OC}\cdot\text{CH}_3$, may be prepared by mixing alcoholic solutions of quinine and acetylsalicylic acid. It occurs as a white, crystalline powder. Melting-point, about 157° .

Soluble in water (1 in 330), alcohol (1 in 50) and chloroform (1 in 7); insoluble in ether.

Standard.—Quinine acetylsalicylate yields not less than 63.5 per cent. of anhydrous quinine. Loss on drying at 100° , not more than

Soluble in water (about 1 in 10) and alcohol (90 per cent.) (1 in 23).

Standard, B.P.—Quinine bisulphate loses, on drying at 110° , not more than 24 per cent. of its weight. Ash, not more than 0.04 per cent. It complies also with limit tests for other cinchona alkaloids, and for readily carbonisable substances.

Action and Uses.—Quinine bisulphate has the general properties of quinine and is preferable to quinine sulphate for the preparation of tablets; 5 parts of the bisulphate are equivalent to about 4 parts of the sulphate. Solutions undergo decomposition when heated, and quinine bisulphate is therefore less suitable than the dihydrochloride and the dihydrobromide for the preparation of solutions of quinine for injection.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

QUININÆ CITRAS

(Quinin. Cit.)

Quinine Citrate

Quinine citrate is prepared by dissolving quinine in a hot solution of citric acid in water. It occurs in the form of white, acicular crystals, having only a slightly bitter taste.

Soluble in water (about 1 in 1000), boiling water (about 1 in 35), alcohol (about 1 in 70) and boiling alcohol (about 1 in 12); slightly soluble in chloroform.

Standard.—Quinine citrate, determined by the method for Quininæ Acetylsalicylas, yields not less than 74.5 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 10.5 per cent. Ash, not more than 0.1 per cent. 1.3 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words “add 5 millilitres of dilute solution of ammonia. . . .”

Action and Uses.—Quinine citrate has the general properties of quinine salts. It may be **administered** in the form of effervescent granules or pills, or suspended in water.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

QUININÆ FORMAS.—Quinine formate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2 \cdot \text{CH}_2\text{O}_2 \cdot \text{H}_2\text{O}$, occurs in white, crystalline, silky needles. Melting-point, about 126° . It is soluble in water (1 in 19) and alcohol.

QUININÆ DIHYDROBROMIDUM

(Quin. Dihydrobrom.)

Quinine Dihydrobromide

Synonyms—Quininæ Hydrobromidum Acidum; Quinine Acid Hydrobromide.

Quinine dihydrobromide may be prepared by dissolving quinine in hydrobromic acid. It occurs in the form of yellowish or white, prismatic crystals or powder. The aqueous solution is acid to litmus.

Soluble in cold water (1 in 7); very easily soluble in boiling water and alcohol.

Standard.—Quinine dihydrobromide, determined by the method for Quininæ Acetylsalicylas, yields not less than 59 per cent. of anhydrous quinine. Loss on drying at 100°, not more than 11 per cent. Ash, not more than 0·1 per cent. 1 gramme complies with the limit test for sulphates. 0·2 gramme in 10 millilitres of water produces no turbidity with dilute sulphuric acid (limit of barium). 0·05 gramme dissolved in 1 millilitre of sulphuric acid is not coloured more than light yellow (limit of readily carbonisable substances). 1·7 grammes, shaken in a separator with 50 millilitres of water, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine dihydrobromide has the general properties of quinine salts. On account of its ready solubility, it is suitable for the preparation of solutions for injection in the treatment of malaria. Doses of 0·2 to 0·3 gramme (3 to 5 grains) dissolved in from 30 to 50 minims of sterilised water are injected daily. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The acid salts of quinine when given in pill or capsule form, are more readily soluble in the stomach than the neutral salts. Quinine dihydrobromide is **incompatible** with potassium iodide.

Dose.—0·06 to 0·6 gramme (1 to 10 grains).

Preparations

Syrupus Ferri Bromidi cum Quinina, B.P.C.—(Syr. Ferr. Brom. c. Quinin.)—

Syrup of Ferrous Bromide with Quinine. Quinine dihydrobromide, 2 per cent. w/v, with dilute hydrobromic acid, distilled water and syrup of ferrous bromide; each fluid drachm contains about $1\frac{1}{10}$ grains of quinine dihydrobromide and 4 grains of ferrous bromide. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Syrupus Ferri Bromidi cum Quinina et Strychnina, B.P.C.—(Syr. Ferr.

Brom. c. Quinin. et Strych.)—Syrup of Ferrous Bromide with Quinine and Strychnine. Strychnine, about 0·03 per cent. w/v, and quinine dihydrobromide, 2 per cent. w/v, with dilute hydrobromic acid, distilled water and syrup of ferrous bromide; each fluid drachm contains about $\frac{1}{6}$ grain of strychnine, $1\frac{1}{10}$ grains of quinine dihydrobromide and 4 grains of ferrous bromide. Dose—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

QUININÆ DIHYDROCHLORIDUM

(Quinin. Dihydrochlor.)

Quinine Dihydrochloride

Synonyms—Quininæ Hydrochloridum Acidum; Acid Quinine Hydrochloride; Quinine Acid Hydrochloride; Quinine Bihydrochloride.

Quinine dihydrochloride is the acid hydrochloride of the alkaloid quinine. It may be prepared by crystallisation from a solution of quinine in dilute hydrochloric acid. It occurs as a white, odourless, crystalline powder, with a very bitter taste, and contains the equivalent of about 81 per cent. of anhydrous alkaloid. The aqueous solution shows a blue fluorescence on the addition of dilute sulphuric acid; it is acid to litmus but not to congo-red. It should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 0·6), alcohol (90 per cent.) (1 in 12) and chloroform (1 in 7); insoluble in ether.

Standard, B.P.—Quinine dihydrochloride loses, on drying at 110°, not more than 3 per cent. of its weight. Ash, not more than 0·04 per cent. It complies also with limit tests for readily carbonisable substances, barium, other cinchona alkaloids and sulphate.

Action and Uses.—Quinine dihydrochloride is the salt of quinine which should be used for the preparation of solutions for intravenous or intramuscular injection. Injections of quinine dihydrochloride may be used in malaria, rheumatism, puerperal septicæmia, typhoid fever, or whenever quinine by the mouth causes gastric irritation. For intravenous injection, the strength of the solution should not exceed 2·5 per cent.; for intramuscular injection, solutions containing up to 30 per cent. of the salt are used. Subcutaneous injection is liable to be followed by fibrous induration. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0·06 to 0·6 gramme (1 to 10 grains); 0·3 to 0·6 gramme (5 to 10 grains), by intravenous or intramuscular injection.

QUININÆ DISALICYLOSALICYLAS

(Quinin. Disalicylosalicyl.)

Quinine Disalicylosalicylate

Synonym—Quinine Bisalicylosalicylate.

Quinine disalicylosalicylate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2 \cdot 2\text{C}_6\text{H}_4(\text{COOH}) \cdot \text{O} \cdot \text{CO} \cdot \text{C}_6\text{H}_4(\text{OH})$, may be prepared by stirring a cold solution of 5·16 parts of salicylosalicylic acid in 50 parts of water containing 0·8 part of sodium

hydroxide into a cold solution of 5.48 parts of quinine bisulphate in 50 parts of water. The product is filtered, washed and dried, first at room temperature and then at a temperature gradually rising to, but not exceeding, 60°. It occurs as a white, microcrystalline powder, having only a slightly bitter taste.

Insoluble in water; soluble in alcohol (1 in 0.5) and ether (1 in 5).

Standard.—Quinine disalicylosalicylate, determined by the method for Quininæ Acetylsalicylas, contains not less than 38 per cent. and not more than 40 per cent. of anhydrous quinine. Melting-point, 86° to 88°. 2.5 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine disalicylosalicylate has the properties of quinine and salicylates. It has been recommended as a remedial agent for influenza.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

QUININÆ ET ÆTHYLIS CARBONAS

(Quinin. et Æthyl. Carb.)

Quinine Ethyl Carbonate

Quinine ethyl carbonate, $\text{C}_{20}\text{H}_{23}\text{O}_2\text{N}_2 \cdot \text{CO}_2 \cdot \text{C}_2\text{H}_5$, may be obtained by the interaction of ethyl chlorocarbonate and quinine. It occurs in the form of white, slender, odourless and almost tasteless, crystalline needles, or in masses of silky, acicular crystals which are lighter than quinine sulphate. It darkens on exposure to light. The aqueous solution is slightly alkaline to litmus and, when acidified with sulphuric acid, exhibits a strong blue fluorescence; it gives an emerald-green colour when treated with bromine water and dilute solution of ammonia as described under Quinina. Quinine ethyl carbonate is hydrolysed by boiling dilute acids. When warmed with sodium hydroxide and solution of iodine, the odour of iodoform is evolved. It should be **stored** protected from light.

Slightly **soluble** in water; soluble in alcohol (90 per cent.) (1 in 2), ether and chloroform.

Standard, B.P.—Quinine ethyl carbonate has a melting-point not below 95°. Loss in weight on drying over sulphuric acid for twenty-four hours, not more than 2 per cent. Ash, not more than 0.04 per cent. It complies also with limit tests for chloride and sulphate.

Action and Uses.—Quinine ethyl carbonate, on account of its being almost tasteless, is employed as a substitute for quinine sulphate

or hydrochloride in whooping cough, influenza and malaria, especially in children. Solutions in acid or alcohol are much more bitter than the undissolved substance. It may be **administered** in powders, which are best given in milk or in cachets.

Dose.—0·1 to 1 gramme ($1\frac{1}{2}$ to 15 grains).

QUININÆ ET UREÆ HYDROCHLORIDUM

(Quinin. et Urea. Hydrochlor.)

Quinine and Urea Hydrochloride

Quinine and urea hydrochloride, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, \text{HCl}, \text{CO}(\text{NH}_2)_2, \text{HCl}, 5\text{H}_2\text{O}$, is a compound of quinine hydrochloride and urea hydrochloride. It may be prepared by dissolving 400 parts of quinine hydrochloride in 300 parts of dilute hydrochloric acid of specific gravity 1·06, adding 60 to 61 parts of urea, warming the mixture until dissolved, filtering and crystallising. It occurs as white, odourless crystals or powder, having a bitter taste. Melting-point, about 72° , with loss of water. Its aqueous solution is acid to litmus and gives the thalleoquin reaction. A 0·1 per cent. w/v solution in dilute sulphuric acid shows a blue fluorescence. An equal volume of nitric acid, added to a 50 per cent. w/v aqueous solution of the salt cooled to 0° , produces, on standing, crystalline leaflets of urea nitrate.

Soluble in water (about 1 in 1); freely soluble in alcohol.

Standard.—Quinine and urea hydrochloride, determined by the method for Quininæ Acetylsalicylas, yields not less than 58 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 16·5 per cent. Ash, not more than 0·1 per cent. 0·05 gramme dissolved in 1 millilitre of sulphuric acid is not coloured more than light yellow (limit of readily carbonisable substances). 1·7 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine and urea hydrochloride is employed as a local anæsthetic. When injected hypodermically, the solution produces a marked anæsthetic action which is said to be equal to that produced by cocaine but more lasting, and may persist from four hours to several days. This renders it of particular value in operations on the anus and rectum, where the post-operative pain is often considerable. Anæsthesia may occur in from six to ten minutes, although sometimes as long as half an hour may elapse before the full effect is produced. Solutions of 0·5 to 1 per cent. w/v are employed; stronger solutions are liable to retard healing, owing to the formation

of fibrous tissue, and also to cause sloughing. In major operations on the abdominal region, large quantities of 0·2 to 0·5 per cent. w/v solution are used to infiltrate the nerves throughout the whole area of operation, and so produce complete nerve-block, preventing overstimulation of the higher nerve centres and averting the onset of surgical shock. This is known as Crile's method of anoci-association.

The deep intramuscular injection of 5 millilitres (75 minims) of a 1 per cent. w/v solution in the centre of the painful area has given rapid relief and apparent cure in acute lumbago. The same method of treatment has been used with success in the treatment of sciatica, intercostal neuralgia, brachial neuritis, etc. A 5 per cent. w/v solution has been used for the injection of internal hæmorrhoids. A few minims may be injected directly into the pile or, alternatively, the whole area of the rectal mucous membrane may be treated by submucous injection, as much as 5 millilitres (75 minims) being used if required. The method should not be used for external sloughing, or strangulated hæmorrhoids, or when there is any local infection of the ano-rectal region. A solution of the same strength is used also in the treatment of anal fissure, 0·25 millilitre (4 minims) being injected superficially under the external half of the fissure. A fine, sharp needle must be used, and the injection made rapidly, since it is painful. Further injections may be necessary at intervals of two to three days. After treatment, undiluted ichthammol is applied to the surface. In pruritus of the anus, vulva, or scrotum, the affected parts may be infiltrated with a solution of quinine and urea hydrochloride, 0·25 to 0·5 per cent. w/v. The area should first be treated with an efficient antiseptic, and anaesthetised by injecting a 1 per cent. w/v solution of procaine hydrochloride. The injection of 4 to 8 millilitres (60 to 120 minims) of a 4 per cent. w/v solution is said to cause a reduction in the size of the enlarged thyroid gland in goitre. The sclerosing action of quinine and urea hydrochloride solution has been used in place of electro-cautery to treat vascular hypertrophy of the inferior turbinates. An injection of 2 to 3 millilitres (30 to 45 minims) of a 5 per cent. solution is made into the connective tissue, and a reduction in size takes place in eight to ten days.

Since solutions of quinine and urea hydrochloride do not readily penetrate mucous membrane, the compound is of limited value when applied locally, although strong solutions (10 to 20 per cent. w/v or stronger) have been applied locally in tonsillitis, tuberculosis of the larynx and other painful throat affections. Suppositories containing 0·2 to 0·3 gramme (3 to 5 grains) and ointment (20 per cent.) are used in the treatment of hæmorrhoids, fissure and other painful affections of the rectum. An ointment containing 1 per cent. of quinine and urea hydrochloride is used as an application to burns over large areas. Quinine and urea hydrochloride may also be employed for the therapeutic action of quinine. It is particularly suitable for intramuscular injection because of the freedom from pain and irritation. Strong solutions, however, are likely to cause local destruction of tissue, as do similar solutions of

other quinine salts. A solution of quinine and urea hydrochloride for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.03 to 1 gramme ($\frac{1}{2}$ to 15 grains), by injection.

QUININÆ GLYCEROPHOSPHAS

(Quinin. Glycerophosph.)

Quinine Glycerophosphate

Quinine glycerophosphate may be prepared by mixing a solution of calcium glycerophosphate in water with a solution of quinine hydrochloride in water, washing the resulting precipitate with a little cold water, draining and drying. It occurs in the form of fine, white, crystalline needles, or as a white, crystalline powder which is odourless and bitter, but not so intensely bitter as quinine sulphate. When anhydrous, it melts at 154° .

Soluble in water (about 1 in 200), boiling water (1 in 100), alcohol (1 in 40) and glycerin; easily soluble in boiling alcohol; insoluble in ether.

Standard.—Quinine glycerophosphate, determined by the method for Quininæ Acetylsalicylas, yields not less than 70 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 8.5 per cent. 1.4 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words “add 5 millilitres of dilute solution of ammonia. . . .”

Action and Uses.—Quinine glycerophosphate has the general properties of quinine salts, and may be **administered** in cachets or capsules.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

QUININÆ HYDRIODIDUM

(Quinin. Hydriod.)

Quinine Hydriodide

Quinine hydriodide may be prepared by precipitating a solution of quinine hydrochloride in hot water with a solution of potassium iodide in water. The precipitate is washed, and dried at a gentle heat. It

occurs in the form of pale yellow crystals or powder. It should be **stored** in the dark.

Slightly **soluble** in water; freely soluble in hot water, alcohol and ether.

Standard.—Quinine hydriodide, determined by the method for Quininæ Acetylsalicylas, yields not less than 71 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 1 per cent. Ash, not more than 0.5 per cent. 1.4 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine hydriodide has been given for tuberculosis and chronic rheumatism. It is best **administered** in cachets.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

QUININÆ DIHYDRIODIDUM.—Quinine dihydriodide (Quininæ Hydriodidum Acidum, quinine acid hydriodide), $C_{20}H_{24}O_2N_2 \cdot 2HI \cdot 5H_2O$, may be prepared by adding a solution of potassium iodide to a warm solution of quinine in dilute sulphuric acid, and crystallising. It occurs in the form of yellowish crystals or scales. On heating, the crystals become opaque at 30° and melt at 100° in their water of crystallisation, becoming completely anhydrous at 120° ; when the anhydrous salt is exposed to a damp atmosphere it takes up two molecules of water. It should be stored in the dark. Quinine dihydriodide is soluble in water (1 in 20). **Dose.**—0.06 to 0.3 gramme (1 to 5 grains).

QUININÆ HYDROBROMIDUM

(Quinin. Hydrobrom.)

Quinine Hydrobromide

Quinine hydrobromide may be prepared by the double decomposition of quinine sulphate and barium bromide, or by neutralising dilute hydrobromic acid with quinine. It occurs in the form of light, white, silky, acicular, odourless, efflorescent crystals, having a bitter taste. The aqueous solution is neutral or very slightly alkaline to litmus, and is non-fluorescent.

Soluble in water (about 1 in 55), boiling water (1 in 1), alcohol (1 in 0.7), chloroform (1 in 10) and glycerin.

Standard.—Quinine hydrobromide, determined by the method for Quininæ Acetylsalicylas, yields not less than 73 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 9 per cent. Ash, not more than 0.1 per cent. 1 gramme complies with the limit test for sulphates. 0.2 gramme in 12 millilitres of water produces no turbidity with dilute sulphuric acid (limit of barium). 0.05 gramme dissolved in 1 millilitre of sulphuric acid is not coloured more than light yellow

(limit of readily carbonisable substances). 1·3 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—The amount of hydrobromic acid present in this salt is insufficient to produce any bromide action. When given with a medicinal dose of hydrobromic acid, quinine is found to produce symptoms of quinism less often, and the sedative action of the mixture is useful in neuralgia and acute rheumatism. Quinine hydrobromide is used with dilute hydrobromic acid for the treatment of exophthalmic goitre. It may be **administered** in tablets, or in mixtures suspended with compound powder of tragacanth. In tablet making, quinine hydrobromide is more easily manipulated and produces a more satisfactory and soluble product than quinine sulphate.

Dose.—0·06 to 0·6 gramme (1 to 10 grains).

QUININÆ HYDROFLUORIDUM.—Quinine hydrofluoride, $C_{20}H_{24}O_2N_2 \cdot HF$, occurs as colourless crystals or as a white, amorphous powder. It is insoluble in water, but soluble in alcohol. Quinine hydrofluoride has been recommended for use in exophthalmic goitre. Dose.—0·06 to 0·12 gramme (1 to 2 grains).

QUININÆ HYDROCHLORIDUM

(Quinin. Hydrochlor.)

Quinine Hydrochloride

Quinine hydrochloride is the hydrochloride of the alkaloid quinine. It may be prepared by double decomposition of barium chloride and quinine sulphate. It occurs in the form of white, silky, glistening, acicular, odourless crystals, usually larger than those of quinine sulphate, efflorescent in warm air, and having a very bitter taste. It contains the equivalent of about 82 per cent. of anhydrous alkaloid. On exposure to light it gradually becomes yellowish in colour. The aqueous solution is levorotatory, and is neutral or faintly alkaline to litmus. The concentrated aqueous solution shows no fluorescence, but on considerable dilution a slight fluorescence is perceptible which increases on addition of sulphuric acid and disappears on the addition of hydrochloric acid.

Soluble in water (1 in 32), and alcohol (90 per cent.) (1 in 2).

Standard, B.P.—Quinine hydrochloride loses, on drying at 110° , not more than 10 per cent. of its weight. Ash, not more than 0·04 per cent. The 4 per cent. w/v aqueous solution is not fluorescent. It complies also with limit tests for readily carbonisable substances, inorganic salts and other alkaloids, barium, other cinchona alkaloids, and sulphate.

Action and Uses.—Quinine hydrochloride has the properties of quinine; it is more soluble and more readily absorbed than quinine sulphate, and is less irritating to the gastric mucosa. It is also employed in the form of pessaries, 0·2 to 0·3 gramme (3 to 5 grains) in each, with oil of theobroma, in leucorrhœa, and as a contraceptive. In conjunction with urethane as *Injectio Quininæ et Urethani*, it is used as a sclerosing agent in the treatment of varicose veins. It may be **administered** in cachets, tablets, and in solution in mixtures. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0·06 to 0·6 gramme (1 to 10 grains).

Preparations

Injectio Quininæ et Urethani, B.P.C.—(*Inj. Quinin. et Urethan.*)—Injection of Quinine and Urethane. A sterile aqueous solution containing quinine hydrochloride, about 13·5 per cent. w/v, and urethane, about 6·5 per cent. w/v. Dose.—5 millilitres (75 minims), by intravenous injection.

Tinctura Quininæ, B.P.C.—(*Tinct. Quinin.*)—Tincture of Quinine. Quinine hydrochloride, 1 in 50, in tincture of orange. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

Vinum Quininæ, B.P.C.—(*Vin. Quinin.*)—Quinine Wine. Quinine hydrochloride dissolved in orange wine, each fluid ounce contains 1 grain of quinine hydrochloride. Dose.—16 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This wine was included in the British Pharmacopœia, 1914.

QUININÆ HYPOPHOSPHIS

(*Quinin. Hypophosph.*)

Quinine Hypophosphite

Quinine hypophosphite may be obtained by dissolving quinine in hypophosphorous acid. It occurs as a colourless, crystalline salt, consisting of very small prisms, or as an amorphous powder. A solution in water acidified with dilute sulphuric acid produces a red precipitate with copper sulphate solution.

Soluble in water (1 in 24) and alcohol (1 in 40).

Standard.—Quinine hypophosphite, determined by the method for *Quininæ Acetylsalicylas*, yields not less than 74 per cent. of anhydrous quinine. Loss on drying at 100°, not more than 9 per cent. 1 gramme complies with the limit tests for chlorides. 1 gramme complies with the limit tests for sulphates. 0·2 gramme in 10 millilitres of water produces no turbidity with dilute sulphuric acid (limit of barium). 0·05 gramme dissolved in 1 millilitre of sulphuric acid is not coloured more than light yellow (limit of readily carbonisable substances). 1·3 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test

of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—The action of quinine hypophosphite is similar to that of other quinine salts. It is sometimes used in the preparation of hypophosphite syrups.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

QUININÆ LACTAS

(Quinin. Lact.)

Quinine Lactate

Quinine lactate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, \text{CH}_3\cdot\text{CHOH}\cdot\text{COOH}$, may be prepared by adding quinine to hot water and neutralising with lactic acid. It occurs in the form of anhydrous, colourless, prismatic needles resembling quinine sulphate in appearance, or as a white, crystalline or granular, amorphous powder.

Soluble in water (about 1 in 6) and boiling water (1 in less than 1); very soluble in alcohol; nearly insoluble in ether.

Standard.—Quinine lactate, determined by the method for Quininæ Acetylsalicylas, yields not less than 72 per cent. of anhydrous quinine. Loss on drying at 100° , not more than 3 per cent. Ash, not more than 0·1 per cent. 1·3 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine lactate has the general properties of other quinine salts, but it is not often used in medicine.

Dose.—0·06 to 0·3 gramme (1 to 5 grains).

QUININÆ PHOSPHAS

(Quinin. Phosph.)

Quinine Phosphate

Quinine phosphate may be prepared by suspending 10 parts of quinine in about 50 parts of hot water and adding sufficient phosphoric acid to give a solution just faintly acid to litmus. The solution is filtered while hot and allowed to crystallise. It occurs as white or slightly brownish, acicular crystals, similar to quinine sulphate but harder and denser.

Very slightly **soluble** in water (1 in 850) and chloroform (about 1 in 900); soluble in alcohol (90 per cent.) (1 in 110); insoluble in ether.

Standard.—Quinine phosphate, determined by the method for Quininæ Acetylsalicylas, yields not less than 74 per cent. and not more than 78 per cent. of anhydrous quinine. Loss on drying at 100°, not more than 10 per cent. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 1.3 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—The action of quinine phosphate is similar to that of other quinine salts. It is **administered** in tablets, and is sometimes used in the preparation of phosphate syrups.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

QUININÆ SALICYLAS

(Quinin. Salicyl.)

Quinine Salicylate

Quinine salicylate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, \text{C}_6\text{H}_4(\text{OH})\cdot\text{COOH}, \text{H}_2\text{O}$, may be prepared by the interaction of sodium salicylate and quinine sulphate in aqueous solution. It occurs in the form of white, silky, acicular crystals, or as a crystalline powder, assuming a pinkish colour on keeping. The aqueous solution is alkaline to litmus.

Very slightly **soluble** in water; soluble in alcohol (1 in 24) and chloroform (1 in 25).

Standard.—Quinine salicylate, determined by the method for Quininæ Acetylsalicylas, yields not less than 67 per cent. of anhydrous quinine. Loss on drying at 100°, not more than 4 per cent. Ash, not more than 0.1 per cent. 1.4 grammes, shaken in a separator with 50 millilitres of water containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine salicylate is sometimes employed at the onset of influenza, to abort the common cold, and as an analgesic in neuralgia and sciatica. It is **administered** in cachets, tablets, or pills, or suspended in water with compound powder of tragacanth. It is **incompatible** with mineral acids.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparation

Mistura Quininæ Salicylatis, B.P.C.—(Mist. Quinin. Salicyl.)—Mixture of Quinine Salicylate. Each fluid ounce contains 30 minims of ammoniated solution of quinine, 10 grains of potassium citrate and 10 grains of sodium salicylate, with glycerin and infusion of gentian. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

QUININÆ SULPHAS

(Quinin. Sulph.)

Quinine Sulphate

Quinine sulphate is the sulphate of the alkaloid quinine, and is obtained from the bark of various species of *Cinchona* as described under Quinina. It occurs as white, odourless, flexible, silky crystals, with a persistent, intensely bitter taste. It contains the equivalent of from about 73·5 to about 76·5 per cent. of anhydrous alkaloid. It is rapidly efflorescent in dry air or when heated to 50°, and loses $5\frac{1}{2}$ molecules of water of crystallisation, becoming lustreless. It becomes anhydrous when heated at 100°, and the anhydrous salt takes up moisture on exposure to air, forming the stable dihydrated compound. The aqueous solution is neutral or weakly alkaline to litmus. It may be distinguished from quinidine sulphate by the laevorotation of the aqueous solution. The alkaloid is precipitated from solutions of the sulphate by alkalis and alkali carbonates, but is slightly soluble in excess of solution of ammonia. It should be **stored** in well-closed containers and protected from light.

Soluble in water (1 in 800), boiling water (about 1 in 30), alcohol (90 per cent.) (1 in 65), boiling alcohol (90 per cent.) (1 in 6); almost insoluble in ether and chloroform; readily soluble in a mixture of 2 parts of chloroform and 1 part of dehydrated alcohol.

Standard, B.P.—Quinine sulphate loses, on drying at 100°, not less than 11 per cent. and not more than 16 per cent. of its weight. Ash, not more than 0·04 per cent. It complies also with limit tests for readily carbonisable substances, inorganic salts and other alkaloids, and other cinchona alkaloids.

Action and Uses.—Quinine sulphate has the general properties of quinine, and is the most commonly used salt of quinine, although for general purposes the hydrochloride or hydrobromide is sometimes preferred. Large doses are given in malarial and intermittent fevers, and smaller doses in continued fevers and neuralgia, and as a tonic to improve the appetite. For external use, 0·5 per cent. w/v solutions are employed as a spray or nasal douche in hay fever; for corneal ulcers, 0·2 per cent. w/v solutions are used. The salt is dissolved with a minimum of dilute sulphuric acid, or preferably the acid sulphate is employed.

Quinine sulphate may be **administered** mixed with milk, or in cachets or pills, or as a mixture, suspended with compound powder of tragacanth or dissolved with acid. 1 grain of quinine sulphate is rendered soluble in distilled water by 1 minim of dilute sulphuric acid or 2 minims of dilute phosphoric acid; the acid should in each case be diluted with from six to ten times its bulk of water before adding the quinine salt. It should not be dissolved by the addition of acid unless so ordered. Quinine sulphate is **incompatible** with alkalis and their carbonates, iodides, tannic acid and mercuric chloride. These substances precipitate the alkaloid or form insoluble salts which become adherent to the sides of the bottle; the addition of mucilage of acacia usually keeps the precipitated alkaloid in a diffusible condition. It is not suitable for the preparation of hypodermic injections; the dihydrobromide and dihydrochloride are used for this purpose.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

Preparations

Capsulæ Quininae Ammoniatæ, B.P.C.—(Caps. Quinin. Ammon.)—Capsules of Ammoniated Quinine. Each capsule contains quinine sulphate and ammonium bicarbonate and is approximately equivalent to 1 fluid drachm of solution of ammoniated quinine. Dose.—1 capsule.

Capsulæ Quininae Ammoniatæ et Cinnamomi, B.P.C.—(Caps. Quinin. Ammon. et Cinnam.)—Capsules of Ammoniated Quinine and Cinnamon. Each capsule contains quinine sulphate, ammonium bicarbonate and oil of cinnamon, and is approximately equivalent to 1 fluid drachm of solution of ammoniated quinine with $\frac{1}{2}$ minim of oil of cinnamon. Dose.—1 capsule.

Capsulæ Quininae et Cinnamomi, B.P.C.—(Caps. Quinin. et Cinnam.)—Capsules of Quinine and Cinnamon. Each capsule contains 1 grain of quinine sulphate and 1 minim of oil of cinnamon. Dose.—1 capsule.

Elixir Quininae Ammoniatum et Cinnamomi, B.P.C.—(Elix. Quinin. Ammon. et Cinnam.)—Ammoniated Elixir of Quinine and Cinnamon. Each fluid drachm contains about 1 grain of quinine sulphate with oil of cinnamon, ammonium carbonate, strong solution of ammonia, spirit of chloroform, syrup of orange, alcohol (90 per cent.), solution of cochineal and distilled water. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Quininae Ammoniatæ, B.P.—(Liq. Quinin. Ammon.)—Ammoniated Solution of Quinine. *Syn.*—Tinctura Quininae Ammoniatæ; Ammoniated Tincture of Quinine. It contains 2 per cent. w/v of quinine sulphate (limits, 1.9 to 2.1) and 1 per cent. w/v of NH_3 (limits, 0.9 to 1.05) in alcohol (60 per cent.). 4 millilitres contains 0.08 gramme, and 1 fluid drachm contains about 1 grain, of quinine sulphate. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Liquor Quininae et Strychninae, B.P.C.—(Liq. Quinin. et Strych.)—Solution of Quinine and Strychnine. It contains quinine sulphate equivalent to from 8.5 to 9.0 per cent. w/v of anhydrous quinine, and strychnine hydrochloride equivalent to from 0.186 to 0.206 per cent. w/v of strychnine, with hypophosphorous acid, glycerin and water. A syrup differing from Syrupus Ferri Phosphatis cum Quinina et Strychnina B.P. only in the presence of 0.75 per cent. v/v of hypophosphorous acid may be made by mixing 1 fluid ounce of this solution; 1 fluid ounce of solution of ferrous phosphate, $\frac{1}{2}$ fluid ounce of glycerin and 1 fluid ounce of distilled water with sufficient syrup to produce 8 fluid ounces.

Pilulæ Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Pil. Ferr. Phosph. c. Quinin. et Strych.)—Iron Phosphate Pills with Quinine and Strychnine. *Syn.*—Pilulæ Trium Phosphatum; Easton's Pills; Pilulæ Ferri et Quinina et Strychnina Phosphatum. Each pill contains $1\frac{1}{2}$ grains of saccharated iron phosphate, about $\frac{1}{2}$ grain of quinine sulphate and $\frac{1}{320}$ grain of strychnine hydrochloride and is approximately equivalent to $\frac{1}{2}$ fluid drachm of syrup of ferrous phosphate with quinine and strychnine. Dose.—1 or 2 pills.

Pilulæ Podophyllini et Quinina, B.P.C.—(Pil. Podoph. et Quinin.)—Podophyllin and Quinine Pills. *Syn.*—Poore's Pills. Each pill contains $\frac{1}{12}$ grain of resin of podophyllum, 1 grain of quinine sulphate, $\frac{1}{2}$ grain of extract of belladonna and 1 grain of aloes. Dose.—1 pill.

Pilulæ Quininae Sulphatis, B.P.C.—(Pil. Quinin. Sulph.)—Quinine Sulphate Pills. *Syn.*—Pilulæ Quininae; Quinine Pills. Each pill contains 2 grains of quinine sulphate. Dose.—1 to 4 pills.

The mass with which these pills are made contains approximately the same proportion of quinine sulphate as Pilula Quininae Sulphatis of the British Pharmacopœia, 1914, which was prepared with quinine sulphate, 82 grammes; tartaric acid, 3 grammes; tragacanth, 3 grammes; glycerin, 12 grammes.

Syrupus Ferri Phosphatis cum Quinina et Strychnina, B.P.—(Syr. Ferr. Phosph. c. Quinin. et Strych.)—Syrup of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Easton's Syrup. It contains iron equivalent to 1.8 per cent. w/v of anhydrous ferrous phosphate, $\text{Fe}_2(\text{PO}_4)_2$ (limits, 1.62 to 1.98), 1.09 per cent. w/v of anhydrous quinine (limits, 1.04 to 1.2), and 0.0246 per cent. w/v of strychnine (limits, 0.022 to 0.027), with syrup, glycerin and distilled water. 4 millilitres contains the equivalent of 0.072 gramme of anhydrous ferrous phosphate or about 0.034 gramme of iron, about 0.059 gramme of quinine sulphate, and about 0.0012 gramme of strychnine hydrochloride; 1 fluid drachm contains the equivalent of about 1 grain of anhydrous ferrous phosphate or about $\frac{1}{2}$ grain of iron, about $\frac{1}{2}$ grain of quinine sulphate and about $\frac{1}{64}$ grain of strychnine hydrochloride. The proportion of strychnine is approximately one half the proportion of strychnine contained in the corresponding preparation of the British Pharmacopœia, 1914. It should be stored in completely-filled, well-closed containers and protected from light. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellæ Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Tab. Ferr. Phosph. c. Quinin. et Strych.)—Tablets of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Tabellæ Trium Phosphatum; Easton's Tablets; Tabellæ Eastoni; Tabellæ Ferri et Quinina et Strychnina Phosphatum. Each tablet contains about $2\frac{1}{2}$ grains of saccharated iron phosphate, $\frac{1}{2}$ grain of quinine sulphate and about $\frac{1}{64}$ grain of strychnine hydrochloride, and is approximately equivalent to 1 fluid drachm of syrup of ferrous phosphate with quinine and strychnine. Dose.—1 tablet.

Tinctura Antiperiodica, B.P.C.—(Tinct. Antiperiod.)—Antiperiodic Tincture. *Syn.*—Warburg's Tincture. Aloes, about 1 in 40, quinine sulphate, 1 in 50, with rhubarb, angelica fruit, elecampane, saffron, fennel, chalk, gentian, cubeb, myrrh, agaric, opium, black pepper, cinnamon, ginger, zedoary and camphor. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

QUININÆ TANNAS

(Quinin. Tann.)

Quinine Tannate

Quinine tannate is the tannic acid compound of the alkaloid quinine. It may be prepared by the interaction of solutions of quinine sulphate

and tannic acid in the presence of ammonia. It occurs as a pale yellow or yellowish-white, amorphous powder, with an astringent taste which is not more than slightly bitter. When heated, it melts to a viscid, purplish mass. The saturated alcoholic solution gives a blue-black colouration on the addition of ferric chloride solution. It should be **stored** in well-closed containers and protected from light.

Slightly **soluble** in cold water; soluble in boiling water (about 1 in 30) and alcohol (90 per cent.) (about 1 in 3).

Standard, B.P.—Quinine tannate contains not less than 30 per cent. and not more than 35 per cent. of anhydrous quinine. Loss on drying at 100°, not more than 10 per cent. Ash, not more than 0.3 per cent. It complies also with limit tests for free quinine, other cinchona alkaloids, heavy metals, chloride and sulphate.

Action and Uses.—Quinine tannate is especially useful for children on account of its comparative freedom from bitterness. It is not less active than the more soluble quinine salts, and being absorbed only slowly is much more easily tolerated. It has been used especially in whooping cough and malaria. It is best **administered** in milk, or in tablets prepared with a chocolate basis.

Dose.—0.1 to 1 gramme (1½ to 15 grains).

QUININÆ VALERIANAS

(Quinin. Valer.)

Quinine Valerianate

Quinine valerianate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, \text{C}_4\text{H}_9\cdot\text{COOH}, \text{H}_2\text{O}$, may be prepared by the interaction of quinine and valerianic acid. It occurs in the form of colourless, lustrous, pearly crystals, or as a white, micro-crystalline powder, having a slight odour of valerianic acid and a bitter taste. Melting-point, about 90°, forming a colourless liquid. At 100° it loses its water of crystallisation and at the same time begins to lose valerianic acid.

Soluble in water (1 in 120), boiling water (1 in 40), alcohol (1 in 2) and ether (1 in 14).

Standard.—Quinine valerianate, determined by the method for Quininæ Acetylsalicylas, yields not less than 71 per cent. of anhydrous quinine. Ash, not more than 0.1 per cent. 1.4 grammes shaken in a separator with 50 millilitres of water, containing 5 millilitres of dilute sulphuric acid, complies with the test of the British Pharmacopœia for other cinchona alkaloids in Quininæ Hydrochloridum, commencing with the words "add 5 millilitres of dilute solution of ammonia. . . ."

Action and Uses.—Quinine valerianate is employed with the valerianates of iron and zinc in neurotic conditions and hysteria. It is **administered** in capsules or pills.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

Preparation

Pilulæ Ferri Valerianatis Compositæ, B.P.C.—(Pil. Ferr. Valer. Co.)—Compound Iron Valerianate Pills. *Syn.*—Pilulæ Trium Valerianatum. Each pill contains 1 grain each of the valerianates of iron, quinine and zinc. **Dose.**—1 or 2 pills.

RADIUM

(Radium)

Radium

$Ra = 226.0$

Radium is a disintegration product of uranium and is therefore found in all uranium minerals, such as pitchblende, which contains about 80 per cent. of uranium oxide, U_3O_8 , carnotite, potassium uranyl vanadate, $K(UO_2)VO_4 \cdot 1\frac{1}{2}H_2O$, etc. The ratio of radium to uranium in the minerals is constant, namely, about one to three million. Owing to the minute proportion present, the separation is a lengthy and expensive process. If the mineral contains no barium, a small quantity of a soluble barium salt is added to it, and the barium is then separated by the usual chemical methods. The whole of the radium associates itself with the barium, which it closely resembles. The radium is then separated from the barium by repeated fractional crystallisations of the chlorides or bromides, the radium halogen salts being less soluble in water and dilute mineral acids than the corresponding barium salts. Metallic radium has been prepared by electrolysing radium chloride with a mercury cathode and distilling the amalgam so formed in hydrogen under reduced pressure; after the last of the mercury had volatilised, radium remained as a pure white metal, melting at about 200° . Its chief compounds are the hydroxide, $Ra(OH)_2$, the halides, $RaCl_2$, $RaCl_2 \cdot 2H_2O$, $RaBr_2$, $RaBr_2 \cdot 2H_2O$, the nitrate, $Ra(NO_3)_2$, the sulphate, $RaSO_4$, and the carbonate, $RaCO_3$. Both in chemical properties and appearance, all these compounds closely resemble the analogous barium salts, the most stable being the sulphate.

The radioactive elements possess, in addition to the normal physical and chemical properties corresponding to their position in the periodic group, the property of radioactivity, that is, of emitting radiations, the atom spontaneously disintegrating until a stable atom (an atom which is not radioactive) is formed, the final result of disintegration being certain of the isotopes of lead. The process of disintegration cannot be controlled or altered by any methods that

have yet been tried. The radiations emitted are of three main types. The α -particle, which is a positively charged atom of helium, is the least penetrating of the three, and is absorbed by thin screens of paper or mica, or by about 3 inches of air. It is expelled with a velocity equal to about one-twentieth that of light. The β -particle is an electron or unit of negative electricity with an apparent mass of about $\frac{1}{1847}$ of the hydrogen atom. Its velocity of expulsion varies from one-third to almost equal to that of light, and it can penetrate a sheet of lead of about 3 millimetres thickness. The γ -ray carries no charge and, like X-rays, is a wave motion propagated with the velocity of light and is much more penetrating than either the α - or β -particles. These emanations ionise the air and discharge an electroscope, affect a photographic plate and cause fluorescence in substances such as barium platinocyanide, zinc sulphide, calcium sulphide, fluorspar, willemite, diamond and ruby. They promote certain chemical reactions, such as converting oxygen into ozone, and discolour paper and glass. They also affect the skin and produce painful, slowly healing sores.

Anhydrous radium bromide, RaBr_2 , is the salt usually found in commerce, and is sold on the basis of its radium content. A tube of radium or metallic uranium of known weight and activity is used as a standard. The international standard consists of 21.99 milligrams of pure radium chloride in a sealed glass tube kept at Paris; a duplicate is kept at Vienna, and the British standard of about 20 milligrams of pure radium chloride is kept at the National Physical Laboratory. The curie is an international standard for the amount of radium emanation in equilibrium with 1 gramme of radium. The usual strength of radium emanation water for internal use is 1 millicurie per litre. The Mache standard for radioactive water can be converted into the curie by taking 1 millicurie as equal to 2.7 million Mache units.

Action and Uses.—All the rays emitted by radium can produce effects on living tissue. These effects are similar in nature whichever type of radiation (alpha, beta or gamma) is used, and all degrees of cell damage may be produced up to the complete death of the cell. Although it is true that there is no tissue in the body that cannot be destroyed by exposure to any of the radiations of radium in sufficient dosage, the sensitivity of the different tissues and organs varies greatly. Among the more sensitive of these are the essential glandular cells of the testes and ovaries, the leucocytes, especially the lymphocytes and lymphatic tissues generally, the hæmopoietic tissues, the skin and mucous membrane, the secreting cells of the salivary glands, the conjunctiva and cartilage. Among the tissues more resistant to the radiations of radium are muscle, nerve tissue, the liver and the kidneys. On the skin an inflammatory reaction is caused which, when it stops short of vesication, is termed "erythema." The erythema is accompanied by epilation of hairy parts and depression in the activity of sweat and sebaceous glands. It subsides in a few days, and an almost normal skin remains, perhaps somewhat abnormally dry. Larger doses cause vesication, and still larger doses necrosis of all the layers. Ulcers so produced are extremely

difficult to heal and are often very painful. The effects described are those produced by large doses applied in a short period of time, such as are used in radium therapy. Repeated small doses, such as are sustained by those who have to handle radium in the course of their work, produce somewhat different effects, namely, dryness, hyperkeratosis and warts, fissures, and in some cases, eventually, epithelioma. In both types of exposure, but more commonly in the chronic type, telangiectases may follow. The effects upon mucous membranes are principally inflammatory. Cystitis, proctitis, vaginitis and other inflammations of the mucous membrane are commonly seen after therapeutic irradiation by radium, and perforation of hollow organs may follow. The action upon the sexual organs results in the destruction of the spermatogenic and oögenic cells, with consequent sterility. So far as is known, the internal secretory cells are not affected, and, in the male, sterility is not accompanied by impotence. Appreciable changes in the blood cells are only observed after large doses or repeated exposure to small doses as in the case of persons who habitually have to handle radium. The first effects are upon the leucocytes, the total number of which is reduced. While all forms of leucocytes suffer some reduction in their number, it is found that the lymphocytes suffer most, and these cells may form only 5 to 10 per cent. of the total count. The red cells and hæmoglobin may be moderately reduced, the colour index tending to fall. However, in chronic exposure to radium radiations there is probably a stage in which both red cells and hæmoglobin are increased slightly above normal, and the colour index may be above unity. Aplastic anæmia is said to be an end-result of repeated exposure to small doses of radium radiations.

Action on pathological tissues.—In general it may be said that the more active the reproductive activity of the cells of a tissue, the more sensitive to radiations will that tissue be. Thus, actively growing malignant tumours are more easily damaged than slowly growing ones, and innocent tumours are scarcely radio-sensitive at all. In all cases, the radio-sensitivity of pathological tissues has to be considered in relation to that of the normal tissues, since the dosage that can be applied in radium therapy must obviously be limited by the tolerance of the normal tissues. In most cases of malignant growths the margin is small, but in a few types of growths, e.g. lymphosarcoma and seminoma, the tumours are very radio-sensitive in relation to the normal tissues and can often be destroyed without causing appreciable damage to the latter. In most cases of carcinoma, however, the best results are obtained only when such doses are given as will cause inflammatory reaction in the healthy tissues, but it is important that dosage should be so regulated as not to cause irreparable damage. Among the carcinomata, the most sensitive are the squamous-celled variety, especially when occurring in the cervix, skin and throat. Columnar-celled carcinoma is the most resistant variety, especially that found in the rectum. Sarcomata are, on the whole, more sensitive than carcinomata, but the slowly growing varieties of fibro-sarcoma are often found to be quite

insensitive. Other conditions for which radium radiations are sometimes used are uterine fibroids, tuberculous glands and other tuberculous conditions, and nævi. In the treatment of fibroids, the radiations act by destroying the oögenic cells of the ovaries, with consequent arrest of hæmorrhage and secondary atrophy of the fibroids. It is possible that some direct effect upon the fibroids may also be produced. In tuberculous conditions, the effect is probably due to the production of a mild inflammation in the neighbourhood of the lesion, which promotes the resolution of the tuberculous process. In the case of nævi, the radiations act by causing obliteration of the blood vessels. The changes are seen principally in the endothelial lining of the vessel walls, but also as an increase of fibrous tissue in the vessel walls themselves.

Mode of Application.—Although radium has occasionally been administered in solution by the mouth and by injection, these methods have little therapeutic value and, except when the most minute dosage is employed, may be dangerous. Radium so administered has been detected after death in the tissues, especially the bone, by the characteristic radiations which continue to be emitted within the body. The usual mode of application of the radiations is directly to the lesion which it is desired to treat. Because of their extremely low penetrating power, the alpha rays are of little or no value for therapeutic purposes, and are completely absorbed in the wall of the radium container before they can reach the tissues of the patient. The thinnest beta rays have a limited penetrating power, so that their effects are manifest only in the immediate neighbourhood of the source of radiation. Their therapeutic value is therefore limited. They are occasionally used for the treatment of very superficial skin lesions, such as rodent ulcers, the radium being enclosed in a thin-walled plaque. The highly-penetrating gamma rays are, of course, also present, but their intensity is very small compared with that of the beta rays. The gamma rays have a very high penetrating power, and can be obtained almost free from alpha and beta rays by filtration through 0.6 millimetre of platinum, or an equivalent quantity of another metal. These rays are applied by three main methods, namely, transcutaneously, intracavally (in hollow organs) and interstitially. For transcutaneous or surface application, the radium is applied directly to the skin, with the intervention only of a layer of lint or rubber, for the treatment of superficial lesions, such as small rodent ulcers and nævi. For the treatment of deeper lesions, the radium is held at a suitable distance from the skin. The greater the distance the less will the rays diverge upon entering the tissues, and therefore the more deeply will they penetrate. For lesions which cover a wide area and do not extend too deeply, the radium may be applied upon a layer of columbia wax, which can be moulded to the surface. To lighten the weight of the apparatus, sheets of porous rubber are sometimes used in place of columbia wax. Several radium foci, usually from 2 to 5 milligrams or more, are uniformly distributed on the outer surface of the columbia

paste mould, and the whole apparatus is worn for several hours a day for several days. When malignant growths are being treated in this way, for example, malignant glands or small or recurrent carcinomata of the breast, treatment is persevered with until a definite erythema is observed. For the deepest lesions, large masses of radium may be applied at a distance of several centimetres from the surface—the so-called “bomb therapy”. For intracavitary irradiation, the radium, usually 50 or 100 milligrams, enclosed in a tube of platinum of not less than 0.6 millimetre thickness, is wrapped in rubber or gauze, introduced into the appropriate cavity, and left for a period varying from several hours to several days. For interstitial therapy, the radium is enclosed in sharp pointed, hollow needles. The radium content of these needles varies, but an average content is 0.5 milligram of radium to each centimetre of the needle. The needles are inserted into the affected region, either through the skin or at open operation, in such a way that a uniform network of needles is secured throughout and around the lesion. 10, 20, or even 30 needles may be employed in this way, with a total quantity of up to 100 or more milligrams of radium when an extensive lesion is treated.

Dose.—For internal use, daily doses of 0.005 milligram of radium bromide in solution have been given. Owing to the cumulative effect, it is doubtful if administration by this method is ever justifiable. For surface application, the dosage depends upon a great many technical factors, such as the distribution of radium in the applicator, the wall-thickness of the applicator and the distance of the applicator from the surface. The dosage is largely a matter for experimental determination with each applicator. The erythema dose is a valuable guide in this connection and, generally speaking, full erythema doses are required in the treatment of malignant conditions. A common method of expressing dosage is in “milligram-hours,” that is, the product of the number of milligrams of radium used and the number of hours for which it is applied. This statement of dosage is of little value unless it is accompanied by all the other details of the application. The same applies to the intracavitary and interstitial methods. As a rough guide, with a total quantity of 50 milligrams of radium, filtered by 0.6 millimetre of platinum and evenly distributed in needles throughout the cervix uteri and parametria, an average total dose would be from 5000 to 6000 milligram-hours.

RADON, or radium emanation, is used occasionally in the treatment of malignant disease. Its therapeutic indications and the radiations emitted are identical with those of radium salts, but in calculating dosage, allowance has to be made for the fact that the intensity of radiation is not constant, but is continuously decreasing, falling to half its value in 3.85 days. The emanation is filled into small gold or platinum containers; these are implanted in the tumour and allowed to remain in position for a calculated period of time. The containers, or “seeds”, have a thread attached, and frequently this is fixed in position with the aid of a solution of mastic in benzene.

RESORCINOL

(Resorcin.)

Resorcinol*Synonyms*—Resorcinum; Resorcin.

Resorcinol is *m*-dihydroxybenzene, $\text{C}_6\text{H}_4(\text{OH})_2$, and may be obtained by fusing sodium hydroxide with sodium *m*-benzenedisulphonate, cooling, dissolving in boiling water, adding hydrochloric acid and boiling until all sulphur dioxide is evolved. The solution is cooled and filtered, the filtrate extracted with ether, and the latter evaporated. The product thus obtained is purified by sublimation and recrystallised from water or benzene. Resorcinol occurs in white or nearly white, acicular crystals or as a crystalline powder. It has a slight but characteristic odour, and a taste which is unpleasant, sweetish and pungent at first and afterwards bitter.

On exposure to light and air, resorcinol becomes pinkish. In the presence of alkali the aqueous solution rapidly darkens and acquires a strong green fluorescence. It sublimes when heated above the melting-point. When a solution of resorcinol in sodium hydroxide solution is warmed with a trace of chloroform, an intense crimson colouration is produced, which changes to pale yellow when the mixture is rendered slightly acid with hydrochloric acid. On the addition of bromine water to the aqueous solution, a white precipitate of tribromoresorcinol is produced. When resorcinol is heated for a few minutes with an equal weight of phthalic anhydride, and the product dissolved in dilute sulphuric acid and poured into dilute ammonium hydroxide solution, a yellowish-green fluorescence is produced owing to the formation of fluorescein. It should be **stored** in well-closed containers and protected from light.

Soluble in water (4 in 3), alcohol (90 per cent.) (1 in 1), ether (1 in 1), glycerin (1 in 1) and olive oil (1 in 22); very slightly soluble in chloroform, carbon disulphide and benzene.

Standard, B.P.—Resorcinol has a melting point of 110° to 111° . Ash, not more than 0.05 per cent. The 5 per cent. w/v aqueous solution is neutral or only slightly acid to litmus and, when warmed, does not emit the odour of phenol. It complies also with a test for absence of catechol.

Action and Uses.—Resorcinol was formerly given internally as an antipyretic, but its use for this purpose has been abandoned on account of the readiness with which it forms methæmoglobin, and the consequent danger of collapse. It is more powerfully antiseptic than phenol, but is, perhaps, less poisonous and irritating. It is excreted in the urine in combination with sulphuric and glycuronic acids. Resorcinol is sometimes employed as a gargle (3 per cent.), and as an eye-lotion in conjunctivitis (1 per cent.). Solutions and ointments (2 to 10 per cent.) are used as antiseptic applications and for the local treatment

of laryngeal tuberculosis. It is a useful anti-pruritic, and ointments containing resorcinol with zinc oxide, salicylic acid, etc., are used in psoriasis, eczema, and other irritable skin affections. Resorcinol solutions, such as Spiritus Resorcinolis, are used as antiseptic applications to remove dandruff, but may slightly discolour fair hair unless all traces of soap or alkali are removed from the hair beforehand. Resorcinol is **incompatible** with alkalis and with Spiritus Aetheris Nitrosi.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

HYDROQUINONUM.—Hydroquinone, or quinol, is 1:4-dihydroxybenzene, $C_6H_4(OH)_2$, and may be prepared from phenol by oxidation with alkaline potassium persulphate or by the oxidation of aniline. It has a melting-point of about 170° , and a boiling-point of about 285° (730 mm. pressure). It is readily soluble in hot water, ether and alcohol. It is used as a photographic developer, often in conjunction with metol.

METOL.—Metol is methyl-*p*-aminophenol sulphate, $[C_6H_4(OH)(NH \cdot CH_3)]$, H_2SO_4 , and may be obtained by heating hydroquinone with aqueous methylamine under pressure and pouring the product into sulphuric acid. It has a melting-point of about 250° to 260° and is soluble in cold water (1 in 20) and boiling water (1 in 6). It is used in conjunction with hydroquinone as a photographic developer.

RESORCINOLIS MONOACETAS.—Resorcinol monoacetate may be prepared by the interaction of resorcinol and acetyl chloride. It occurs as a reddish-yellow, viscous liquid, soluble in acetone and in moderately dilute alcohol; it is used in solution in these solvents as a lotion in the treatment of dandruff, acne and seborrhœa.

Preparations

Pasta Resorcinolis, B.P.C.—(Past. Resorcin.)—Resorcinol Paste. *Syn.*—Pasta Resorcini; Resorcin Paste; Lassar's Stronger Resorcin Paste. Resorcinol, zinc oxide and starch, of each about 20 per cent., with liquid paraffin.

Pasta Resorcinolis Mitis, B.P.C.—(Past. Resorcin. Mit.)—Mild Resorcinol Paste. *Syn.*—Pasta Resorcini Mitis; Mild Resorcin Paste; Lassar's Mild Resorcin Paste. Resorcinol, about 10 per cent., zinc oxide and starch, of each about 25 per cent., with liquid paraffin.

Spiritus Resorcinolis, B.P.C.—(Sp. Resorcin.)—Spirit of Resorcinol. *Syn.*—Spiritus Resorcini; Spirit of Resorcin; Spiritus Capillaris; Lotio Resorcinolis Composita. Resorcinol and castor oil, of each 1 in 40, in Cologne spirit and alcohol (90 per cent.).

Unguentum Resorcinolis, B.P.C.—(Ung. Resorcin.)—Resorcinol Ointment. *Syn.*—Unguentum Resorcini; Resorcin Ointment. Resorcinol, 12.5 per cent., in glycerin, wool fat and white soft paraffin.

Unguentum Resorcinolis Compositum, B.P.C.—(Ung. Resorcin. Co.)—Compound Resorcinol Ointment. *Syn.*—Unguentum Resorcini Compositum; Compound Resorcin Ointment. Resorcinol, 4 per cent., and bismuth subnitrate, 8 per cent., with distilled water, starch, zinc oxide, birch tar oil, and potassium pyrosulphate, in wool fat, ceresin and yellow soft paraffin.

Unguentum Resorcinolis et Bismuthi Compositum, B.P.C.—(Ung. Resorcin. et Bism. Co.)—Compound Resorcinol and Bismuth Ointment. *Syn.*—Unguentum Resorcini et Bismuthi Compositum; Compound Resorcin and Bismuth Ointment. Resorcinol and bismuth subchloride, of each 8 per cent., with distilled water, zinc oxide, starch, birch tar oil, oil of cade and wool fat.

Unguentum Rusci Compositum, B.P.C.—(Ung. Rusc. Co.)—Compound Birch Tar Ointment. Birch tar oil, 8 per cent., with resorcinol, zinc oxide and starch, in hydraus wool fat and white soft paraffin.

Unguentum Sulphuris et Resorcinolis, B.P.C.—(Ung. Sulphur. et Resorcin.)
—Sulphur and Resorcinol Ointment. *Syn.*—Unguentum Sulphuris et Resorcinini; Sulphur and Resorcin Ointment. Sublimed sulphur, 4·5 per cent., and resorcinol, 3 per cent., in yellow soft paraffin.

RHAMNUS

(Rham.)

Buckthorn

Buckthorn is the fresh, ripe fruit of *Rhamnus catharticus* Linn. (Fam. Rhamnaceæ), a shrub indigenous to Great Britain.

The fruit is black, globular to ovoid, about 8 millimetres in diameter, with four loculi, each containing one seed; at the base are the remains of the calyx with a short pedicel attached, and at the apex is the scar of the stigma. The taste is at first sweetish, but afterwards bitter and acrid. Buckthorn **contains** dextrose, emodin, emodinanthranol, rhamnoxanthol, jesterin, rhamnocathartin and succinic acid, and the colouring matters, kæmpferolmethylether, rhamnetin, xanthorhamnin and quercetin.

Action and Uses.—The juice of buckthorn is employed in the preparation of Syrupus Rhamni which is used chiefly as a laxative in veterinary practice.

Preparation

Syrupus Rhamni, B.P.C.—(Syr. Rham.)—Syrup of Buckthorn. A solution of sucrose in the juice expressed from buckthorn fruit, containing also oil of pimento, alcohol (90 per cent.) and strong tincture of ginger. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

RHEUM

(Rheum)

Rhubarb

Synonyms—Rhei Rhizoma; Turkey Rhubarb.

Rhubarb consists of the rhizome of *Rheum palmatum* Linn. and possibly of other species of *Rheum* (Fam. Polygonaceæ) cultivated in China and Tibet, deprived of most of its bark, and dried. The rhizomes are dug up, the large, thick roots are cut off, the crown is removed and also more or less of the bark, after which the larger ones are cut transversely or halved longitudinally to facilitate drying, for which purpose the pieces are often strung on cords stretched from tree to tree, or placed on hurdles in a heated hut, or on heated stones.

Rhubarb occurs in heavy, compact pieces of various shapes, which are often perforated. Those from small, uncut rhizomes are cylindrical, conical, or barrel-shaped, and frequently from about 7 to 10 centimetres in length and 3 to 6 centimetres in thickness; they are known commercially as "rounds." Pieces from larger rhizomes,

split longitudinally, are plano-convex, and may be 8 to 15 centimetres in length and 4 to 10 centimetres wide; they are known as "flats." The pieces are sometimes covered with a bright yellow powder and, when this is removed, the surface shows numerous longitudinal, dark reddish-brown lines or spots embedded in a whitish matrix. The fracture is granular and uneven. The smoothed, transversely cut surface is pinkish-brown or greyish in colour and shows, near the periphery, a dark cambium line, which is sometimes removed with the whole of the phloem and external tissues during the peeling. Externally to the cambium may often be found the narrow remains of the secondary phloem, consisting of dark, reddish-brown medullary rays containing colouring matter, alternating with white lines of phloem parenchyma containing starch and calcium oxalate. Within the cambium is a narrow, radiate, normal secondary xylem, on the inner border of which occurs a ring of more or less united, star-like, vascular strands, consisting of dark red medullary rays radiating through a central, white phloem and peripheral xylem. Rhubarb gives a reddish-brown fluorescence when viewed in ultra-violet light. The drug has a characteristic, somewhat aromatic odour, and a bitter, slightly astringent taste.

The diagnostic **microscopical** characters are, in the parenchyma, the abundant starch grains, up to about 20 microns in diameter, either simple or compound, with up to about 5 components and showing a hilum usually in the form of a radiate split; the large cluster-crystals of calcium oxalate, about 20 to 200 microns in diameter and frequently more than 100 microns; an amorphous, yellow substance, insoluble in alcohol (90 per cent.) but soluble in water, and becoming reddish-pink on treatment with dilute solution of ammonia and deep red with solutions of caustic alkalis; the walls of the vessels and other elements of the xylem, which give no reactions for lignin; the absence of cork and of sclerenchymatous fibres and cells.

Rhubarb **contains** as its chief constituents certain anthraquinone derivatives. Among the substances which have been isolated from sun-dried Shensi rhubarb are cinnamic and gallic acids, tannin, rheinolic acid ($C_{17}H_{10}O_8$, melting-point, 295° to 297°), rhein, emodin, aloë-emodin, emodinmonomethylether, chrysophanic acid, and glycosides of the last five compounds. The chief purgative constituent of the drug is an amorphous, non-glycosidal resin which, on hydrolysis, yields cinnamic and gallic acids, rhein, emodin, aloë-emodin, emodin monomethylether, chrysophanic acid, and a compound, $C_{14}H_{12}O_3$, (melting-point, 256°), which is probably trihydroxydihydroanthracene. The drug also contains volatile oil, dextrose, lævulose, the phytosterol, verosterol, starch, calcium oxalate, and the following acids: palmitic, hexoic, stearic, oleic, linolic and linolenic.

Varieties.—The two important commercial varieties of Chinese rhubarb are known respectively as Shensi and Canton. Each may occur in "rounds" from the small rhizomes or "flats" from the larger, longitudinally split rhizomes. Shensi rhubarb has a bright yellow surface, is very compact, and shows distinct whitish reticulations which give rise to the characteristic "nutmeg" fracture; the best varieties have a bright pink tint on the freshly fractured surface.

Canton rhubarb has a more or less uniformly granular fracture and shows no distinct marbling; it is more fibrous and not so bright, the whitish reticulations being less distinct and the odour and taste less agreeable. Such commercial designations as "East Indian" or "Turkey" rhubarb refer to the route by which the drug formerly reached the European markets. Practically all Chinese rhubarb is now exported from Shanghai.

Substitutes.—"High-dried" rhubarb may resemble either the Shensi or Canton drug in the appearance of the fractured surface but the outer surface is duller and rougher, and the odour and taste are distinctly empyreumatic; the "rounds" are shrunken and frequently show the remains of the bud, and the surface bears dark patches; the "flats" are very hard and show signs of having been extensively trimmed. English rhubarb is obtained from *Rh. officinale* Baill. and *Rh. Rhaponticum* Linn. The rhizomes of *Rh. officinale* resemble the official drug but are softer and wrinkle strongly during the drying; the white reticulations are usually absent, and the star-spots are less numerous. The roots are also available and may be distinguished by the cylindrical shape and the radiate transverse section. The rhizome of *Rh. Rhaponticum* is also shrunken and usually pinkish in colour. It may be distinguished by the transverse section which shows a diffuse ring of isolated star-spots. It contains certain anthraquinone derivatives, and may be identified by the following test for the glycoside, rhaponticin, which it contains: 10 grammes of the powdered drug is percolated with alcohol (60 per cent.) and 25 millilitres of the percolate is evaporated at 80° to 7 grammes; the residue is shaken vigorously while warmed with 10 millilitres of ether, and the ethereal layer is set aside in a stoppered bottle; needle-shaped brownish crystals of rhaponticin separate within twenty-four hours. Rhapontic rhubarb is also imported from China and is known commercially as "Chinese rhapontic." It resembles the English drug but is usually darker, often hollow in the centre, and the radiate transverse section shows alternate paler and darker concentric rings. Rhapontic rhubarb gives a bright violet or lilac fluorescence when viewed in ultra-violet light.

Standard, B.P.—Rhubarb contains not more than 2 per cent. of foreign organic matter. Ash, not more than 15 per cent. Alcohol (45 per cent.)—soluble extractive not, less than 35 per cent.

Rhubarb, in powder (*Pulvis Rhei*: *Pulv. Rhei*), contains the constituents and possesses the diagnostic microscopical characters of Rheum, and complies with the limits for ash and alcohol-soluble extractive of the unground drug.

Action and Uses.—Rhubarb is employed as a stomachic in atonic dyspepsia and as a laxative. In large doses it is purgative by virtue of irritation of the large intestine. Purgation is followed by an astringent effect, owing to the tannin present. Preparations of rhubarb are suitable as occasional aperients, but should not be used in chronic constipation. A variable amount is absorbed, and imparts a yellowish-brown colour to the urine, which is changed to a purplish-red on the addition of alkali; symptoms of renal irritation are not, however, common. It is employed in diarrhœa due to irritating substances in the intestines, the after-astringent effect checking the diarrhœa. Rhubarb is **administered** as infusion or tincture, and in powder in cachets, powders, tablets, or mixtures, often with sodium bicarbonate and oil of peppermint. Small doses of the compound tincture or infusion may replace the powdered drug. *Pulvis Rhei Compositus* and *Syrupus Rhei* are employed as laxatives for delicate persons and children.

Dose.—0.2 to 1 gramme (3 to 15 grains).

Preparations

Extractum Rhei, B.P.C.—(Ext. Rhei)—Extract of Rhubarb. A dry extract. Dose.—0.12 to 0.5 gramme (2 to 8 grains).

This extract was included in the British Pharmacopœia, 1914.

Extractum Rhei Liquidum, B.P.C.—(Ext. Rhei Liq.)—Liquid Extract of Rhubarb. 1 in 1. Dose.—0.6 to 2 millilitres (10 to 30 minims).

Infusum Rhei Concentratum, B.P.C.—(Inf. Rhei Conc.)—Concentrated Infusion of Rhubarb. 1 in 2½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of rhubarb, and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Infusum Rhei Recens, B.P.C.—(Inf. Rhei Rec.)—Fresh Infusion of Rhubarb. 1 in 20. When infusion of rhubarb or Infusum Rhei is prescribed, fresh infusion not being specified, either Infusum Rhei Recens or Infusum Rhei Concentratum suitably diluted, may be dispensed. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Rhei.

Liquor Rhei Dulcis, B.P.C.—(Liq. Rhei Dulc.)—Sweet Solution of Rhubarb. *Syn.*—Elixir Rhei; Elixir of Rhubarb; Sweet Essence of Rhubarb. Liquid extract of rhubarb, 1 in 4, with oil of anise, syrup, glycerin, alcohol (90 per cent.) and distilled water. Dose.—4 to 12 millilitres (1 to 3 fluid drachms).

Mistura Rhei et Cascaræ, B.P.C.—(Mist. Rhei et Casc.)—Rhubarb and Cascara Mixture. Each fluid ounce contains 4 grains of rhubarb, 12 grains of sodium bicarbonate and 20 minims of liquid extract of cascara sagrada, with liquid extract of liquorice, syrup of ginger, oil of peppermint and chloroform water. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

Mistura Rhei et Sodii Bicarbonatis, B.P.C.—(Mist. Rhei et Sod. Bicarb.)—Rhubarb and Sodium Bicarbonate Mixture. *Syn.*—Mistura Rhei Composita; Mistura Rhei et Soda. Each fluid ounce contains 4 grains of rhubarb and 12 grains of sodium bicarbonate, with oil of peppermint, syrup of ginger and chloroform water. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

Pilulæ Hydrargyri cum Rheo, B.P.C.—(Pil. Hydrarg. c. Rheo)—Mercury Pills with Rhubarb. Each pill contains 2½ grains of pill of mercury and 2½ grains of compound pill of rhubarb. Dose.—1 pill.

Pilula Rhei Composita, B.P.—(Pil. Rhei Co.)—Compound Pill of Rhubarb. *Syn.*—Compound Rhubarb Pill. Rhubarb, about 25 per cent., and aloe, about 20 per cent., with myrrh, hard soap, oil of peppermint and syrup of liquid glucose. Dose.—0.25 to 0.5 gramme (4 to 8 grains).

Pulvis Rhei Compositus, B.P.—(Pulv. Rhei Co.)—Compound Powder of Rhubarb. *Syn.*—Gregory's Powder. Rhubarb, 25 per cent., with heavy magnesium carbonate, light magnesium carbonate and ginger. Dose.—0.6 to 4 grammes (10 to 60 grains).

Syrupus Rhei, B.P.C.—(Syr. Rhei)—Syrup of Rhubarb. Liquid extract of rhubarb, about 1 in 14, and oil of coriander, 1 in 2000, in syrup. Dose.—2 to 8 millilitres (½ to 2 fluid drachms).

This syrup, prepared directly from rhubarb by percolating 70 grammes in No. 20 powder with 270 millilitres of alcohol (90 per cent.) diluted with 810 millilitres of distilled water, dissolving 840 grammes of sucrose in the percolate previously evaporated to 475 grammes, adding 0.5 millilitre of oil of coriander dissolved in 10 millilitres of alcohol (90 per cent.) and adjusting the volume to 1000 millilitres with distilled water, was included in the British Pharmacopœia, 1914.

Tinctura Rhei Composita, B.P.—(Tinct. Rhei Co.)—Compound Tincture of Rhubarb. Rhubarb, 1 in 10, with cardamom, coriander and glycerin, prepared by percolation with alcohol (60 per cent.). Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellæ Rhei et Sodii Bicarbonatis, B.P.C.—(Tab. Rhei et Sod. Bicarb.)—Tablets of Rhubarb and Sodium Bicarbonate. *Syn.*—Rhubarb and Soda Tablets. Each tablet contains 3 grains of rhubarb, $1\frac{1}{2}$ grains of sodium bicarbonate and $\frac{1}{2}$ grain of ginger. Dose.— 1 or 2 tablets.

RHÆADOS PETALUM

(Rhæad. Pet.)

Red-Poppy Petal

Synonyms—Rhæados Petala; Red-Poppy Petals.

Red-poppy petal consists of the fresh or dried petals obtained from *Papaver Rhæas* Linn. (Fam. Papaveraceæ), a herb common in England and Europe.

The fresh petals are of a bright scarlet colour with a dark violet claw, broadly ovate in shape and about 6 centimetres in breadth, with an entire margin, within which the vein-endings anastomose to form a continuous row of small arches, leaving a band-like space, about 0.15 to 0.25 millimetre broad and quite destitute of veins. The odour is heavy and characteristic. When dried, the drug changes colour and loses about 90 per cent. of its weight. The dried petals are dull reddish-violet in colour and without odour, the taste being mucilaginous and slightly bitter. The application of acid restores the scarlet colour; alkalis turn it a greenish-blue. The ash is about 16 per cent.

The petals **contain** two anthocyanidin diglycosides, of which mecocyanin predominates. It contains also the crystalline, non-poisonous alkaloid, rhæadine; the presence of morphine has been alleged, but this has not been confirmed.

Substitutes.—*Papaver dubium* Linn. has petals about half the size of red-poppy petals, those of *P. Argemone* Linn. are still smaller; both plants can also be distinguished by the narrow and more oblong ovary and fruits.

Uses.—Red-poppy petal in the form of Syrupus Rhæados is used as a colouring agent for mixtures and gargles.

Preparation

Syrupus Rhæados, B.P.C.—(Syr. Rhæad.)—Syrup of Red-Poppy. A solution of sucrose in an aqueous infusion of dried red-poppy petal. Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup, prepared with five times the weight of fresh petal, was included in the British Pharmacopæia, 1914.

RHUS**(Rhus)****Rhus**

Synonyms—Rhus Glabra; Rhus Fructus; Sumach; Sumac Berries.

Rhus consists of the dried fruits of the smooth or Pennsylvanian sumach, *Rhus glabra* Linn. (Fam. Anacardiaceæ), a shrub 1 to 4 metres high, indigenous to Canada and the United States of America. The fruits develop on a large thyrse, from which they are easily detached.

The fruits are ovoid or reniform, slightly flattened, about 4 millimetres in diameter, but less in thickness. They are deep crimson externally, and covered with short, velvety hairs. The base usually has attached to it the remains of a five-pointed calyx and a short pedicel; the apex shows the faint scar from, or the remains of, the tripartite black style. The fruit contains a single greyish-yellow seed, about 2 millimetres in diameter. The drug is odourless, but has an acid, astringent taste.

Rhus **contains** malic acid, calcium acid malate, tannic and gallic acids, fixed oil and red colouring matter.

Standard.—Rhus contains not more than 5 per cent. of its stems and other foreign organic matter.

Action and Uses.—Rhus has astringent properties. It is reputed to have a diuretic action, but is seldom employed internally. It is used in the form of decoction (1 in 20) or liquid extract (1 in 1), mixed with glycerin and water, as a gargle, especially in conjunction with potassium chlorate.

Dose.—0.6 to 2 grammes (10 to 30 grains).

RICINI SEMEN**(Ricin. Sem.)****Castor Oil Seed**

Castor oil seed consists of the seeds obtained from *Ricinus communis* Linn. (Fam. Euphorbiaceæ), a native of India. The plant is cultivated in tropical and sub-tropical countries, and may be a tree, a shrub, or an annual herb, according to the climate.

The seeds are rounded, oblong and somewhat flattened, from 8 to 12 millimetres or more in length, with an arched, dorsal surface, and a nearly flat, ventral surface; the width is about two-thirds of the length, and the thickness about one-third. The seed coat, which is thin and brittle, is smooth and glossy, varying in colour from greyish-brown to grey, and mottled with reddish-brown or black spots and stripes. At one extremity of the seed there is a prominent and usually pale

coloured caruncle, from which the raphe runs along the ventral surface as a distinct line to the other extremity, where it terminates in a raised chalaza. The caruncle can be removed easily, disclosing the hilum beneath as a dark spot. A delicate, silvery-white membrane inside the seed coat surrounds a large, yellowish-white, oily endosperm, which encloses the embryo with two large, papery cotyledons. The seeds have scarcely any odour and only a very slight, acrid taste.

The diagnostic **microscopical** characters are the polygonal, pitted epidermal cells, some with, and others without, brown contents; the palisade layer of the seed coat, consisting of brown, pitted, sclerenchymatous cells; the large aleurone grains of the endosperm; the abundant fixed oil. The aleurone grains are round or ovoid, and measure up to about 20 microns in diameter.

Castor oil seed **contains** about 50 per cent. of fixed oil. The cake left after expression of the oil contains a crystalline principle, ricinine, the poisonous phytalbumose, ricin, and a very active lipase and other enzymes.

Action and Uses.—Castor oil seed is poisonous, and two or three seeds have been known to prove fatal. Even so small a dose of ricin as $\frac{1}{1000000}$ of the body weight may cause toxic symptoms when injected. The action of ricin is, however, much less powerful in the stomach than when injected hypodermically; in the latter case small doses soon produce immunity, anti-ricin being formed. The observation of this protective reaction laid the foundation of serum therapy. Lipase has been utilised commercially for splitting fats and oils.

ROSÆ FRUCTUS

(Ros. Fruct.)

Rose Fruit

Synonyms—Rosæ Caninæ Fructus; Dog Rose Fruits; Hips.

Rose fruit consists of the fresh, ripe fruits of *Rosa canina* Linn. (Fam. Rosaceæ) and other closely allied, indigenous species of *Rosa*.

The fruit is about 15 to 20 millimetres long and 10 to 12 millimetres wide, ovoid, smooth, shining and scarlet-red. It consists of the fleshy, concave, urn-shaped receptacle, bearing on its inner surface about 20 to 25 small, hairy achenes, each about 5 millimetres long and 2 millimetres broad. At its summit, the receptacle bears the scars left by the fall of the five sepals, and through the central opening the styles and stigmas protrude as a short, dense tuft of separate threads, each of which is attached to an achene. The taste is acid and agreeable.

Rose fruit **contains** malic and citric acids, sugar (about 30 per cent.), and a trace of tannin.

Substitute.—The fruit of the field rose, *R. arvensis* Huds., resembles that of *R. canina*, but is nearly globular and the styles of the achenes protrude in the form of a column.

Use.—Rose fruit is used in the preparation of confection, which is occasionally employed as a pill excipient.

Preparation

Confectio Rosæ Caninæ, B.P.C.—(Conf. Ros. Can.)—Confection of Rose Fruit.

Syn.—Confection of Hips. Rose fruit deprived of its achenes, beaten to a pulp and mixed with sucrose.

ROSÆ PETALUM

(Ros. Pet.)

Red-Rose Petal

Synonyms—Rosæ Gallicæ Petala; Red Rose Petals.

Red-rose petal consists of the petals obtained from the red or Provence rose, *Rosa gallica* Linn. (Fam. Rosaceæ), which is extensively cultivated throughout the world. The unexpanded petals are plucked as a whole from the receptacle, and the lighter coloured, basal portions cut off. They are used both fresh and dried, in the latter case being gently sifted to remove any stamens.

The petals generally occur in compact, conical masses, about 10 to 20 millimetres high and 9 to 13 millimetres wide. The individual petals, which are obovate to obcordate in shape, have a velvety upper surface of a deep purplish-red colour, paler towards the base. The odour is delicate and rose-like, and the taste is slightly astringent. The petals give a yellowish-red colour with acids, a green to brown colour with alkalis, and a deep blue with salts of iron.

The diagnostic **microscopical** characters are the straight-walled, papillose cells of the upper epidermis; the wavy-walled cells of the lower epidermis, with characteristic projections into their lumina; the slender, spiral vessels from the veins; the occasional cluster-crystals of calcium oxalate; the spherical pollen grains; the linear, unicellular hairs.

The drug **contains** the glycoside, cyanin (2 per cent.), which has been obtained as a dark brown, microcrystalline substance. It also contains a yellow, crystalline body, similar to, but not identical with, quercitin, together with gallic acid and possibly quercitannic acid.

Substitute.—Exhausted petals which have been recoloured have no pale region at the base.

Action and Uses.—Red-rose petal is mildly astringent; for this property, and for its colouring matter, it is used as Infusum Rosæ Acidum and as Syrupus Rosæ. Acid infusion of roses is a convenient vehicle for gargles containing alum or tannin; it should not be prescribed with borax or other alkaline salts. It is used also as a vehicle for quinine in mixture form. Red-rose petal is also employed in the preparation of Confectio Rosæ Gallicæ.

ROSÆ CENTIFOLIÆ PETALUM.—Pale-rose petal is obtained from the cabbage rose, *Rosa centifolia* Linn (Fam Rosaceæ), a shrub universally cultivated as a garden plant. The petals are large, thin, ovate and orbicular with a yellow claw, many of them being metamorphosed stamens. They are pale pink in colour and have a fragrant odour. Pale-rose petal contains a small quantity of volatile oil and a trace of a bitter principle.

Preparations

Confectio Rosæ Gallicæ, B.P.C.—(Conf Ros Gall)—Confection of Roses. Fresh red-rose petal and sucrose beaten together.

This confection was included in the British Pharmacopœia 1914.

Infusum Rosæ Acidum Concentratum, B.P.C.—(Inf Ros Acid Conc)—Concentrated Acid Infusion of Roses. About 1 in 5. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh acid infusion of roses, and differs also in containing a small proportion of alcohol. Dose—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Infusum Rosæ Acidum Recens, B.P.C.—(Inf Ros Acid Rec)—Fresh Acid Infusion of Roses. Red-rose petal dried, 1 in 40, with dilute sulphuric acid, 1 in 80. When acid infusion of roses or Infusum Rosæ Acidum is prescribed, fresh infusion not being specified, either Infusum Rosæ Acidum Recens or Infusum Rosæ Acidum Concentratum suitably diluted, may be dispensed. Dose—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Rosæ Acidum.

Syrupus Rosæ, B.P.C.—(Syr Ros)—Syrup of Rose. A solution of sucrose in an aqueous infusion of red rose petal, acidified with dilute sulphuric acid. Dose—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

This syrup, without the addition of dilute sulphuric acid, was included in the British Pharmacopœia, 1914.

RUBRUM SCARLATINUM

(Rub. Scarlat.)

Scarlet Red

Synonyms—Biebrich Scarlet R. Medicinal; Sudan IV.

Scarlet red is *o*-tolueneazo-*o*-tolueneazo- β -naphthol, $C_{24}H_{20}ON_4$, (Colour Index No. 258), and may be prepared by coupling diazotised *o*-aminoazotoluene with betanaphthol. It occurs as a dark, reddish-brown powder which melts between 165° and 185° . It dissolves in sulphuric acid, yielding a bluish-green solution, which gives a red precipitate on dilution.

Insoluble in water; soluble in alcohol, ether and fats.

Standard.—Scarlet red leaves not more than 10 per cent. of sulphated ash.

Action and Uses.—Scarlet red is used to promote the growth of epithelium in the treatment of wounds, burns and ulcers. It is generally applied as an ointment of from 1 to 8 per cent. strength, the basis of which may be lanolin or paraffin, and should be of such consistency

that the ointment adheres to the dressing when it is removed. This ointment is not applied to fresh wounds, and for granulating wounds only thin layers are used. An 8 per cent. ointment is irritant, and erosions and systemic effects have resulted from its use. For corneal abrasions and corneal ulcers a 1 per cent. ointment in soft paraffin is preferable. An alkaline alcoholic solution of scarlet red is used as a stain in microscopy for the identification of oil.

OIL SCARLET.—Oil scarlet (Colour Index No. 248), or Sudan III, is benzene-azobenzeneazo- β -naphthol, $C_{22}H_{16}ON_4$. It occurs as a reddish-brown powder which crystallises from acetic acid in brown plates with a green metallic lustre. It dissolves in sulphuric acid yielding a bluish-green solution which gives a red precipitate on dilution, and melts between 155° and 195° . It is insoluble in water but soluble in alcohol, ether and fats. Oil scarlet is said to have the same action as scarlet red and is sometimes used as a substitute for it.

TRYPAN BLUE.—Trypan blue (Colour Index No. 477), $C_{34}H_{24}O_{14}N_6S_4Na_4$, is the sodium salt of ditolyldisazobis-8-amino-1-naphthol-3 : 6-disulphonic acid. It occurs as a bluish-grey powder, soluble in water, forming a violet solution; insoluble in alcohol. The aqueous solution produces a violet precipitate with excess of hydrochloric acid, a violet solution and blue precipitate with sodium hydroxide solution and a greenish-blue solution with sulphuric acid or nitric acid, the solution turning blue and giving a violet precipitate on dilution. Trypan blue has been used in trypanosomiasis, and is said to have been successful in the treatment of canine and bovine piroplasmiasis and canine distemper. The dose for a dog weighing from 3 to 5 pounds is from 4 millilitres of a 0.5 per cent. w/v solution given intravenously. Solutions for injection may be sterilised by tyndallisation.

TRYPAN RED.—Trypan red (Colour Index No. 438), is the sodium salt of 3-sulphodiphenyldisazobis- β -naphthylamine-3 : 6-disulphonic acid. It occurs as a brown powder, soluble in water forming a red solution. The aqueous solution produces a blue precipitate with hydrochloric acid but is unaltered with acetic acid. Trypan red has been used in trypanosomiasis.

Preparation

Unguentum Rubri Scarlatine, B.P.C.—(Ung. Rub. Scarlat.)—Ointment of Scarlet Red. *Syn.*—Unguentum Rubrum. Scarlet red, 5 per cent., in simple ointment.

RUTA

(Rut.)

Rue

Synonyms—Rutæ Herba; Herbygrass.

Rue consists of the dried herb, *Ruta graveolens* Linn. (Fam. Rutaceæ), a perennial undershrub indigenous to Southern Europe, but commonly cultivated in Britain. It should be **stored** in closed containers.

The stem is cylindrical, branched and smooth. The leaves are bluish-green, alternate, bipinnate or tripinnate, with oblanceolate segments, wedge-shaped below, and punctate from the presence of oil glands in the mesophyll. The flowers are greenish-yellow, the parts being in fours, and in the terminal flowers in fives, the petals concave and

incurred at the tips. The odour is strong and characteristic, and the taste pungent and aromatic. The fruits are sub-spherical, brownish-green capsules, 5 to 7 millimetres in diameter, rough externally and four- or five-lobed at the apex.

Rue **contains** about 0.1 per cent. of volatile oil, which is contained in glands distributed over the entire plant. It also contains a yellow, crystalline body, rutin (rutic acid, sophorin, phytomelin, melin), $C_{27}H_{30}O_{16}$, melting-point, 188° to 190° , which yields, on hydrolysis with dilute acids, quercetin, dextrose and rhamnose.

Standard.—Rue contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—The properties of rue are virtually those of the volatile oil. The herb is sometimes employed in the form of infusion as an emmenagogue.

SABAL

(Sabal)

Sabal

Synonym—Saw Palmetto.

Sabal consists of the partly dried, ripe fruits of *Serenoa serrulata* Hook. f. (Fam. Palmæ), a fan palm which flourishes on the Atlantic coast of the United States of America from South Carolina to Florida.

The fruits are ovoid, about 20 millimetres long and 12 millimetres in diameter, externally brownish-black and smooth. The surface is slightly oily, even, or with large irregular depressions and ridges. The base shows either a short stalk or the small depressed scar left by its removal. A thin, tough epicarp, a soft sarcocarp, about 1 millimetre thick, and a thin, friable, smooth, brown endocarp enclose a hard, ovoid, reddish-brown seed, about 15 millimetres long and 6 millimetres in diameter. The odour is strongly aromatic and fruity, and the taste is sweetish, acid and oily.

Sabal **contains** about 1.5 per cent. of a brownish-yellow to dark red fixed oil.

Action and Uses.—Sabal is reputed to have a stimulant action upon the mucous membrane of the genito-urinary tract, this action being ascribed to the oil; it is therefore employed in sub-acute gonorrhœa and gleet, as well as in chronic and sub-acute cystitis. The drug is best **administered** in the form of liquid extract, which is sometimes combined with oil of sandal wood in a miscible form.

Dose.—1 gramme (15 grains).

Preparation

Extractum Sabal Liquidum, B.P.C.—(Ext. Sabal Liq.)—Liquid Extract of Sabal. *Syn.*—Liquid Extract of Saw Palmetto. 1 in 1. Dose.—0.6 to 1.5 millilitres (10 to 25 minims).

SABINA

(Sabin.)

Savin

Synonyms—Sabinæ Cacumina; Savin Tops; Sabinæ Herba.

Savin consists of the fresh or dried, young shoots of *Juniperus Sabina* Linn. (Fam. Pinaceæ), a small evergreen shrub indigenous to Southern Europe and cultivated in England. It is collected in the early summer.

The twigs are slender, sub-quadrangular, and densely covered with closely appressed, rhomboidal leaves, mostly in opposite and decussate pairs. The leaves, about 2 millimetres long, are usually adnate to the stem for a considerable portion of their length, and entirely appressed or sometimes strongly reflexed in the upper part. The apex is bluntly acute and, of the older twigs, subulate and spreading. At the centre of the outer (under) surface of each leaf is a solitary, large, oval depression, marking the position of a large oil gland; sub-spherical, drooping galbuli, about 5 to 8 millimetres in diameter, may be present in small numbers. The taste is acrid and bitter, and the odour strong, fœtid and characteristic.

The diagnostic **microscopical** characters are the stomata on the lateral parts only of the outer (under) surface of the leaves and near the central line on the inner (upper) surface, the guard-cells being lignified and the ostioles parallel to the axis of the leaf; the hypoderma, lignified and fibrous; on each side of the midrib, the lignified transfusion cells with bordered pits; the absence of stone cells; the minute prisms of calcium oxalate in the cuticle of the zone devoid of stomata.

The fresh drug **contains** from about 2 to 4 per cent. of volatile oil, together with tannin and resin.

Substitutes.—Young shoots of *Juniperus Phœnicea* Linn. are frequently substituted in France for savin. They are distinguished by the presence of lignified stone cells in the mesophyll and by differences in the characters of the volatile oil. *Juniperus virginiana* Linn. may be recognised by the transverse band of stomata below the level of the oil gland and by the small proportion (about 0·2 per cent.) of volatile oil which it contains.

Action and Uses.—The properties of savin are those of its volatile oil. Internally, it is a powerful gastro-intestinal irritant, large doses causing gastro-enteritis, hæmaturia and congestion of the pelvic organs. It is employed in small doses as an emmenagogue, acting reflexly by its irritation during excretion, but it must be given with caution. Its use as an abortifacient has often led to poisoning, with vomiting, severe diarrhœa, hæmaturia and, in severe cases, coma and death in three or four days. Externally, in the form of an ointment (1 in 10) prepared by digesting savin in a melted mixture of benzoined lard and yellow beeswax, it is sometimes employed as an irritant to promote discharge from ulcers and blisters. Savin is generally

administered as oil of savin given on sugar. A tincture (1 in 8), dose, 20 to 60 minims, was employed formerly.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

SACCHARINUM

(Saccharin.)

Saccharin

$C_7H_5O_3NS = 183\cdot1$

Synonym—Gluside.

Saccharin, or *o*-benzoic sulphinide, may be prepared by treating toluene with chlorosulphonic acid, thus forming a mixture of *o*- and *p*-toluenesulphochlorides, from which, on cooling, the para compound is eliminated by crystallisation. The ortho compound is then treated with ammonia whereby *o*-toluenesulphonamide, $C_6H_4(CH_3)SO_2NH_2$, is formed. This is oxidised with potassium permanganate and the solution is filtered from manganese hydroxides. On acidifying the filtrate, saccharin separates. It occurs as a light, white, microcrystalline powder. When 0·02 gramme is heated with 0·04 gramme of resorcinol and 0·5 millilitre of sulphuric acid until a green colour is produced, cooled, diluted with water and an excess of sodium hydroxide solution added, a fluorescent green solution is produced. When a small quantity in sodium hydroxide solution is evaporated to dryness, fused until no more ammonia is evolved, cooled, dissolved in water and neutralised with hydrochloric acid, on the addition of a few drops of ferric chloride solution to the filtered liquid a violet colour is produced. When a small quantity is boiled for ten minutes with dilute hydrochloric acid and evaporated to dryness, the residue on treatment with phenol and phosphorus pentoxide produces a red colour, and on dissolving this in water a yellow liquid is formed, which changes to bluish-red on the addition of alkali. Saccharin is about 550 times sweeter than sucrose.

Soluble in water (1 in 400), boiling water (1 in 28), alcohol (1 in 38) and glycerin (1 in 50); slightly soluble in ether and chloroform; very soluble in dilute solution of ammonia and in solution of sodium bicarbonate.

Standard.—Saccharin, determined by the method of the British Pharmacopœia for Saccharinum Solubile, contains not less than 97 per cent. of $C_7H_5O_3NS$; each millilitre of N/10 sulphuric acid is equivalent to 0·01831 gramme of $C_7H_5O_3NS$. Melting-point, not below 225°.

Action and Uses.—Saccharin is used as a sweetening agent and as a substitute for sugar in diabetes, obesity and generally where the use of sugar is undesirable. It is excreted unchanged in the urine. It is commonly employed in the form of soluble saccharin, which is more palatable, and has not the unpleasant after-taste of saccharin. For use

in dispensing Elixir Saccharini is suitable, the addition of 1 per cent. of this preparation to mixtures, etc., generally being sufficient.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Preparation

Elixir Saccharini, B.P.C.—(Elix. Saccharin.)—Elixir of Saccharin. *Syn.*—Elixir Glusidi; Elixir of Gluside. Saccharin, 1 in 20, with sodium bicarbonate, alcohol (90 per cent.) and distilled water. **Dose.**—0·3 to 1·2 millilitres (5 to 20 minims).

SACCHARINUM SOLUBILE

(Saccharin. Solub.)

Soluble Saccharin

Soluble saccharin is the sodium derivative of *o*-benzoicsulphinide, and may be obtained by neutralising saccharin with sodium hydroxide or sodium bicarbonate. It occurs as a white, crystalline powder which is odourless or has a faint, aromatic odour, and an intensely sweet taste, even in considerable dilution. It responds to the tests with resorcinol and sulphuric acid and with ferric chloride solution described under Saccharinum. On ignition, it yields a residue containing sodium sulphate.

Soluble in water (1 in 1·5 at 25°) and alcohol (95 per cent.) (1 in 50 at 25°).

Standard, B.P.—Soluble saccharin contains not less than 98 per cent. of $\text{C}_7\text{H}_4\text{O}_3\text{NSNa}\cdot 2\text{H}_2\text{O}$. Lead limit, 10 parts per million. The aqueous solution is slightly acid to litmus. The separated saccharin, when washed and dried, has a melting-point not lower than 226°. It complies also with a test for absence of benzoate and salicylate, and with a limit test for *p*-sulphaminobenzoic acid.

Action and Uses.—Soluble saccharin is more suitable than saccharin as a sweetening agent. It is used in the form of tablets, each containing the equivalent of 0·015 to 0·03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain) of saccharin.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

SAFROLUM

(Safrol.)

Safrole

Synonym—Safrol.

Safrole is the methylene ether of an allyl catechol. It is the chief

constituent of oil of sassafras, in which it exists to the extent of about 80 per cent., and it occurs also in other volatile oils. It is obtained almost entirely from essential oil of camphor by fractional distillation, collecting the fraction boiling at about 230° and purifying by repeated refrigeration and crystallisation. Safrole occurs at ordinary temperatures as a colourless or faintly yellow liquid, having a characteristic and pleasant sassafras-like odour, a sharp taste, and a neutral reaction. It is optically inactive. It crystallises in well-defined, colourless, monoclinic crystals, and boils at about 233°. Heated with alcoholic potassium hydroxide solution, *isosafole* is formed which boils at 246° to 248°. Both bodies dissolve in concentrated sulphuric acid, giving an intense red colour. Safrole resists reduction with sodium, but *isosafole* is readily reduced to dihydro-safrole, $C_{10}H_{12}O_2$. On oxidation with chromic acid mixture, safrole yields piperonal, or heliotropin, and piperonylic acid. Careful oxidation with potassium permanganate first converts it into a glycol, and on further oxidation into homopiperonylic acid.

Standard.—Safrole, determined by the method of the British Pharmacopœia for *Oleum Anisi*, has a melting-point not below 11° and a congealing-point not below 10°. Specific gravity, 1·104 to 1·107. Refractive index at 20°, 1·536 to 1·539. It is soluble in 3 volumes of alcohol (90 per cent.; specific gravity, 0·8334 to 0·8340) and in 10 volumes of alcohol (80 per cent.; specific gravity, 0·8634 to 0·8640).

Action and Uses.—Safrole has virtually the properties of oil of sassafras, and is used for similar purposes. It is rarely given internally, but it is sometimes employed, mixed with 2 or 3 parts of camphorated oil or liniment of methyl salicylate, as an anodyne liniment in chronic rheumatism. Safrole is also used as a parasiticide; it may be applied to the hair with a brush, leaving the skin untouched, thereby preventing undue absorption and irritation.

HELIOTROPINUM.—Heliotropin, or piperonal, $C_8H_8O_3$, may be obtained by the oxidation of *isosafole*, which is prepared from safrole by treatment with caustic alkali. It occurs as a white, crystalline solid, having a powerful, sweet odour and melting at 37°. It is used in perfumery.

SALICINUM

(Salicin.)

Salicin

Salicin, $C_6H_{11}O_5 \cdot O \cdot C_6H_4 \cdot CH_2OH$, is a crystalline glycoside obtained from the bark of various species of *Salix* and of *Populus*; a considerable quantity is obtained from the bark of *Salix fragilis* Linn., which is largely grown in Belgium, and contains about 3 per cent. of salicin. The bark of *S. purpurea* Linn. is particularly rich in salicin, containing

6 or 7 per cent., but the former bark is more commonly used. It may be extracted by heating a strong decoction of the bark with lead oxide, adding sulphuric acid and barium sulphide, filtering, evaporating to a syrupy consistence, and setting aside for the salicin to crystallise; it may be purified by recrystallisation. Salicin occurs as colourless crystals or as a white, crystalline powder, without odour but having a bitter taste. The aqueous solution is neutral to litmus. When salicin is heated in a test-tube until it begins to char, a violet colouration is produced on the addition of a small quantity of water and a drop of ferric chloride solution, due to the formation of salicyl alcohol (saligenin). When warmed with dilute acids, salicin is hydrolysed with formation of saligenin. It gives a blood-red colouration when moistened with sulphuric acid, the colour disappearing on adding water. When warmed with potassium dichromate and dilute sulphuric acid, the characteristic odour of salicylic aldehyde is evolved.

Soluble in water (1 in 28) and alcohol (90 per cent.) (1 in 80); insoluble in ether and chloroform.

Standard, B.P.—Salicin has a melting-point of 199° to 201° . Specific rotation in 3 per cent. w/v aqueous solution, -63° to -66° . Ash, not more than 0.05 per cent. It complies also with a test for absence of salicylic acid and of saligenin.

Action and Uses.—The action of salicin is virtually that of salicylic acid. It is less irritant to the mucous membranes than the salicylates. It is in part excreted unchanged in the urine and in part as salicyl alcohol, salicylic acid and salicyluric acid. Given in solution, it is bitter, increasing the flow of saliva and improving the appetite. It is used as a specific in acute rheumatism, for which purpose it is less depressing than salicylic acid and its action is more prolonged. It is also employed in influenza in doses up to 20 grains given at short intervals. It is best **administered** in solution in mixture form, but it may also be given in cachets or tablets.

Dose.—0.3 to 1 gramme (5 to 15 grains).

SALIX

(Salix)

Willow

Synonyms—Salicis Cortex; Willow Bark.

Willow consists of the bark of *Salix alba* Linn. and other species of *Salix*, notably *S. fragilis* Linn., *S. purpurea* Linn. and *S. pentandra* Linn. (Fam. Salicaceæ), trees indigenous to Britain and to Central and Southern Europe.

The bark occurs in thin, channelled pieces about 1 to 2 centimetres wide and from about 1 to 2 millimetres thick. The outer surface is glossy, smooth or slightly wrinkled longitudinally, or dull and rugged in older barks, brown, grey, or greenish in colour. The inner surface is

striated, fibrous, and yellow, pale red, or brown in colour. The fracture is short in the outer part and fibrous in the phloem, and the smoothed, transverse section exhibits under a lens numerous minute, tangentially arranged groups of bast fibres. The odour is slight, and the taste is astringent and slightly bitter.

The diagnostic **microscopical** characters are the 2 or 3 rows of cork cells, having strongly thickened and subersised, but not lignified, outer walls, which bulge outwards, the absence of stone cells from the phloem; the presence of prismatic crystals of calcium oxalate.

Willow **contains** tannin and salicin, the proportions of which are very variable.

Action and Uses.—Willow has been employed as a bitter and astringent.

SALIX NIGRA.—Black willow, or pussy-willow bark, is obtained from *Salix discolor* Muehl., a tree 15 to 25 feet high, common in North America. The bark occurs in long, thin, tough, fibrous strips, covered externally with a thin, brownish or greenish-brown, wrinkled cork, the inner surface is pale reddish-brown in colour. It has a bitter, astringent and somewhat aromatic taste. Black willow contains from 3.3 to 4.3 per cent of tannin, and about 1 per cent of salinigrin, a white, crystalline glycoside, soluble in water (1 in 52) and alcohol (1 in 218), melting-point, 195°, specific rotation, -87.3° , on hydrolysis it yields dextrose and *p*-hydroxyacetophenone; it may readily be distinguished from salicin by yielding a colourless solution with sulphuric acid. The bark of *Salix nigra* Marsh. is darker, thicker, and less bitter than that of *S. discolor*. Black willow has astringent and sedative properties, and has been prescribed to relieve ovarian pain. It is administered as liquid extract in mixtures with other sedatives.

Preparation

Extractum Salicis Nigræ Liquidum, B.P.C.—(Fxt Salic Nig Liq.)—Liquid Extract of Black Willow. 1 in 1. Dose—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

SALOL

(Salol)

Salol

Synonym—Phenyl Salicylate.

Salol, $C_6H_4(OH)COOC_6H_5$, is the phenyl ester of salicylic acid, and may be prepared by treating a mixture of sodium salicylate and sodium phenate, in molecular proportions, with phosphoryl chloride. The product is washed with water until practically free from chlorides and recrystallised. It occurs in the form of colourless, almost tasteless, translucent, needle-shaped crystals, or as a white, microcrystalline powder, having a very faint aromatic odour, recalling that of winter-green. An alcoholic solution forms an emulsion with water, due to suspension of the salt in a very finely divided state. The alcoholic solution is neutral to litmus paper, it yields a white precipitate with bromine solution and a violet colouration with ferric chloride solution.

When 0·2 gramme is boiled with 5 millilitres of sodium hydroxide solution, and the solution cooled and acidified with hydrochloric acid, an odour of phenol is developed and a white, crystalline precipitate of salicylic acid is produced.

Almost **insoluble** in water; soluble in alcohol (1 in 15); very soluble in boiling alcohol, ether (3 in 1), chloroform (3 in 1), liquid paraffin (1 in 10), almond oil (1 in 4), benzene, turpentine, balsam of copaiba, sandal wood oil and other fixed and volatile oils; very slightly soluble in glycerin.

Standard.—Salol melts between 42° and 43·5°. Ash, not more than 0·05 per cent. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. Shake 1 gramme with 20 millilitres of water, and filter; the filtrate produces no violet colouration on the addition of one drop of ferric chloride solution (limit of free phenol and free salicylic acid). 1 gramme suspended in 20 millilitres of water requires not more than 0·2 millilitre of N/10 sodium hydroxide for neutralisation, using phenol red as indicator.

Action and Uses.—Salol, when administered internally, is split up by the alkaline secretion of the small intestine into salicylic acid and phenol, both these bodies being excreted by the urine, which assumes a very dark colour. The effects of salol are due to the products of its decomposition. It is given mostly for its salicylic acid content, but the phenol produced is the cause of the poisoning that sometimes occurs, and this action should, therefore, not be overlooked. Salol is used principally as an intestinal antiseptic. Doubt has, however, been expressed as to whether it exerts much antiseptic action in the intestine, since, measured by the amount of indican in the urine, intestinal putrefaction does not appear to be diminished by its administration. Doses sufficiently large to be effective may produce toxic effects. It should not be employed when there is renal inflammation. Salol is employed as a substitute for the alkali salicylates in acute and chronic rheumatism.

Salol may be **administered** in cachets, or suspended in milk, or in mixtures with compound powder of tragacanth. It is given in tablets, sometimes with betanaphthol, but the tablets, unless lightly compressed, may pass through the alimentary tract undissolved. An emulsion may be prepared by dissolving salol in oil and emulsifying with acacia. *Liquor Salolis Compositus*, diluted with water, is used as a mouth-wash; *Pigmentum Salolis* is used for septic tonsils and inflammatory conditions of the throat. Salol is also used as a coating for pills, to render them insoluble in the stomach.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Preparations

Liquor Salolis Compositus, B.P.C.—(*Liq. Salol. Co.*)—Compound Solution of Salol. *Syn.*—Salol Mouth Wash. Salol, 2·5 per cent. w/v, with thymol, oil of peppermint, oil of anise, elixir of saccharin and alcohol (90 per cent.).

Pigmentum Salolis, B.P.C.—(*Pig. Salol.*)—Salol Paint. Salol, 1 in 300, in glycerin and alcohol (90 per cent.).

SALVIA

(Salv.)

Sage

Sage consists of the dried leaves of *Salvia officinalis* Linn. (Fam. Labiatæ), a perennial plant indigenous to Southern Europe, and largely cultivated.

The leaves are greyish-green, petiolate, elliptical or ovate-oblong, about 3 to 7 centimetres long, obtuse or subacute at the apex, rounded or subcordate at the base, thick, finely crenulate, very pubescent and conspicuously reticulately veined. The odour is aromatic and the taste bitter and somewhat astringent.

The diagnostic **microscopical** characters are the very numerous, long, narrow, uniseriate, 2 to 6-celled, covering trichomes with thick walls and sharply acute apices; the pieces of epidermis showing stomata of the caryophyllaceous type; the occasional, large, rosette-shaped, glandular trichomes with unicellular stalks and the small, glandular trichomes with a unicellular or bicellular head.

Sage **contains** volatile oil, 1 to 2.5 per cent., containing salvene, pinene, camphor, cineole, borneol, thujone, salvene esters and sesquiterpenes.

Standard.—Sage contains not more than 3 per cent. of foreign organic matter. Ash, not more than 8 per cent.

Sage, in powder (Pulvis *Salviæ* : Pulv. Salv.), contains the constituents and possesses the diagnostic microscopical characters of *Salvia*, and complies with the limit for ash of the unground drug.

Action and Uses.—*Salvia* has carminative properties and has been used in dyspepsia, but is mostly employed for culinary purposes.

CLARY SAGE or muscatel sage, from *Salvia Sclarea* Linn., indigenous to Northern Africa and Southern Europe and cultivated in the South of France, has broadly cordate-ovate leaves with pointed apices. The fresh, flowering tops yield about 0.1 per cent. of an essential oil, having an agreeable, aromatic, lavender-like odour, and containing linalol and esters.

SAMBUCUS

(Sambuc.)

Sambucus

Synonyms—Sambuci Flores; Elder Flowers.

Sambucus consists of the fresh or dried corollas and stamens from the flowers of *Sambucus nigra* Linn. (Fam. Caprifoliaceæ), a small tree or shrub indigenous to Europe, Western Asia and West Africa. The white or cream coloured flowers are borne in corymbose cymes from 15 to 20 centimetres in diameter, which are collected and thrown

into heaps; after a few hours the corollas become loosened and can then be removed by sifting.

The corollas are creamy-white, rotate, 5-lobed, gamopetalous, 1 to 3 millimetres in diameter, having 5 epipetalous stamens with short filaments and yellow anthers. A small proportion of pedicels and trilocular ovaries is commonly present. The odour of the fresh flowers is scarcely pleasant. The taste is slightly bitter and mucilaginous. The dried flowers have the form of brownish-yellow, shrivelled balls, which show the characters of the fresh flowers when soaked in water; the odour of the dried flowers is pleasant, and the taste is slightly bitter. *Sambucus* **contains** a trace of volatile oil, which is of buttery consistence at ordinary temperatures.

Substitute.—Elder flowers, preserved with 50 to 100 per cent. of common salt, are agreeably fragrant and are used for the preparation of the oil and the triple water of commerce.

Action and Uses.—*Sambucus* is used in the preparation of *Aqua Sambuci*. Elder-flower water is mildly astringent, and is used as a vehicle for lotions for the eyes and skin. The product gradually acquires an agreeably aromatic odour, and it is preferable not to use it until this change has taken place. Elder-flower ointment, prepared by heating fresh *sambucus* in melted lard, has been used as a basis for pomades and cosmetic ointments.

SAMBUCI FOLIUM.—*Sambucus* leaf consists of the fresh leaves of *Sambucus nigra* Linn. The leaves are opposite and decussate in arrangement; they are imparipinnate with 2 to 4, usually 2, pairs of leaflets, having very short petioles. The leaflets are from 3 to 8 centimetres long, ovate to lanceolate, glabrous, with an acuminate apex and a serrate margin; the upper surface is dark green and the under surface paler. *Sambucus* leaf contains an alkaloid, sambucine, a purgative resin, and the cyanogenetic glycoside, sambunigrin, which is isomeric with mandelonitrile glycoside or prunasin. Sambunigrin crystallises in white, felted needles, and is readily hydrolysed by emulsin, which is also present in the leaves, with production of hydrocyanic acid, benzaldehyde, and dextrose; by the action of small quantities of barium hydroxide it is readily converted into prulaurasin. *Sambucus* leaf yields about 0.16 per cent. of hydrocyanic acid. It also contains sucrose, invertin, a considerable quantity of potassium nitrate, and a crystalline substance, eldrin, which has also been found in other white flowering plants. The leaves have been used in the preparation of *Unguentum Sambuci Viride* and *Oleum Sambuci*. Green elder ointment was formerly prepared by digesting 1 part of the fresh leaves in 2 parts of a mixture of lard and suet; it is now commonly replaced by *Unguentum Sambuci*. Oil of elder leaves is prepared by digesting 1 part of bruised, fresh elder leaves in 3 parts of linseed oil.

Preparations

Aqua Sambuci, B.P.C.—(Aq. Sambuc.)—Elder-flower Water. Triple elder-flower water diluted, immediately before use, with twice its volume of distilled water.

Aqua Sambuci Triplex, B.P.C.—(Aq. Sambuc. Trip.)—Triple Elder-flower Water. The undiluted elder-flower water of commerce.

Unguentum Sambuci, B.P.C.—(Ung. Sambuc.)—Elder Ointment. Triple elder-flower water, 20 per cent., in simple ointment, coloured with chlorophyll.

SANDARACA

(Sandarac.)

Sandarac*Synonym*—Gum Juniper.

Sandarac is the resin obtained by incision from the stem of *Tetrclinis articulata* (Vahl) Masters (Fam. Cupressaceæ), a small tree growing on the mountains of North-Western Africa.

The resin is pale yellow, and occurs in brittle tears from 5 to 20 millimetres long and about 3 millimetres in diameter, usually of cylindrical or stalactitic form, and sometimes united into small masses of 2 or 4 tears each; the fracture is short, and the broken surface clear and vitreous. When chewed, the resin breaks up readily into a sandy powder which does not agglomerate into a plastic mass; the odour and taste are slightly terebinthinate. Specific gravity, about 1·07; melting-point, about 160°. Sandarac is completely **soluble** in alcohol and ether, partly soluble in chloroform, carbon disulphide and oil of turpentine. It leaves only traces of ash when incinerated.

Sandarac **contains** a resin with which is associated about 1 per cent. of volatile oil and traces of a bitter principle. The resin contains 85 per cent. of crystalline, inactive pimaric acid (sandaracopimaric acid), 2 to 3 per cent. of sandaracinic acid, and about 10 per cent. of callitrolic acid, together with a little sandaracoresene. Callitrolic acid is easily converted into the lactone, which is insoluble in alcohol. The acid number obtained by adding excess of alkali and titrating back varies from 90 to 154, the ester number being almost nil; these characters, however, appear to vary a little with the age of the resin.

Substitutes.—Australian sandarac, from *Callitris verrucosa* R.Br., is occasionally exported, but most of it is used in Australia. It closely resembles the genuine, but is often a little softer; from 5 to 22 per cent. dissolves in light petroleum. It contains the same constituents as the African sandarac but a larger proportion of inactive pimaric acid and pinene. Factitious sandarac made from colophony has an acid number of about 175, and is almost entirely soluble in light petroleum, which dissolves but little from sandarac.

Uses.—Sandarac is sometimes employed in alcoholic solution [2 parts of the resin and 1 part of alcohol (90 per cent.)] on cotton wool as a temporary filling for teeth. Its chief use in pharmacy is for the preparation of pill varnishes, but it is used largely as an ingredient of various varnishes.

SANGUINARIA

(Sanguin.)

Sanguinaria*Synonyms*—Bloodroot; Blood Root.

Sanguinaria is the dried rhizome of *Sanguinaria canadensis* Linn. (Fam. Papaveraceæ), a herb widely distributed throughout Canada and

the United States of America. It is collected in the autumn, and dried.

The rhizome occurs in dark grey or reddish-brown pieces from 2 to 10 centimetres long and 5 to 15 millimetres in thickness; it is sub-cylindrical, slightly curved or straight, and sometimes somewhat flattened. The surface shows incompletely encircling leaf-scars; the apex is blunt and conical, showing traces of a bud or of the aerial stem. The roots are few, up to 1 millimetre thick, brittle and wiry, and the root-scars are raised. The branches are short and knob-like, arising at right angles to the rhizome. The fracture is short, and the fractured surface sometimes starchy and whitish, with numerous, minute, deep red, secretion cells, or hard and resinous, and of a uniform dark red or brown colour. The odour is slight and the taste bitter and acrid.

Sanguinaria contains the alkaloids, sanguinarine, chelerythrine, protopine and α - and β -homochelidonine, a red resin and abundance of starch.

Action and Uses.—*Sanguinaria* is occasionally employed as an expectorant in chronic bronchitis, and is **administered** as tincture (1 in 10) in doses of 1 millilitre (15 minims).

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

SANGUIS DRACONIS

(Sang. Drac.)

Dragon's Blood

Synonym—Sumatra Dragon's Blood.

Dragon's blood is a resinous secretion found on the fruits of *Dæmonorops propinquus* Becc., *D. Draco* Blume and probably other species of *Dæmonorops* (Fam. Palmæ), rattan palms indigenous to Sumatra and Borneo. The fruits, about the size of a cherry, are enveloped in closely imbricated, hard, yellow scales, which become encrusted with a red resin. The resin is removed by shaking the fruits and sifting, and is then softened by warming and made into elongated, flattened, or rounded masses, the latter frequently bearing the impress of coarse matting in which they have been packed, whilst the former are generally wrapped in a leaf. It is stated that a certain amount of admixture with the milky juice of *Garcinia parviflora* Benth. (Fam. Guttiferæ) occurs.

Dragon's blood occurs in pieces of varying size and shape, frequently in large, rounded lumps weighing up to several pounds, or in rounded, flattened cakes, or occasionally in sticks. The higher grades are of a dull red colour, covered with a dull crimson powder due to friction, and are brittle and friable. The fracture is vitreous, exposing a nearly black surface; thin fragments are translucent, and of a garnet-red colour by transmitted light. When crushed, the resin yields a bright crimson powder. Inferior qualities are duller, tougher and have less powder

on the surface; on crushing, they give a duller crimson or brick-red powder, and they usually contain numerous fragments of fruit scales, etc. The resin is odourless, almost tasteless, gritty when chewed, and melts at about 120°, evolving an odour of benzoic acid. It is entirely soluble in alcohol, but the crude drug may yield from 40 to 50 per cent. of insoluble residue.

The soluble portion of dragon's blood **consists** of about 56 per cent. of a red resin (dracoresinotannol combined with benzoic and benzoyl-acetic acids), 13 per cent. of a bright yellow, amorphous resene (dracoresene), and 2.5 per cent. of a white, amorphous body (dracoalban). The latter may be detected by boiling 10 grammes of the powdered resin in 50 millilitres of ether, concentrating to 30 millilitres, and pouring into 50 millilitres of dehydrated alcohol; on allowing the mixture to stand for an hour, a white, flocculent precipitate of dracoalban is obtained.

Substitutes.—Socotra dragon's blood, or "Zanzibar drop," from *Dracæna cinnabari* Balf. f. (Fam. Liliacæ), indigenous to Somaliland, occurs in tears, contains no fruit scales and does not emit an odour of benzoic acid when warmed. The dried juice from the bark of *Pterocarpus Draco* Linn. (Fam. Leguminosæ) is known as American or West Indian dragon's blood, or as West Indian kino.

Standard.—Dragon's blood yields not more than 9 per cent. of ash.

Uses.—Dragon's blood is sometimes used for colouring plasters, but it is much more largely used for colouring lacquers and varnishes. It is also used in zinc line engraving to protect from the action of the acid those parts of the metal not to be etched.

SANTONICA

(Santonin.)

Santonica

Synonyms—Semen Contra; Semen Cinæ; Wormseed.

Santonica consists of the dried, unexpanded capitula of *Artemisia cina* Berg (Fam. Compositæ), a small undershrub which grows plentifully in Turkestan.

The capitulum is from 2 to 4 millimetres long and 1 to 2 millimetres wide, light brown, ovoid and somewhat angular, shining and nearly glabrous. The ovate involucrel bracts vary in number from about 14 to 20 (most frequently 16); they are keeled, and bear shining, external glands; their midribs branch freely, and the veinlets are contorted and frequently anastomose; they have no apical, marginal hairs and few cottony hairs. The 3 to 5 florets are minute, tubular and hermaphrodite; the apices of their corolla lobes are never more than slightly papillose and bear no trichomes. The odour is agreeable and aromatic, and the taste is bitter, aromatic and camphoraceous. Portions

of the foliage leaves are always present and afford good diagnostic characters; they have linear-lanceolate pinnæ with a rounded apex and an apiculus; each pinna has lateral veins connecting the midrib with two parallel, sub-marginal veins; numerous sessile glands are present, but long, protective hairs are absent.

Santonica contains santonin (2 to 3·5 per cent.), which rapidly diminishes in quantity after the flowerheads have expanded. The drug also contains artemisin, $C_{15}H_{18}O_4$ (melting-point, 200°), which yields a carmine-red solution when boiled with solution of sodium hydroxide, a bitter resin, betaine, choline and a hydrocarbon, $C_{32}H_{66}$. The odour of santonica is due to a yellow volatile oil (2 to 3 per cent., specific gravity, 0·915 to 0·940). The ash is about 10 per cent.

Substitutes.—A variety of wormseed ascribed to *Artemisia brevifolia* Wall. is collected in India and contains a smaller proportion of santonin than santonica. A spurious variety containing no santonin is obtained from the Persian gulf.

Standard.—Santonica contains not less than 2 per cent. of santonin.

Santonica, in powder (Pulvis Santonicæ : Pulv. Santonic.), contains the constituents of Santonica, and complies with the standard for the unground drug.

Assay.—Take 13 grammes, in coarse powder, and shake occasionally for one hour with 130 grammes of chloroform. Filter through cotton wool, and transfer 102·5 grammes of the solution, representing 10 grammes of the drug, to a 200 millilitre tared flask; distil off the chloroform until the residue weighs between 7 and 8 grammes, add 100 grammes of 1·20 per cent. w/v barium hydroxide solution, and heat the flask on a water-bath until all the chloroform is driven off. Filter the liquid, wash the filter with a little boiling water, acidify the filtrate with 5 grammes of 25 per cent. hydrochloric acid, heat on the water-bath for a few minutes and then, when lukewarm, transfer to a separator. Rinse the flask with 20 millilitres of chloroform, add the latter to the separator and shake briskly for two minutes. Separate the chloroform into a 100 millilitre flask and extract the aqueous liquid with two successive portions of 20 millilitres of chloroform. Evaporate the chloroform, take up the residue, with the aid of heat, in 7·5 grammes of dehydrated alcohol, and then mix with 42·5 grammes of hot water. Filter the milky solution immediately into a tared 100 millilitre flask, rinse the filter and flask with two portions, each of 10 millilitres, of a mixture of 3 grammes of dehydrated alcohol and 17 grammes of hot water, and allow the liquid to stand for twenty-four hours. Collect the separated santonin on a tared filter, wash the flask and filter with two portions of 10 millilitres each of a mixture of 3 grammes of dehydrated alcohol and 17 grammes of water, and dry the flask and filter to constant weight. To the weight of santonin obtained add 0·04 gramme, in order to correct for the santonin remaining dissolved in the solution.

Action and Use.—Santonica is used chiefly as the source of santonin. It is sometimes administered in the form of decoction or infusion for the expulsion of round-worms and thread-worms.

SPIGELIA.—*Spigelia*, Indian pink, or pink root, consists of the dried rhizome and rootlets, or the dried entire plant, of the Carolina pink, *Spigelia marilandica* Linn. (Fam. Loganiaceæ), a native of the Southern United States. The plant is a herbaceous perennial, from 30 to 50 centimetres high, having a smooth, simple stem, rounded below, quadrangular above and bearing a few opposite, sessile, ovate-lanceolate leaves about 7·5 centimetres long. The stem sometimes terminates in a spike of brilliant red flowers. The rhizome is 5 centimetres or more in length and 2 to 3 millimetres in diameter, dark brown externally, tortuous and knotty, and bears numerous slender, wiry rootlets and cup-shaped stem-scars. Internally, the rhizome has a whitish wood and a dark-coloured or decayed pith. The drug has a somewhat aromatic odour and a sweetish but bitter and pungent taste. The chief constituents are the poisonous alkaloid, spigeline, and an acrid, bitter substance soluble in water and alcohol. *Spigelia* is used as an anthelmintic for round-worms, being administered in powder or as an infusion mixed with purgatives such as senna. Its administration should be followed by a saline purge. Dose.—2 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

SANTONINUM

(Santonin.)

Santonin

Santonin is a crystalline lactone obtained from *santonica* and from other species of *Artemisia*. It may be extracted by mixing *santonica* with milk of lime and decomposing by means of sulphuric acid; santonin crystallises out on cooling the acid liquid, and is washed with ammoniacal water and purified by recrystallisation. It occurs as colourless crystals, without odour and almost tasteless at first but afterwards slightly bitter. Exposure to daylight causes it to assume a yellow colour due to formation of chromosantonin. Alkaline solutions convert santonin into santonates, from which santoninic acid may be obtained by shaking with hydrochloric acid and ether. When a trace of santonin is warmed with alcoholic potassium hydroxide solution, a violet-red colour is obtained. When warmed on a water-bath with 5 millilitres of a mixture of equal volumes of sulphuric acid and water to which a trace of ferric chloride has been added, a yellow colouration is produced which changes slowly to red and then violet. Warmed with solution of ethyl nitrite and a few drops of potassium hydroxide solution, a fine rose-red colour is produced. It should be **stored** protected from light.

Soluble in alcohol (90 per cent.) (1 in 44), boiling alcohol (90 per cent.) (1 in 3), chloroform (1 in 2·5) and ether (1 in 140); almost insoluble in water.

Standard, B.P.—Santonin has a melting-point of 171° to 174°. Ash, not more than 0·1 per cent. The 2 per cent. w/v alcoholic solution is clear and neutral to litmus. It complies also with a limit test for readily carbonisable substances.

Action and Uses.—Santonin is used as a vermifuge for ascarides (round-worms). Its action appears not to be that of a direct poison

to the parasites, since they are expelled alive. It causes the worms to migrate to the lower gut, whence they are removed by a suitable purge, either calomel given simultaneously or castor oil given twelve hours after the santonin. It is also used to expel oxyuris (thread-worms), but has no action on tænia (tape-worms). Santonin is liable to be absorbed, giving rise to specific effects on the sense organs, especially the colour sense and central nervous system. Appreciation of colour is disturbed, and illuminated objects appear to have a yellowish tinge, which is sometimes preceded by a faint blue colour. Santonin may also cause headache, nausea and vomiting, or, in large doses, epileptiform convulsions. The absorbed santonin renders the urine an intense yellow colour, if acid, or purplish, if alkaline. Santonin may be **administered** in powders or tablets, one dose each night for three nights, followed each morning by a dose of castor oil. It may be suspended in a mixture with compound powder of tragacanth, or given as Trochisci Santonini. It is often given in tablets with compound powder of scammony or calomel.

Dose.— 0·06 to 0·2 gramme (1 to 3 grains).

Preparations

Tabellæ Santonini et Hydrargyri Subchloridi, B.P.C.—(Tab. Santonin. et Hydrarg. Subchlor.)—Tablets of Santonin and Mercurous Chloride. *Syn.*—Compound Santonin Tablets; Santonin and Calomel Tablets; Tabellæ Santonini Compositæ. Each tablet contains 1 grain of santonin and 1 grain of calomel. Dose.— 1 or 2 tablets.

Tabellæ Santonini et Scammonie Compositæ, B.P.C.—(Tab. Santonin. et Scammon. Co.)—Compound Tablets of Santonin and Scammony. Each tablet contains $1\frac{1}{2}$ grains of santonin, 2 grains of compound powder of scammony and $\frac{1}{2}$ grain of calomel. Dose.— 1 tablet.

Trochisci Santonini, B.P.C.—(Troch. Santonin.)—Santonin Lozenges. Each lozenge contains 1 grain of santonin.

This lozenge, containing 0·06 gramme of santonin, was included in the British Pharmacopœia, 1914.

SAPO ANIMALIS

(Sap. Animal.)

Curd Soap

Curd soap is a sodium soap prepared from animal fats, and consists chiefly of sodium stearate. It may be prepared by heating the purified animal fat, consisting chiefly of stearin, with sodium hydroxide and water; on adding common salt to the liquid, the soap separates as a curd. Curd soap occurs as a yellowish-white or greyish-white solid, almost free from odour. It becomes plastic when heated, and horny and readily pulverisable when dry.

Soluble in hot water; sparingly soluble in cold water; almost completely soluble in alcohol (90 per cent.).

Standard, B.P.—Curd soap loses, on drying at 110° , not less than 20 per cent. and not more than 30 per cent. of its weight. Curd soap, in powder, loses, on drying at 110° , not more than 5 per cent. of its weight. Solidifying-point of the fatty acids, not less than 42° . It complies also with limit tests for alkali hydroxide and free fatty acid, alkali carbonate, and free fat.

Uses.—Curd soap is a useful pill excipient for resinous substances and volatile oils. A solution containing 4 ounces of curd soap and 6 fluid ounces of glycerin in sufficient water to produce 30 fluid ounces is used to smear over electrodes to ensure good electrical contact in electro-therapeutic practice; it is known as "contact" soap.

Preparation

Emplastrum Saponis Fuscum, B.P.C.—(Emp. Sap. Fusc.)—Brown Plaster of Soap. *Syn.*—Emplastrum Cerati Saponis. It is prepared with curd soap, yellow beeswax, olive oil, lead monoxide and vinegar.

Linimentum Saponis Camphoratum, B.P.C.—(Lin. Sap. Camph.)—Camphorated Soap Liniment. *Syn.*—Solid Opodeldoc. A solid preparation containing curd soap, camphor, oils of thyme and rosemary, dilute solution of ammonia and alcohol (90 per cent.).

SAPO DURUS

(Sap. Dur.)

Hard Soap

Hard soap is a sodium soap prepared from olive oil, and consists chiefly of sodium oleate. It may be prepared by heating olive oil with sodium hydroxide and water; on adding common salt to the liquid, the soap separates as a curd. Hard soap occurs as a yellowish-white, greyish-white, or greenish-white solid, almost free from odour. It becomes plastic when heated, and horny and readily pulverisable when dry.

Soluble in water (1 in 20), boiling water (1 in 1.5); almost completely soluble in alcohol (90 per cent.), and entirely soluble in boiling alcohol (90 per cent.) (1 in 2).

Standard, B.P.—Hard soap loses, on drying at 110° , not less than 20 per cent. and not more than 30 per cent. of its weight. Hard soap, in powder, loses, on drying at 110° , not more than 5 per cent. of its weight. The separated fatty acid has a solidifying-point of 18° to 23° , a refractive index at 40° of 1.454 to 1.458, an acid value of 195 to 205, and an iodine value of 83 to 92; it complies with tests for the absence of cottonseed oil, sesame oil and arachis oil. Hard soap complies also with limit tests for alkali hydroxide and free fatty acid, alkali carbonate, free fat, and for chloride and other alcohol-insoluble substances.

Action and Uses.—Hard soap is given internally in doses of 0.3 to 1 gramme (5 to 15 grains) as a cholagogue and laxative, also to increase the activity of other laxatives, such as aloin, ipomœa, jalap and rhubarb. Hard soap forms a basis for many pills and plasters. It is a useful pill excipient for resinous substances and volatile oils. Soap plaster is used as a protection for corns and bunions, and in place of plaster of colophony where the latter is too adhesive.

Preparations

Emplastrum Saponis, B.P.C.—(Emp. Sap.)—Plaster of Soap. Hard soap, about 1 in 7, with plaster of lead and colophony.

This plaster was included in the British Pharmacopœia, 1914.

Pilulæ Saponis cum Opio, B.P.C.—(Pil. Sap. c. Opio)—Soap Pills with Opium. *Syn.*—Pilulæ Saponis Compositæ; Compound Soap Pills. Each pill contains $\frac{1}{2}$ grain of powdered opium and about 1 grain of hard soap. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopœia, 1914, under the name of Pilula Saponis Composita.

SAPO KALINUS

(Sap. Kalin.)

Potash Soap

Synonym—Linseed Oil Soap.

Potash soap may be prepared by heating linseed oil with potassium hydroxide solution and a little alcohol until a small portion of the mixture is found to dissolve in boiling water without separation of oily drops. It occurs as a soft, unctuous, yellowish-brown mass, with a characteristic odour and an alkaline taste.

Soluble in water (1 in 4) and alcohol (1 in 1).

Standard.—Potash soap, determined by the method of the British Pharmacopœia for Sapo Mollis, yields not less than 44 per cent. of the fatty acids of linseed oil. It complies with the limit tests for chlorides and other alcohol-insoluble substances, alkali hydroxide, alkali carbonate, and free fatty acid in Sapo Mollis. The fatty acid obtained in the assay has an iodine value of 179 to 210.

Uses.—Potash soap is used in the preparation of liquid soaps which are preferred by some surgeons to preparations of soft soap for cleansing the skin before operations.

Preparation

Spiritus Saponis Kalini, B.P.C.—(Sp. Sap. Kalin.)—Spirit of Potash Soap. *Syn.*—Spiritus Saponis Kalini (Hebra). Potash soap, 65 per cent. w/v, in alcohol (90 per cent.), perfumed with oil of lavender.

SAP0 MOLLIS

(Sap. Moll.)

Soft Soap

Soft soap is a potassium soap prepared from olive oil, and consists chiefly of potassium oleate. It may be prepared by heating olive oil with potassium hydroxide and water. The soap cannot be precipitated by adding common salt, since this would react to form a sodium soap; hence the mixture is allowed to cool, and the product therefore contains the glycerin formed during saponification. Soft soap occurs as an almost odourless, unctuous substance, varying in colour from yellowish-white or yellowish-brown to green. The tint of soft soap depends on the olive oil employed in making it, but copper compounds and chlorophyll are sometimes added to produce an artificial green colour.

Soluble in water (1 in 4), boiling water (1 in 1) and alcohol (90 per cent.) (1 in 1).

Standard, B.P.—Soft soap yields not less than 44 per cent. of the fatty acids of olive oil, having the characters of the fatty acids described under Sapo Durus. It complies also with limit tests for chloride and other alcohol-insoluble substances, alkali hydroxide, alkali carbonate, free fatty acid, and free fat.

Action and Uses.—Soft soap is used to remove incrustations in chronic scaly skin diseases, such as psoriasis, and to cleanse the scalp previous to the application of antiseptic lotions. A solution in industrial methylated spirit, with the addition of methylated ether, is used by surgeons to cleanse the skin. For rectal administration to remove impacted fæces, a solution of 1 part of soft soap in 30 to 40 parts of warm water is employed. Linimentum Saponis is a mild counter-irritant used to rub sprains, contusions and rheumatic joints, and to dilute more active liniments.

Preparations

Linimentum Saponis, B.P.—(Lin. Sap.)—Liniment of Soap. Soft soap, 8 per cent. w/v, and camphor, 4 per cent. w/v, with oil of rosemary and distilled water, in alcohol (90 per cent.) or industrial methylated spirit suitably diluted.

Liquor Formaldehydi Saponatus, B.P.C.—(Liq. Formaldehyd. Sap.)—Solution of Formaldehyde with Soap. Soft soap, 1 in 2½, and solution of formaldehyde, 1 in 5, in alcohol (90 per cent.) and distilled water.

This solution was included in the British Pharmacopæia, 1914.

Liquor Saponis Æthereus, B.P.C.—(Liq. Sap. Æther.)—Ethereal Solution of Soap. *Syn.*—Ether Soap; Salutio Saponis Ætherea. A solution containing about 40 per cent. of potassium oleate in ether and alcohol (90 per cent.), with oil of lavender.

Liquor Saponis Antisepticus, B.P.C.—(Liq. Sap. Antisept.)—Antiseptic Solution of Soap. *Syn.*—Antiseptic Ethereal Soap; Solutio Saponis Antiseptica. Ethereal solution of soap with 0.05 per cent. w/v of mercuric iodide, and potassium iodide.

Spiritus Saponatus, B.P.C.—(Sp. Sap.)—Soap Spirit. Soft soap, 65 per cent., w/v, in alcohol (90 per cent.).

SAPONINUM**(Saponin.)****Saponin***Synonyms*—Quillaic Acid; Quillain.

Saponin is a colloidal glycoside or mixture of glycosides obtained from quillaia bark. The commercial article is a mixture obtained by boiling the powdered bark with water until exhausted, evaporating the decoction thus obtained to dryness, and boiling the extract with alcohol under a reflux condenser. This solution deposits the "saponin" on cooling, and the process of boiling and cooling may be repeated until the product is perfectly white. It occurs as an amorphous powder, having a sweetish, afterwards bitter, acrid taste, accompanied by a burning sensation; it is intensely irritating and sternutatory. The solubility in water is increased by the addition of a small amount of alkali. An aqueous solution (1 in 1000) froths like soap solution, the froth being very persistent, but easily dispersed by alcohol or ether. When treated successively with 2 drops of acetic anhydride and 1 drop of sulphuric acid, saponin develops a bright red colour. When boiled with dilute mineral acid, it hydrolyses and produces a sapogenin which is insoluble in water, and a quantitative process of determination is based on this reaction. Commercial saponin contains sucrose, quillaic acid and quillaia-sapotoxin, the last two substances being acrid and poisonous.

Soluble in water and hot alcohol; insoluble in ether, chloroform, benzene and carbon disulphide.

Action and Uses.—Saponin is a powerful irritant to the alimentary canal, and may give rise to toxic symptoms; it has a strongly hæmolytic action on the blood. It is not given medicinally, but is sometimes used to emulsify fixed and essential oils, liquid tar, etc., and as a foam stabiliser in contraceptive tablets and antiseptic stili. It is also used as a frothing agent for various technical purposes.

SAPPAN**(Sappan)****Sappan***Synonym*—Sappan Lignum.

Sappan is the heartwood of *Cæsalpinia Sappan* Linn. (Fam. Leguminosæ), a tree indigenous to India.

The wood occurs as orange-red, hard, compact, heavy pieces, sometimes with a little whitish sapwood adhering, or in orange-red chips; it has a close, straight grain, and readily splits longitudinally. A smoothed, transversely cut surface shows well-marked, regular concentric rings, diffusely scattered vessels, and numerous narrow

medullary rays. It is odourless, and has an astringent taste. When chewed, it colours the saliva red, and when lime water is added to a decoction of the wood, a crimson-red colour is developed.

Sappan **contains** a colourless, crystalline principle, brazilin, $C_{16}H_{14}O_5$, also obtained from brazil wood, and allied to hæmatoxylin. Solution of brazilin assumes a carmine-red colour in contact with even traces of caustic alkalis, whereas solution of hæmatoxylin becomes purple. Brazilin is soluble in both alcohol and water.

Action and Uses.—Sappan is used as an astringent in India and other parts of the Empire in place of logwood. It may be **administered** as Decoctum Sappan (1 in 20) in doses of 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

SARSA

(Sars.)

Sarsaparilla

Synonym—Sarsæ Radix.

Sarsaparilla consists of the dried root and rootlets of *Smilax ornata* Lem. (Fam. Liliacæ), a climbing plant growing in Costa Rica, and of *S. medica* Schecht and Cham., indigenous to Mexico. The former is known commercially as Jamaica, or Costa Rica, sarsaparilla, and the latter as Mexican sarsaparilla.

Jamaica sarsaparilla occurs in bundles about 45 centimetres long and 10 to 12 centimetres wide, consisting of numerous long, slender roots and fibrous rootlets, doubled up and bound loosely with a long root of the same plant. The roots are deeply furrowed longitudinally, almost free from transverse cracks, from 3 to 5 millimetres in thickness, reddish-brown in colour and very tough, breaking with difficulty. The transverse section shows a brown cortex, a yellowish lignified ring containing large xylem vessels, and a central parenchymatous pith which contains starch. Mexican sarsaparilla consists of portions of rhizome with roots attached; it is not made into bundles. The roots are dark grey in colour, with transverse cracks and deep, longitudinal wrinkles. The drug has a faintly bitter taste, but is without odour.

The diagnostic **microscopical** characters are the thick-walled cells of the exodermis; the cortical parenchyma, containing occasional starch grains and, in certain cells, bundles of raphides of calcium oxalate; the cells of the endodermis, measuring about 25 microns across, nearly square in transverse section, and having uniformly thickened walls in Jamaica sarsaparilla, and showing a horse-shoe thickening in Mexican sarsaparilla; the large vessels of the xylem.

Sarsaparilla **contains** sarsapaponin, $C_{44}H_{76}O_{20} \cdot 7H_2O$, a crystalline glycoside yielding sarsapogenin and dextrose on hydrolysis. Sarsapic

acid, dextrose, fatty acids and starch are also present. It yields to water from 10 to 20 per cent. of extractive; the ash is about 7 per cent.

Substitutes.—Honduras sarsaparilla occurs in bundles about 75 centimetres long and 5 to 6 centimetres wide, closely bound with a long root. It is yellowish-brown in colour, less wrinkled than Jamaica sarsaparilla and contains abundant starch in the cortex. Native Jamaica sarsaparilla, obtained from *S. officinalis* H.B. & K. and Cultivated in Jamaica, is pale reddish-brown in colour, bears a few stout rootlets and shows in transverse section a pale cortex separated from a darker stele by a distinct line. It is imported loose in large bales.

Action and Uses.—Sarsaparilla was formerly used in the treatment of chronic rheumatism, skin diseases and syphilis. It is now used as a vehicle, usually in the form of Decoctum Sarsæ Compositum.

Preparations

Decoctum Sarsæ Compositum, B.P.C.—(Dec. Sars. Co.)—Compound Decoction of Sarsaparilla. Sarsaparilla, 1 in 8, with sassafras root, guaiacum wood, mezereon, liquorice and distilled water. When compound decoction of sarsaparilla or Decoctum Sarsæ Compositum is prescribed, either Decoctum Sarsæ Compositum or Decoctum Sarsæ Compositum Concentratum suitably diluted may be dispensed. Dose.—60 to 240 millilitres (2 to 8 fluid ounces).

Decoctum Sarsæ Compositum Concentratum, B.P.C.—(Dec. Sars. Co. Conc.)—Concentrated Compound Decoction of Sarsaparilla. One part added to seven parts of distilled water yields a preparation which is approximately equivalent in strength to compound decoction of sarsaparilla, but contains about 2·8 per cent. v/v of alcohol (90 per cent.). Dose.—8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

SASSAFRAS

(Sassaf.)

Sassafras

Synonyms—Sassafras Cortex; Sassafras Bark.

Sassafras is the dried inner bark of the root of *Sassafras variifolium* (Salisb.) O. Kuntze (Fam. Lauracæ), a tree indigenous to the Eastern United States of America.

The drug occurs in cut or broken, channelled, flat or recurved pieces, or occasionally in quills. The pieces or quills are usually from 4 to 15 centimetres long, 1 to 3 centimetres wide, and from 0·5 to 3 millimetres thick. Both surfaces are from pale orange to reddish-brown; the outer surface is somewhat scaly, and bears prominent root-scars or pieces of roots, and occasional patches of grey cork; the inner surface is finely striated longitudinally. The fracture is shortly fibrous. The odour is aromatic, and the taste is aromatic, astringent and mucilaginous.

The diagnostic **microscopical** characters are the almost entire absence of cork cells; the presence in all parts of rounded starch grains up to 20 microns in diameter; the abundant oil cells; the numerous spindle-shaped, yellowish, isolated phloem fibres, about 25 microns in diameter and from 150 to 400 microns long, and having very thick, lignified walls; the absence of crystals of calcium oxalate.

Sassafras contains volatile oil, from 3 to 9 per cent., tannin, about 6 per cent., a reddish-brown, altered tannin compound, about 9 per cent., together with resin and starch.

Standard.—Sassafras contains not more than 2 per cent. of adhering wood and other foreign organic matter. Acid-insoluble ash, not more than 5 per cent.

Action and Uses.—Sassafras, by virtue of its volatile oil, has mildly aromatic and carminative properties.

SASSAFRAS MEDULLA.—Sassafras pith is the pith removed from the stem of *Sassafras officinale* Nees and Eberm. collected late in the autumn, after frost, and dried. It occurs in pieces up to 15 centimetres in length and about 5 millimetres in diameter; they are whitish and often curved or coiled, light in weight, and consist of a thin-walled lignified parenchyma. The drug contains mucilage and a trace of volatile oil. Sassafras pith has demulcent properties, and the mucilage prepared from it is sometimes used in eye lotions.

SASSAFRAS RADIX.—Sassafras root is the root of *Sassafras officinale* Nees and Eberm. It is a large, woody, branching root, usually sold in the form of chips and slices about 3 to 5 millimetres in thickness. It is greyish-brown in colour, ring-porous, and shows well marked annual rings; the bark is present in small amount. It contains about 2 per cent. of volatile oil.

SCAMMONIÆ RESINA

(Scammon. Res.)

Scammony Resin

Synonym—Resin of Ipomœa.

Scammony resin is a mixture of resins obtained from ipomœa. It may be extracted by percolating with alcohol. The alcohol is removed by evaporation, and the residual resin washed with boiling water and dried. It occurs in brownish, translucent fragments, breaking with a brittle, resinous fracture, or as a pale brown powder, having a sweet, fragrant, characteristic odour and an acrid taste. Scammony resin contains chiefly the methylpentosides and other glycosides of jalapinic acid and its methyl ester.

Soluble in alcohol (90 per cent.); wholly or partly soluble in ether; insoluble in water.

Standard, B.P.—Scammony resin loses, on drying at 100°, not more than 5 per cent. of its weight. Ash, not more than 0.5 per cent. Water-soluble matter, not more than 1 per cent. It complies also with tests for the absence of certain other resins and of colophony, and with a limit test for ether-insoluble resins.

Action and Uses.—Scammony resin is a drastic purgative, resembling jalap and colocynth. Its action is rapid, but it may cause nausea and vomiting. Large doses cause acute gastro-intestinal

irritation, with congestion of the pelvic organs. Absorption has been known to occur and to give rise to cystitis and nephritis. The action of scammony resin is greatly facilitated by administration with ox bile or sodium tauroglycocholate, which assists solution. It is employed, usually with other purgatives such as colocynth or jalap, to relieve cerebral congestion by lowering blood pressure, and to remove fluid in dropsical conditions. The resin is of service with anthelmintics, such as santonin, to remove thread-worms and round-worms. It is **administered** in pill form as *Pilulæ Scammonia Compositæ*, and in powders or cachets as *Pulvis Scammonia Compositus*. When prescribed in pills, an equal weight of soap should be added; this assists the preparation of the pill mass, promotes solution in the intestine, and enhances the purgative action of the drug.

Dose.—0·03 to 0·2 gramme ($\frac{1}{2}$ to 3 grains).

Preparations

Pilulæ Scammonia Compositæ, B.P.C.—(Pil. Scammon. Co.)—Compound Scammony Pills. Each pill contains 1 grain each of scammony resin, jalap resin and curd soap, and $\frac{1}{2}$ grain of ginger. Dose.—1 or 2 pills.

Pulvis Scammonia Compositus, B.P.C.—(Pulv. Scammon. Co.)—Compound Powder of Scammony. Scammony resin, 1 in 2, with jalap and ginger. Dose.—0·6 to 1·2 grammes (10 to 20 grains).

This powder was included in the British Pharmacopœia, 1914.

SCAMMONIUM

(Scammonium)

Scammony

Synonym—Virgin Scammony.

Scammony is a gum-resin obtained from the growing root of *Convolvulus Scammonia* Linn. (Fam. Convolvulaceæ). The crown of the root is cut off obliquely, and the emulsion, which exudes from cells in the parenchymatous tissue, is collected in a shell placed at the lower edge of the cut surface. The contents of the shells are collected, made into a cake and allowed to dry.

The drug occurs in large flat, dark grey to blackish pieces, or in irregular, flattened lumps which are easily broken; thin fragments are translucent and yellowish-brown. The fractured surface is glossy, and usually exhibits small cavities, probably the result of fermentation during the slow drying of the drug. The odour is faint but butyric, and the taste is slightly acrid. When triturated with water, it forms a white emulsion. Scammony **contains** resin, about 80 per cent., and gum; only traces of starch are present. The ash varies from about 3 to 6 per cent.

Substitutes.—Owing to the scarcity of genuine scammony, factitious substitutes are sometimes found in commerce; these may generally be detected by the absence of the butyric odour, high ash and sometimes by the presence of foreign starch. The presence of foreign resins may be detected by extracting the drug with ether and dissolving the ether extract in hot solution of potassium hydroxide; on acidifying, resin is not precipitated, although the solution may become opalescent from separation of fatty acids. Skilleep is a variety of scammony consisting of farinaceous dough mixed with some of the gum-resin.

Action and Uses.—The action of scammony resembles that of scammony resin. It is, however, miscible with water or milk, the resin forming an emulsion with the gum present.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

SCILLA

(Scill.)

Squill

Synonym—*Scillæ bulbos* I.A.

Squill consists of the bulb of *Urginea Scilla* Steinh. (Fam. Liliaceæ), divested of its outer, membranous scales and dried; it is indigenous to the Mediterranean region. The bulbs are collected in August, deprived of their roots and outer membranous scales, and the remaining fleshy scales are sliced and dried in the sun. Squill should be **stored** in well-closed containers; powdered squill should be kept quite dry in a desiccated atmosphere.

Squill occurs in curved or straight, angular pieces, tapering towards each end, about 0.5 to 5 centimetres long and 3 millimetres thick, of a yellowish-white colour, horny in texture, somewhat translucent, and breaking with an almost glassy fracture when quite dry, but readily absorbing moisture when exposed to the air, becoming tough and flexible. It is almost odourless; the taste is mucilaginous, disagreeably bitter and acrid.

The diagnostic **microscopical** characters are pieces of the epidermis of both surfaces showing only very occasional stomata; portions of the mesophyll, traversed by collateral vascular bundles having spiral and annular vessels, and consisting of thin-walled parenchyma containing occasional starch grains, large cells containing bundles of acicular raphides embedded in mucilage which stains pink with alkaline solution of corallin, individual crystals being up to about 1 millimetre long, and many cells containing dextrose.

A number of glycosides and bitter principles have been prepared from squill and given such names as scillitoxin, scillipicrin, scillin, scillain, scillitin, but none is regarded as a pure substance. Scillaren is a mixture of scillaren A and scillaren B. The former is a pure crystalline glycoside, $C_{37}H_{54}O_{13}$, which gives on hydrolysis scillaridin A, $C_{25}H_{32}O_3$, and a sugar, scillabiose. Scillaren B is a mixture of glycosides. Both

have a high physiological activity. Squill also contains mucilage, sinistrin (a carbohydrate), a phytosterol and calcium oxalate. It yields to alcohol (60 per cent.) about 65 per cent. of extractive.

Substitute.—A red variety of *Urginea Scilla* is used in French pharmacy in addition to the white variety of the British Pharmacopœia; it has a more intensely bitter taste. This red variety is also used for the manufacture of rat poison.

Standard, B.P.—Squill yields not more than 6 per cent. of ash. The British Pharmacopœia does not include a biological assay for squill and no standard is recommended by the Permanent Commission on Biological Standardisation of the League of Nations.

Squill, in powder (*Pulvis Scillæ* : *Pulv. Scill.*), contains the constituents and possesses the diagnostic microscopical characters of *Scilla*, and complies with the limit for ash of the unground drug.

Action and Uses.—Squill resembles digitalis in its action, but its effects on the heart and blood vessels are much more powerful; it increases the force of cardiac systole to a greater extent, and its action on the systemic blood vessels raises blood pressure to an extent which is unobtainable with digitalis. It also constricts the coronary vessels much more strongly than digitalis, and this is no doubt one reason which has rendered its value second to that of digitalis in therapeutics, because it is so essential in cardiac therapeutics to do all that is possible to improve the blood supply of the heart itself. It is given with digitalis in cardiac dropsy, also to promote absorption of effusions in the pleura and other serous cavities. Squill is more irritant than digitalis and not so readily absorbed, and it is for the latter reason that it is less suitable for general use in cardiac disease. In large doses it produces nausea and vomiting, and it was at one time used as an emetic. In smaller doses it mildly irritates the stomach and produces reflex secretion from the bronchioles; it is used mainly as an expectorant in the treatment of cough in chronic bronchitis.

The tincture is **administered** in mixture form with other expectorants, especially ipecacuanha and ammonium carbonate. Vinegar, oxymel and syrup of squill are also common constituents of expectorant cough mixtures. For use as a cardiac tonic in dropsy, squill is frequently given in pill form with mercury pill and digitalis (see *Pilulæ Digitalis Compositæ*). The powdered drug and extracts made from it have been largely used as rat poisons and are said to be very efficacious, the red variety being preferred for this purpose although there is not sufficient evidence of its superiority.

Dose.—0·06 to 0·2 grammie (1 to 3 grains).

Preparations

Acetum Scillæ, B.P.—(*Acet. Scill.*)—Vinegar of Squill. *Syn.*—*Acetum Scillæ* I.A. It contains active constituents equivalent to approximately 10 per cent. w/v of squill. Specific gravity, 1·031 to 1·035; it complies also with a test for limits for acidity. **Dose.**—0·6 to 2 millilitres (10 to 30 minims).

Extractum Scillæ Liquidum, B.P.C.—(*Ext. Scill. Liq.*)—Liquid Extract of Squill. 1 in 1. **Dose.**—0·06 to 0·2 millilitre (1 to 3 minims).

Linctus Diamorphinæ et Scillæ, B.P.C.—(Linct. Diamorph. et Scill.)—Linctus of Diamorphine and Squill. Each fluid drachm contains $\frac{1}{4}$ grain of diamorphine hydrochloride and $\frac{1}{10}$ grain of sodium antimonytartrate, with liquid extracts of senega and squill, glycerin and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linctus Scillæ, B.P.C.—(Linct. Scill.)—Linctus of Squill. *Syn.*—Linctus; Simple Linctus. Oxymel of squill, 1 in 4, with mucilage of tragacanth, glycerin, emulsion of chloroform and syrup. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Linctus Scillæ Compositus, B.P.C.—(Linct. Scill. Co.)—Compound Linctus of Squill. *Syn.*—Linctus Scillæ Opiatus; Opiate Linctus of Squill; Gee's Linctus. Equal parts of camphorated tincture of opium, oxymel of squill and syrup of tolu. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Oxymel Scillæ, B.P.—(Oxymel Scill.)—Oxymel of Squill. It contains active constituents equivalent to approximately 5 per cent. w/v of squill, with acetic acid, distilled water and purified honey. Specific gravity, about 1.27. Optical rotation at 20° of a 25 per cent. w/v solution in water, decolourised if necessary with charcoal, +0.6° to -1.9°. It complies also with a test for limits of acidity. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Oxymel Scillæ I.A. contains approximately the same proportion of squill and acetic acid, but a smaller proportion of honey.

Pilulæ Digitalis Compositæ, B.P.C.—(Pil. Digit. Co.)—Compound Digitalis Pills. *Syn.*—Pilulæ Digitalis cum Scilla; Guy's Pills; Niemeyer's Pills. Each pill contains 1 grain each of powdered digitalis, squill, and pill of mercury. Dose.—1 or 2 pills.

Pilulæ Ipecacuanhæ cum Scilla, B.P.C.—(Pil. Ipecac. c. Scill.)—Ipecacuanha Pills with Squill. Each pill contains 2 grains of powder of ipecacuanha and opium and $\frac{1}{2}$ grain each of squill and ammoniacum. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914, under the name of Pilula Ipecacuanhæ cum Scilla.

Pilulæ Scillæ Compositæ, B.P.C.—(Pil. Scill. Co.)—Compound Squill Pills. Each pill contains 1 grain of squill, about $\frac{1}{2}$ grain each of ginger and ammoniacum and about $\frac{1}{2}$ grain of hard soap. Dose.—1 or 2 pills.

The mass with which these pills are made was included in the British Pharmacopæia, 1914.

Syrupus Scillæ, B.P.—(Syr. Scill.)—Syrup of Squill. Vinegar of squill, 45 per cent. v/v, with sucrose and distilled water; it contains active constituents approximately equivalent to 4.5 per cent. w/v of squill. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Scillæ, B.P.—(Tinct. Scill.)—Tincture of Squill. *Syn.*—Tinctura Scillæ I.A. It is prepared by maceration with alcohol (60 per cent.), and contains active constituents equivalent to approximately 10 per cent. w/v of squill. Dose.—0.3 to 2 millilitres (5 to 30 minims).

SCOPARIUM

(Scopar.)

Scoparium

Synonyms—Broom Tops; Scoparii Cacumina.

Scoparium consists of the fresh or dried tops of *Cytisus scoparius* Link (Fam. Leguminosæ), a shrub indigenous to the British Isles and temperate Europe.

The stem is dark green, with long, erect, straight, slender, alternate branches which are from about 1 to 3 millimetres in diameter. The branches are tough, flexible and glabrous, and have five, winged, longitudinal ridges; they bear small, sessile, simple leaves near the tips and trifoliate, stalked leaves below. In the dry drug few leaves are present. The taste is bitter and unpleasant. The fresh drug, especially when bruised, has a characteristic odour which disappears on drying.

Scoparium **contains** the liquid, volatile alkaloid, sparteine, together with a small quantity of a crystalline, volatile alkaloid, genisteine, and a non-volatile alkaloid, sarothamnine. It also contains a yellow, crystalline substance, scoparin, belonging to the flavone group. It yields to alcohol (20 per cent.) about 16 per cent. of extractive. The ash is about 3 per cent.

Standard.—Scoparium contains not more than 5 per cent. of stem measuring more than 4 millimetres in diameter and not more than 2 per cent. of foreign organic matter.

Action and Uses.—Scoparium is employed as a mild diuretic, generally in dropsical complaints of cardiac origin. This action is due to the sparteine, although, like digitalis, it has little diuretic effect in normal health. It is **administered** in the form of decoction, infusion, or juice, often with squill and ammonium or potassium acetate. Infusion of scoparium is frequently used as a vehicle for the administration of other diuretics.

Preparations

Decoctum Scoparii, B.P.C.—(Dec. Scopar.)—Decoction of Scoparium. *Syn.*—Decoction of Broom. 1 in 20. When decoction of scoparium or Decoctum Scoparii is prescribed, either Decoctum Scoparii or Decoctum Scoparii Concentratum suitably diluted may be dispensed. Dose.—60 to 120 millilitres (2 to 4 fluid ounces).

Decoctum Scoparii Concentratum, B.P.C.—(Dec. Scopar. Conc.)—Concentrated Decoction of Scoparium. *Syn.*—Concentrated Decoction of Broom. 1 in 2½. One part added to seven parts of distilled water yields a preparation which is approximately equivalent in strength to decoction of scoparium, but contains about 3 per cent. v/v of alcohol (90 per cent.). Dose.—8 to 16 millilitres (2 to 4 fluid drachms).

Infusum Scoparii Concentratum, B.P.C.—(Inf. Scopar. Conc.)—Concentrated Infusion of Scoparium. *Syn.*—Concentrated Infusion of Broom. 1 in 1½. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of scoparium, and differs also in containing a small proportion of alcohol. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Infusum Scoparii Recens, B.P.C.—(Inf. Scopar. Rec.)—Fresh Infusion of Scoparium. *Syn.*—Fresh Infusion of Broom. 1 in 10. When infusion of scoparium or Infusum Scoparii is prescribed, fresh infusion not being specified, either Infusum Scoparii Recens or Infusum Scoparii Concentratum suitably diluted may be dispensed. Dose.—30 to 60 millilitres (1 to 2 fluid ounces).

This infusion was included in the British Pharmacopœia, 1914 under the name of Infusum Scoparii.

Mistura Potassii Acetatis Composita, B.P.C.—(Mist. Pot. Acet. Co.)—Compound Potassium Acetate Mixture. *Syn.*—Mistura Diuretica. Each fluid ounce contains 20 grains of potassium acetate, 30 minims of spirit of nitrous ether, 20 minims of tincture of hyoscyamus and 1 fluid drachm of juice of scoparium, with infusion of buchu. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Succus Scoparii, B.P.C.—(Succ. Scopar.)—Juice of Scoparium. *Syn.*—Juice of Broom. The juice expressed from fresh scoparium, mixed with one-third its volume of alcohol (90 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This juice was included in the British Pharmacopœia, 1914.

SCOPOLIA

(Scopolia)

Scopolia

Synonym—Scopola.

Scopolia is the dried rhizome of *Scopolia carniolica* Jacq. (Fam. Solanaceæ), a plant common in the region of the Carpathian mountains, especially in Roumania and Czecho-Slovakia.

The rhizome occurs in entire or longitudinally split pieces from about 2.5 to 10 centimetres long and 8 to 20 millimetres thick. The external surface is yellowish-brown to dark brownish-grey, finely and irregularly wrinkled longitudinally, obscurely annulate, more or less warty, and bears closely set, cup-shaped stem-scars on the upper surface. The fracture is short and sharp, and the smoothed, transverse section exhibits a narrow, brown cork, a yellowish bark about 1 millimetre thick, an indistinctly radiate wood and a horny central pith. It is odourless, and the taste is sweetish at first but afterwards bitterish and acrid.

Scopolia **contains** the alkaloid, hyoscyamine; it also contains hyoscyne and probably atropine, the total alkaloid varying from about 0.4 to 0.5 per cent.

Action and Uses.—Scopolia resembles belladonna in its properties and may be employed for similar purposes, but the drug itself is rarely used in medicine.

Dose.—0.06 to 0.12 gramme (1 to 2 grains).

SCUTELLARIA

(Scutellar.)

Scutellaria

Synonyms—Scullcap; Madweed.

Scutellaria consists of the dried tops of *Scutellaria galericulata* Linn. and *S. lateriflora* Linn. (Fam. Labiatæ), perennial herbs, the

former indigenous to the British Isles and Europe and the latter to the United States of America.

The dried tops are about 50 centimetres long with smooth, branched, quadrangular stems and opposite, petiolate or nearly sessile, ovate-lanceolate or ovate-oblong leaves about 5 centimetres long and with a serrate margin. The flowers are blue, about 6 millimetres long, in axillary, one-sided racemes. The calyx is bilabiate, closed in front, and the upper lip helmet-shaped. The taste is somewhat bitter, and the odour is slight.

Scutellaria **contains** a bitter, crystalline glycoside, scutellarin, and a small quantity of volatile oil.

Substitute.—*Scutellaria integrifolia* Linn. (Western scullcap) is distinguished by its bitter taste, pubescent leaves and its inflorescence, which is a terminal raceme.

Standard.—*Scutellaria* contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—*Scutellaria* is very rarely prescribed, but it has been used in neuralgia, hiccough, insomnia and nervous disorders. It is **administered** in the form of dry or liquid extract (1 in 1).

Dose.— 1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

SENEGA

(Seneg.)

Senega

Synonyms—Senega Radix; Senega Root.

Senega is the dried root of *Polygala Senega* Linn. (Fam. Polygalaceæ), a perennial, herbaceous plant indigenous to Southern Canada and the United States of America.

Senega has a knotty root-stock, up to about 4 centimetres wide, consisting of the remains of slender, aerial stems, buds, and purplish, scaly leaves, from which descends the tap-root, usually about 5 to 20 centimetres long. The latter bears one or more spreading, lateral roots and is usually tortuous, with rather angular bends, on the concave side of which may be seen a distinct keel following a slightly spiral course, sometimes for some distance, whilst the convex side is usually transversely wrinkled, especially in the upper region of the root. The fracture is short and splintery in the wood and smooth in the bark. The smoothed, transverse surface shows a thin layer of cork, a light brown bark and a central, whitish wood traversed by almost imperceptible medullary rays. Anomalous secondary thickening occurs, resulting in increased development of phloem in the region of the keel, where this is present, and the formation in the xylem of one or sometimes two wedges of parenchyma with their apices adjacent to the primary xylem. The odour is characteristic, recalling that of wintergreen, and

the taste is at first sweetish, but afterwards acrid. The powder is very irritating to the mucous membranes of the nose and throat, and the drug imparts to water the property of frothing.

The diagnostic **microscopical** characters are the parenchyma, containing oil but not starch; the xylem consisting of numerous, pitted tracheids and fewer pitted or reticulated, small vessels; the absence of sclerenchymatous fibres and cells, and calcium oxalate crystals.

Senega **contains** two glycosidal saponins, senegin and polygalic acid, which resemble, but are not identical with, quillaia-sapotoxin and quillaic acid. Polygalic acid is sternutatory and produces frothing, while senegin is decidedly toxic. It also contains about 5 per cent. of fixed oil. The ash is about 5 per cent. Senega yields to alcohol (20 per cent.), about 28 per cent. of extractive.

Varieties.—Western senega is a smaller variety with a crown about 1 to 1·5 centimetres wide; northern senega is ascribed to *Polygala Senega* var. *latifolia* Torr. and Gray, and consists of larger roots, but resembles the western variety in other respects.

Substitute.—White senega, or southern senega, is the root of *Polygala alba* Nutt.; it is smaller and more slender than western senega; it has a normal wood but no keel. The taste is much less acrid.

Standard, B.P.—Senega contains not more than 5 per cent. of stems and other foreign organic matter.

Senega, in powder (*Pulvis Senegæ* : *Pulv. Seneg.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—The action of senega is attributed to its saponin constituents, which are irritant to the gastric mucous membrane and give rise to a reflex secretion of mucus in the bronchioles. It is not absorbed into the system. Senega is employed, usually with other expectorants such as ipecacuanha, squill and ammonium carbonate, in chronic bronchitis. It is **administered** as infusion, liquid extract, or tincture.

Dose.—0·4 to 0·8 gramme (6 to 12 grains).

COCILLANA.—Cocillana, or Guapi bark, is the dried bark of *Guarea Rusbyi* Rusby (Fam. Meliaceæ), a tree indigenous to Bolivia. The bark occurs in flat or curved pieces, varying in length and width, and up to about 2 centimetres in thickness. The fissured outer surface is greyish-brown in colour, or orange-brown where the cork has been removed, and is often covered with greyish lichens. Internally, the bark is of a brown colour and is coarsely striated longitudinally. The drug has a characteristic odour and a somewhat astringent and nauseous taste. Cocillana contains an alkaloid, resin (about 2·5 per cent.), fixed oil (about 2·5 per cent.) and a crystalline hydrocarbon. The drug resembles ipecacuanha in its action and has been administered in the form of a liquid extract (1 in 1) as an expectorant. Dose.—0·5 to 1 gramme (8 to 15 grains).

Preparations

Extractum Senegæ Liquidum, B.P.—(*Ext. Seneg. Liq.*)—Liquid Extract of Senega. 1 in 1. It is prepared with alcohol (60 per cent.), and made slightly alkaline with dilute solution of ammonia. Dose.—0·3 to 1 millilitre (5 to 15 minims).

Infusum Senegæ Concentratum, B.P.—(Inf. Seneg. Conc.)—Concentrated Infusion of Senega. Senega, 1 in 2½, extracted with alcohol (25 per cent.). The product is made faintly alkaline with dilute solution of ammonia. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of senega, and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

A concentrated infusion, prepared with dilute chloroform water and alcohol (90 per cent.) and containing also oil of sweet birch, was included in the British Pharmaceutical Codex, 1923.

Infusum Senegæ Recens, B.P.—(Inf. Seneg. Rec.)—Fresh Infusion of Senega. Senega, 1 in 20. Dose.—15 to 30 millilitres (½ to 1 fluid ounce).

Tinctura Senegæ, B.P.—(Tinct. Seneg.)—Tincture of Senega. Liquid extract of senega, 20 per cent. v/v, in alcohol (60 per cent.). Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

SENNÆ FOLIUM

(Senn. Fol.)

Senna Leaf

Senna leaf consists of the dried leaflets of the paripinnate leaves of *Cassia acutifolia* Delile, known in commerce as Alexandrian senna, and of *C. angustifolia* Vahl, known in commerce as Tinnevely senna (Fam. Leguminosæ), the former indigenous to and to some extent cultivated in the regions of the middle and upper Nile, the latter cultivated in India.

The leaflets are lanceolate to ovate-lanceolate, about 2 to 5 centimetres long and 0.5 to 1.6 centimetres wide, pale greyish-green or yellowish-green in colour, thin and brittle in texture, unequal at the base, and covered with a very short, fine pubescence, visible under a lens. The margin is entire and slightly incurled, the apex acute and mucronate, and the base very shortly stalked. The veins are more distinct on the under surface. The odour is slight, and the taste mucilaginous, slightly bitter and characteristic.

The diagnostic **microscopical** characters are the epidermises of both surfaces, composed of straight-walled, polygonal cells with rubiaceous stomata and conical, unicellular, thick-walled, warty trichomes which are frequently curved near the base; the presence of mucilage, filling the inner half of many of the epidermal cells; the isobilateral mesophyll, with palisade cells in a single layer on each surface and having wavy radial walls on the lower surface; above and below the veins, groups of pericyclic fibres flanked externally by a sheath of cells each containing a single prism of calcium oxalate; the cluster-crystals of calcium oxalate found in some cells of the interneural mesophyll.

Senna leaf **contains** rhein, aloë-emodin, kempferol and isorhamnetin, all four substances occurring both free and in the form of glycosides; myricyl alcohol, salicylic acid and a phytosterolin are also present. The drug contains in addition mucilage, calcium oxalate, resin and amorphous

glycosidic material. Senna leaf yields to cold water about 30 to 40 per cent. of extractive.

Varieties.—Alexandrian senna leaflets are pale greyish-green and ovate-lanceolate; they are usually slightly curved and twisted, and are brittle and often broken; the vein islet number is 25 to 30. Tinnevely senna leaflets are yellowish-green and lanceolate, flat, mostly unbroken and usually rather larger than the Alexandrian variety; the vein islet number is 20 to 23. They are less pubescent than Alexandrian senna, and are marked by occasional oblique and transverse lines produced by the hydraulic pressure used in packing the bales.

Substitutes.—Leaflets of *C. obovata* Collad., known as "dog senna," are distinguished by their obovate shape and, microscopically, by the papillose cells of the lower epidermis. Leaflets of *C. montana* Hayne, which are darker in colour, have a rounded apex and a dark network of veins. Leaflets of *C. angustifolia*, growing wild in Arabia, known as Arabian or Mecca senna, are narrow, lanceolate and usually discoloured. Palthé senna, from *C. auriculata* Linn., consists of small oblong to obovate leaflets, which are coloured crimson by 80 per cent. v/v sulphuric acid. Leaflets of *C. holosericea* Fresen. are small and hairy. Argel leaves, derived from *Solenostemma Argel* Hayne (Fam. Apocynaceæ), have been found admixed with Alexandrian senna, and occasionally the dehiscent follicles and plumed seeds are also present; the texture of the leaves is thick and rigid. They are peculiarly curled, curved, or twisted; the surface is finely wrinkled, and the veins are not evident. The leaf is equal at the base, the hairs are three-celled, and the taste is distinctly bitter.

Standard, B.P.—Senna leaf contains not more than 1 per cent. of stalks and not more than 2 per cent. of other foreign organic matter. Ash, not more than 12 per cent. Acid-insoluble ash, not more than 3 per cent.

Senna leaf, in powder (*Pulvis Sennæ Folii* : *Pulv. Senn. Fol.*), contains the constituents and possesses the diagnostic microscopical characters of *Sennæ Folium*, and complies with the limits for ash and acid-insoluble ash of the unground drug.

Action and Uses.—Senna leaf has an action similar to that of the fruit, but the latter is considered to be less griping. It is free from after-astringent action, but, on account of its tendency to gripe, is usually given with carminatives. It is a suitable laxative for the use of children and delicate persons and, in the form of *Confectio Sennæ*, is especially valuable in hæmorrhoids. Senna leaf may be **administered** as an infusion (1 in 10) in doses of 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

Dose.—0.6 to 2 grammes (10 to 30 grains).

Preparations

Confectio Sennæ, B.P.—(*Conf. Senn.*)—Confection of Senna. Senna leaf, about 10 per cent., with coriander, fig, tamarind, cassia, prune, extract of liquorice, sucrose and distilled water. Dose.—4 to 8 grammes (1 to 2 drachms).

Confectio Sennæ et Sulphuris, B.P.C.—(*Conf. Senn. et Sulphur.*)—Confection of Senna and Sulphur. Confection of senna and confection of sulphur, equal parts. Dose.—4 to 8 grammes (1 to 2 drachms).

Tinctura Sennæ Composita, B.P.C.—(*Tinct. Senn. Co.*)—Compound Tincture of Senna. Senna leaf, 1 in 5, caraway and coriander, of each, 1 in 40. Dose.—For repeated administration, 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm); for a single administration, 8 to 16 millilitres (2 to 4 fluid drachms).

This tincture was included in the British Pharmacopœia, 1914.

SENNÆ FRUCTUS

(Senn. Fruct.)

Senna Fruit*Synonym*—Senna Pod.

Senna fruit consists of the dried, ripe fruits of *Cassia acutifolia* Delile, known in commerce as Alexandrian senna pods, and of *C. angustifolia* Vahl, known in commerce as Tinnevely senna pods, (Fam. Leguminosæ); the former plant is indigenous to and cultivated in the regions of the middle and upper Nile, the latter cultivated largely in India.

Alexandrian senna pods are pale green to greenish-brown, with a brown central zone where the positions of the seeds are indicated by slight swellings; they are flattened laterally, rounded-oblong to feebly reniform in shape and of a parchment-like texture. The apex is rounded, with a slightly projecting point which is the base of the style; the base is cuspidate, sometimes shortly stalked, and the length of the pod varies from 3 to 6 centimetres and the width from 2 to 2·5 centimetres. Each pod contains about 5 to 7 flat, obovate-cuneate, hard seeds about 5 to 6 millimetres long, having a wrinkled, whitish-green surface and a short, raised ridge on each side at the pointed end. Tinnevely senna pods are usually darker, slightly narrower (not more than 2 centimetres wide) and somewhat straighter than the Alexandrian, and the remains of the base of the style are usually more pronounced. The average weight of a single senna pod is about 0·16 gramme (2½ grains). Senna fruit appears to **contain** the same active constituents as the leaf. It yields to cold water about 18 to 30 per cent. of extractive.

Standard, B.P.—Senna fruit contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Senna fruit is an efficient purgative either for occasional use or in habitual constipation. Its action is exerted on the large intestine. Like other members of this group it should be given with care during pregnancy. It is free from the after-astringent action of rhubarb, but, on account of its tendency to gripe, it is usually combined with carminatives and other laxatives. Preparations made from the fruit, without bruising the seed, are said to be less griping than those prepared from senna leaf. It is usually **administered** in the form of infusion or syrup, either of which is a suitable laxative for children and delicate persons. Mistura Sennæ Composita is a brisk purgative. The urine of patients taking senna preparations may be turned a yellow colour which changes to red on the addition of an alkali.

Dose.—0·6 to 2 grammes (10 to 30 grains), or 4 to 12 pods.

Preparations

Elixir Sennæ, B.P.C.—(Elix. Senn.)—Elixir of Senna. *Syn.*—Liquor Sennæ Leguminorum Dulcis; Sweet Essence of Senna Pods. Liquid extract of senna, 1 in 2, with sucrose, chloroform, oil of coriander, tincture of capsicum, alcohol (90 per cent.) and distilled water. **Dose.**—2 to 4 millilitres (½ to 1 fluid drachm).

Extractum Sennæ Liquidum, B.P.—(Ext. Senn. Liq.)—Liquid Extract of Senna. 1 in 1. It is prepared with chloroform water, concentration being effected under reduced pressure at a temperature not exceeding 60°, and preserved with one-quarter of its volume of alcohol (90 per cent.). Dose.—0.6 to 2 millilitres (10 to 30 minims).

A liquid extract prepared with a diluted alcohol was included in the British Pharmaceutical Codex, 1923.

Infusum Sennæ Concentratum, B.P.—(Inf. Senn. Conc.)—Concentrated Infusion of Senna. Senna fruit, 1 in 1½, extracted with alcohol (20 per cent.), the product being mixed with 8 per cent. v/v of strong tincture of ginger. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of senna, and differs also in containing a small proportion of alcohol. Dose.—2 to 8 millilitres (½ to 2 fluid drachms).

A concentrated infusion, prepared with dilute chloroform water and alcohol (90 per cent.), and containing less strong tincture of ginger, was included in the British Pharmaceutical Codex, 1923.

Infusum Sennæ Recens, B.P.—(Inf. Senn. Rec.)—Fresh Infusion of Senna. Senna, 1 in 10, and ginger, 1 in 200. Dose.—15 to 60 millilitres (½ to 2 fluid ounces).

Mistura Sennæ Composita, B.P.—(Mist. Senn. Co.)—Compound Mixture of Senna. *Syn.*—Black Draught. Magnesium sulphate, 25 per cent. w/v, with liquid extract of liquorice, compound tincture of cardamom, aromatic spirit of ammonia and infusion of senna. Dose.—30 to 60 millilitres (1 to 2 fluid ounces).

Syrupus Ficorum Compositus, B.P.C.—(Syr. Fic. Co.)—Compound Syrup of Figs. *Syn.*—Syrupus Ficorum Aromaticus; Aromatic Syrup of Figs. Compound tincture of rhubarb, 1 in 20, liquid extract of senna, 1 in 10, and elixir of cascara sagrada, 1 in 20, in syrup of figs. Dose.—2 to 8 millilitres (½ to 2 fluid drachms).

Syrupus Sennæ, B.P.—(Syr. Senn.)—Syrup of Senna. Liquid extract of senna, 25 per cent. v/v, with oil of coriander, sucrose and distilled water. Dose.—2 to 8 millilitres (½ to 2 fluid drachms).

SERIPARIUM

(Seripar.)

Rennet

Synonym—Rennin.

Rennet is the partially purified milk-curdling enzyme obtained from the glandular layer of the fourth or true digesting stomach of the calf. The stomachs are freed from superfluous matter such as outer skin, useless membrane and fat, washed, treated with salt and dried. The dried stomachs are comminuted and the rennet is extracted by means of a 5 per cent. solution of sodium chloride. From the solutions thus obtained the rennet may be precipitated by full saturation with sodium chloride, collecting and drying the precipitate. Rennet so obtained contains appreciable quantities of sodium chloride.

Rennet occurs as a greyish-white or yellowish-white powder, or as pale yellow grains or scales, having a characteristic and slightly saline taste. It is slightly hygroscopic. It is slowly soluble in water and in diluted alcohol, the solutions being more or less opalescent. When mounted in water or diluted alcohol and examined microscopically, it shows no cellular structure and produces no blue colouration on the addition of iodine solution. Rennet deteriorates rapidly, and must be kept in well-stoppered, amber-coloured bottles, and **stored** in a cool place. Rennet heated for ten minutes at 38° at pH 7.25 loses approximately only half its clotting power, whereas that of pepsin under similar conditions is almost completely destroyed.

Standard.—Rennet coagulates not less than 25,000 times its weight of fresh cows' milk when tested by the following method:—Mix 0.1 gramme of rennet with 50 millilitres of distilled water by gently stirring or triturating, and allow the liquid to stand for exactly fifteen minutes. Place 50 millilitres of milk, having an acidity to phenolphthalein equivalent to not less than 0.14 and not more than 0.15 per cent. of lactic acid, in a beaker about 12 centimetres high and 5 centimetres in diameter. Warm the milk rapidly on a water-bath to 43° , add 1 millilitre of the rennet solution and stir the mixture slowly for ten seconds. Maintain the temperature at 43° until the milk begins to thicken, as shown by a distinctly convex surface when the beaker is tipped to an angle of about 45° . The thickening must take place within ten minutes from the time of the addition of the rennet solution. An additional thirty seconds on the water-bath produces a firm curd.

Action and Uses.—Rennet is not used in medicine; it is employed in culinary operations to prepare easily digestible milk curds and in the manufacture of cheese. On the addition of rennet to milk, at a temperature of 38° , coagulation occurs. The coagulum consists of casein and the fat of the milk is associated with it. The whey contains lactalbumen, lactose and the salts of milk (chiefly calcium phosphate). Coagulation of milk involves two processes, (a) the conversion of caseinogen into paracasein and (b) the precipitation of the paracasein by the calcium salts contained in the milk. Hence milk in which the effective calcium content has been diminished either by dilution, boiling, the addition of sodium citrate or alkali, or dialysis, either does not coagulate or gives a small, flocculent clot on the addition of rennet. The rennin enzymes are ubiquitous. In fact, a rennin enzyme is present wherever proteolytic enzymes have been identified. For this reason it is now generally assumed that the coagulation of milk by gastric rennin is due to the action of pepsin and that the coagulation of milk by pancreatic rennin is due to the action of trypsin. It may be observed, however, that in order that pancreatic rennin (trypsin) may coagulate milk the calcium content of the milk must be raised to 4 per cent. by the addition of a soluble calcium salt. For this reason the existence of pancreatic rennin has been denied by many observers. Rennet may be used in the form of tablets.

SERPENTARIA

(Serpent.)

Serpentary

Synonyms—Serpentariæ Rhizoma; Serpentry Rhizome; Red River Snake Root; Texan Snake Root.

Serpentary consists of the dried rhizome and roots of *Aristolochia reticulata* Nutt. (Fam. Aristolochiaceæ), a small herbaceous plant with a perennial rhizome, indigenous to the United States of America and collected mainly in Texas.

The rhizome is about 2 centimetres long and 3 millimetres in thickness with numerous long, curved, but not matted, roots attached. It bears on the upper surface cup-shaped scars and short bases of aerial stems. The fracture is short and the fractured surface shows an eccentric pith situated nearer the upper surface, wide curved medullary rays, and a narrow brown bark. The roots, which are from 8 to 10 centimetres long and about 1.5 millimetres thick, are not shrivelled, and have a short fracture, the fractured surface showing a small, yellow wood and a thick, white bark. The drug is yellowish-brown in colour and has a camphoraceous odour and an acrid, bitter taste.

The diagnostic **microscopical** characters are the thin cork; the parenchymatous cortex containing starch grains from 3 to 15 microns in diameter, either single or compound; the occasional bast fibres; the xylem consisting of vessels up to 40 microns wide and wood fibres; the medullary rays about 4 to 8 cells wide, lignified and containing starch. The cells of the parenchymatous pith are pitted and lignified and contain starch. Calcium oxalate is absent.

Serpentary **contains** volatile oil (about 1 per cent.), tannin and a bitter principle, apparently an alkaloid, which crystallises in light yellow needles. The drug yields to alcohol (60 per cent.) about 14 per cent. of extractive.

Substitute.—Virginian snake root, from *A. Serpentaria* Linn., resembles the Texan variety, but has a shorter and thinner rhizome, and thinner, wiry, interlacing roots forming matted masses.

Standard, B.P.—Serpentary contains not more than 10 per cent. of its sub-aerial stems and not more than 2 per cent. of other foreign organic matter. Ash, not more than 10 per cent.

Serpentary, in powder (Pulvis Serpentariæ : Pulv. Serpent.), contains the constituents and possesses the diagnostic microscopical characters of Serpentaria, and complies with the limit for ash of the unground drug.

Action and Uses.—Serpentary is a bitter which is used to excite the gustatory nerve endings and so, reflexly, to influence gastric secretion, and is employed with mineral acids and other bitters in dyspepsia. The infusion is a useful vehicle for tonic mixtures. Serpentary is used in the preparation of compound tincture of cinchona.

Dose.—0.05 to 0.1 gramme ($\frac{3}{4}$ to $1\frac{1}{2}$ grains).

INULA.—Elecampane consists of the dried rhizome and roots of *Inula Helenium* Linn. (Fam. Compositæ). The drug consists chiefly of long, slightly tapering roots about 0.5 to 2 centimetres thick, the larger ones having been longitudinally sliced. The roots are light grey in colour, hard and horny. The fracture is short and the smoothed, transverse surface exhibits an indistinctly radiate wood separated from the cortex by a darker cambium line. In both wood and cortex large, scattered, dark brown, shining oil glands are visible. The rhizome is usually in thin, irregularly rounded slices 4 to 5 centimetres in diameter. The drug has an agreeable, aromatic odour and an aromatic, slightly bitter taste. Elecampane contains a bitter principle and inulin, and on distillation with water the drug yields from 1 to 2 per cent. of a crystalline mass mixed with a little volatile oil. It has been used in the form of decoction (1 in 40) or liquid extract (1 in 1) in the treatment of bronchitis.

Preparations

Infusum Serpentariæ Concentratum, B.P.C.—(Inf. Serpent. Conc.)—Concentrated Infusion of Serpentary. 1 in 2½. When infusion of serpentary or Infusum Serpentariæ is prescribed, this concentrated infusion diluted with seven times its volume of distilled water may be dispensed. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Tinctura Serpentariæ, B.P.C.—(Tinct. Serpent.)—Tincture of Serpentary. 1 in 5. Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

This tincture was included in the British Pharmacopœia, 1914.

SERUM ANTIBOTULINUM

(Serum Antibotulin.)

Anti-botulinus Serum

Synonym—Botulinus Antitoxin.

Anti-botulinus serum consists of the blood serum of horses which have been rendered immune by repeated injections of the specific bacterial exotoxin obtained from cultures of *Clostridium botulinum* (*Bacillus botulinus*). This micro-organism is an anærobic, spore-forming bacillus, normally found in soil. There are two types of *C. botulinum*, designated A and B, and these produce different toxins. The antitoxin to toxin A has no effect on toxin B, and vice versa. Anti-botulinus serum should be **stored** between 3° and 15°. Under these conditions it will retain its potency for about three months. It should be issued in sterilised **containers** sealed so as to exclude bacteria. If the containers permit the withdrawal of less than the entire contents, the antitoxin should contain a preservative not less potent than 0.5 per cent. of phenol. The label of the container should indicate the date beyond which the antitoxin is not intended to be used.

Action and Uses.—Botulism is a condition of acute toxæmia characterised by paralysis of cranial motor nerves and of the diaphragm. It is due to the botulinus toxin present in the infected food at the time it is consumed. The affinity of this toxin for nervous tissue resembles that of tetanus toxin and is broken with equal difficulty. Botulinus toxin is an extremely powerful poison. The

earliest symptoms of its action are blurred or double vision, giddiness, ptosis, and difficulty in swallowing and in speaking. In most cases of botulism the food responsible is definitely abnormal in appearance and odour, but in occasional cases no evidence of spoilage can be detected. Canned, smoked and pickled foods, which are liable to soil contamination during the process of manufacture, are the main sources of botulism. Anti-botulinus serum has not yet been proved to be effective in the treatment of human cases, but since no other effective treatment is known, it should be given a trial in a case of botulism. No success can be expected from the serum treatment unless it is given in the early stages of the disease. Persons who have consumed suspected food and in whom symptoms have not developed should receive an injection of serum as a prophylactic.

Dose.— Large doses, 30 to 50 millilitres (450 to 750 minims), of the polyvalent serum, or preferably of the monotypical serum if the type intoxication is known, should be given intravenously every day until recovery occurs or the clinical condition is hopeless. For a prophylactic dose, 10 millilitres may be given intramuscularly.

SERUM ANTIDYSENTERICUM (SHIGA)

(Serum Antidysenteric. (Shiga))

Anti-dysentery Serum (Shiga)

Anti-dysentery serum (Shiga) consists of the serum of animals, or a preparation of the serum, containing the immunising substances which have a specific therapeutic value when injected into persons infected with *Bacillus dysenteriae* (Shiga). The animals are immunised by the injection of cultures or of sterile filtrates from cultures of *B. dysenteriae* (Shiga). When a satisfactory degree of immunisation has been effected, a quantity of blood is withdrawn, allowed to clot, and the serum collected. It may be used in the liquid form or dried. The globulins containing the specific immunising substances may be separated from the serum by fractional precipitation and the precipitate may be used in solution or dried. Both liquid forms may contain an antiseptic.

The serum occurs as a yellow or yellowish-brown liquid or, in the solid condition, as a yellowish-white powder or yellow or yellowish-brown flakes. The solution of the globulins is of a yellowish-brown or greenish-yellow colour. Both liquid forms are transparent when first made, but become faintly opalescent when stored; they are almost odourless except for any odour due to the added antiseptic. The solution of the globulins does not contain more than 20 per cent. w/v of solid matter and the liquid serum does not contain more than 10 per cent. w/v of solid matter. The dried globulins resemble the dried serum in appearance and 10 per cent. w/v solutions of the dried forms resemble the liquid forms. The solid forms do not contain any added

antiseptic or other substance. In whatever form the product is obtained it should be **stored** in sterilised glass containers sealed so as to exclude bacteria and kept at as low a temperature above its freezing point as possible. The number of units in each container is sufficient to ensure that the number stated on the label is still present at the end of the period during which the preparation is intended to be used. The label on the **container** or the package states the nature of the contents and the date after which it is not intended to be used. The label on the container states the minimum total number of units in the container and also the number of units in one millilitre or in one gramme, or the total number of millilitres of a liquid or grammes of dried product in the container.

Standard, B.P.—All forms of anti-dysentery serum (Shiga) comply with the tests for sterility and with tests for freedom from abnormal toxicity prescribed by the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Bacilli of the dysentery group have been shown to be associated with certain forms of summer diarrhoea of children, and with asylum and institutional dysentery. Anti-dysentery serum possesses valuable prophylactic and curative properties against these conditions; it is of course useless in the treatment of amœbic dysentery. The effect of the treatment is seen in a reduction of the number of the stools, which in successful cases falls to normal in twenty-four hours. The treatment should, however, be continued for two days after this normal condition has been attained. Some cases of ulcerative colitis have been treated with doses of 100 millilitres of anti-dysentery serum intravenously.

Dose.—4000 to 10,000 units, by injection.

POLYVALENT ANTI-DYSENTERY SERUM, prepared from the serum of horses which have been immunised to more than one strain of the dysentery bacillus, is sometimes used instead of the monovalent serum. Such sera are designated by the names of the strains from which they are prepared, such as Anti-dysentery serum (Shiga-Flexner-Y.) or (Shiga-Flexner-Sonne-Y.).

SERUM ANTIMENINGOCOCCICUM

(Serum Antimeningococcic.)

Anti-meningococcus Serum

Anti-meningococcus serum is the serum obtained from the blood of horses which have been immunised against strains of the meningococcus (*Diplococcus intracellularis meningitidis* Weichselbaum or *Neisseria meningitidis*), isolated from different sources. The meningococcus is a small, gram-negative, intracellular diplococcus which is present in large numbers in the meninges of the brain and spinal cord and in the cerebrospinal fluid of cases of meningococcal meningitis. Four serological types of the meningococcus are known. These are designated by the classification of Gordon, types I, II, III and IV, and the serum

is usually prepared by immunising the horses to all four types. Anti-meningococcus serum as ordinarily prepared is thus a polyvalent serum. According to the classification of Griffith, Group I corresponds to Gordon's types I and III, and Group II corresponds to Gordon's types II and IV. The serum as usually prepared, by immunising the horses to either live or dead cultures of the organism, is antibacterial rather than antitoxic in character, and contains agglutinins, bacteriolysins and anti-endotoxins. It has been shown, however, that, contrary to the previously accepted belief, the meningococcus produces an extracellular toxin and it is possible to prepare a specific antitoxin.

Anti-meningococcus serum is a pale coloured, slightly opalescent liquid with no characteristic odour other than that of the preservative which may be added. Anti-meningococcus serum should be **stored** between 5° and 15° in sterile containers sealed so as to exclude bacteria. The label on the **container** states the date beyond which the serum should not be used and the amount and nature of the preservative.

Standard.—Anti-meningococcus serum complies with the tests for sterility and freedom from abnormal toxicity prescribed in the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Anti-meningococcus serum has proved of much value in the treatment of meningococcal meningitis, and its use should never be neglected in any case of the disease, although good results usually accrue only from its administration in the early stages. It is of no value in meningitis caused by other organisms. In meningococcal meningitis it should be given both intravenously and intrathecally for the first few doses; later the intravenous dose may be omitted. For intrathecal injection, a volume of cerebrospinal fluid larger than the volume of the dose of serum must be drawn off by lumbar puncture and the serum—which should be warmed to the body temperature—immediately injected very slowly. The serum must be injected intrathecally at least once a day for the first five days, no matter what the clinical condition may be. If intrathecal injection is not possible, the serum should be administered intracisternally, the same precautions being observed. The dosage must be regulated according to the age and clinical condition of the patient. Adults will tolerate larger doses than infants, and in acute cases greater risks may be taken than in mild cases. In cases of medium severity the adult dose should be 20 to 30 millilitres given intrathecally once a day, with one or more doses of 20 to 30 millilitres given intravenously during the first one or two days. In severe cases the intrathecal dose should be 20 to 30 millilitres given twice in the first twenty-four hours and thereafter once a day, with two or more doses of 20 to 30 millilitres given intravenously. For infants under one year of age it is not advisable to inject more than 10 millilitres for an intrathecal dose, but the dose may be repeated. The serum may also be employed intramuscularly as a prophylactic treatment for contacts in doses of 15 millilitres.

Dose.— 10 to 30 millilitres by intrathecal or intravenous injection.

extended to twelve hours if treatment is begun during the first three days. The effects of early serum treatment in cases of primary pneumonia are shown by a rapid fall in temperature and the progressive disappearance of all signs of toxæmia. The disappearance of cyanosis is a particularly marked feature after the first or second dose. The physical signs indicating the course of the inflammatory processes undergo a rapid change, corresponding with the effect of the serum in relieving symptoms. The viscid, blood-stained, rusty sputum, typical of early pneumonia, changes to a loose, purulent expectoration. A preliminary test for sensitivity is desirable to prevent anaphylactic reactions and, in the case of a positive reaction, desensitisation should be attempted by the intravenous injection of a small dose of serum, or adrenaline hydrochloride solution (3 to 8 minims) may be injected before the serum is administered. It is used also in primary pneumococcal meningitis and primary pneumococcal peritonitis.

Dose.—10,000 or 20,000 units, by injection.

SERUM ANTISTREPTOCOCCICUM

(Serum Antistreptococcic.)

Anti-streptococcus Serum

Anti-streptococcus serum consists of the blood serum of horses which have been immunised against a large number of strains of streptococci isolated from a variety of streptococcal infections, such as erysipelas, endocarditis, puerperal fever and acute otitis media. The serum so obtained is a polyvalent, antibacterial serum with very little antitoxic power. A serum that is antitoxic as well as antibacterial may be prepared by immunising the horses against the toxins of the micro-organisms as well as against the cultures themselves. The antitoxic and antibacterial substances may be separated by fractional precipitation and used in solution. It contains 0.5 per cent. of phenol or other suitable antiseptic.

Standard.—Anti-streptococcus serum complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Anti-streptococcus serum is used for the treatment of streptococcal infections such as general septicæmia, infective endocarditis, wound infections, etc. It is also used in scarlet fever, erysipelas and puerperal septicæmia, but in these diseases serum prepared from the specific strain of streptococcus is generally preferred. Early administration and adequate dosage of the serum are necessary; the possibility that the patient may have been sensitised by a previous dose of horse serum should be borne in mind and in cases of sensitisation the procedure described under Serum Antipneumococcicum should be followed. The action of anti-streptococcus serum is erratic; sometimes it may exert little or no beneficial effect,

but occasionally its early administration results in a prompt and dramatic recovery. This possibly occurs when the strain of streptococcus responsible for the particular infection under treatment is identical with one of the strains employed in the manufacture of the serum. In acute and septicæmic cases the serum should be given intravenously in doses of 10 to 30 millilitres, repeated daily if necessary. In subacute cases 10 to 20 millilitres should be injected intramuscularly.

Dose.—10 to 30 millilitres (150 to 450 minims), by intravenous or intramuscular injection.

SERUM ANTIVENENOSUM

(Serum Antivenenos.)

Anti-venom Serum

Synonyms—Antivenene; Snake Venom Antitoxin.

Anti-venom serum consists of the blood serum of horses which have been immunised by subcutaneous injections of snake venom. The poisonous snakes belong chiefly to the Colubrine and the Viperine families. To the former belong the cobras, the coralline snakes, the kraits, the hamadryad and the death-adder. To the latter belong the common viper, the puff-adder, the rattlesnake, bush-master and the copperhead. The poisonous water-snakes are classed as Colubrine snakes. In recent years much evidence has been brought forward to show that a serum prepared from a colubrine venom will not neutralise a viperine venom, and vice versa. Moreover, there appears to be a high degree of generic specificity among the snake venoms, so that, for example, a serum prepared for use against cobra venom will not completely neutralise the venom of the death-adder. Theoretically it should be possible to prepare a polyvalent anti-venom, but in practice this is not possible because of the extreme toxicity of mixed venoms. Of the numerous anti-venom sera available that prepared by Calmette's method from a mixture of 80 per cent. cobra poison with 20 per cent. viperine venom is probably the most efficient for general use.

Standard.—Anti-venom serum complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—A monovalent anti-venom serum undoubtedly does exert both a curative and a protective action, but, as most patients are unable to identify the snake that has bitten them (most snake bites occur during the night or in the dusk of the evening), a monovalent anti-venom serum can only rarely be used. Moreover there is much conflict of opinion upon the relative values of the different monovalent anti-venom sera that are available. The principal poisonous substances in snake poison are hæmolytic, hæmorrhagic, leucolytic and neurotoxic, and there is some evidence that the proportions of

these toxic bodies may vary among different members of the same genus. In addition to the immediate use of a suitable anti-venom serum vigorous local treatment should always be undertaken. A ligature should be applied above the bite when the site permits; the wound should be opened up and thoroughly syringed with a solution of chlorinated lime or dressed with powdered potassium permanganate, ether and ammonia being given by the mouth and strychnine subcutaneously. The serum, to be of any real value, must be injected almost immediately after the bite. Anti-venom serum loses its strength on keeping, especially in the tropics. Anti-scorpion serum is useless against viperine venom.

Dose.—At least 100 millilitres, and more if possible, by intravenous injection.

ANTI-ADDER SERUM.—The only poisonous snake indigenous to England is the adder, *Viperus berus*. The normal dose of anti-adder serum is 10 millilitres or more intravenously.

SERUM NORMALE

(Serum Normal.)

Normal Serum

Synonym—Normal Horse Serum.

Normal serum is blood, free from corpuscles and fibrin. It is obtained from the blood of horses which are known to be free from glanders and tuberculosis and are in good condition. The blood is withdrawn usually from the jugular vein, under strict aseptic precautions, and is allowed to clot. As soon as the serum separates it is collected and a small quantity of a preservative, such as cresol, 0·4 per cent., or phenol, 0·5 per cent., is added. The serum is tested to determine the absence of hæmolytic or toxic properties; it is examined bacteriologically for sterility and is afterwards passed through Berkefeld filters before filling into sterile containers which are sealed so as to exclude bacteria. Normal serum contains serum-globulins, serum-albumins and fibrin ferment, together with the natural chemical substances of the blood serum.

Normal serum is a pale yellowish, slightly opalescent liquid, having no odour other than that of any antiseptic which may have been added. Normal serum should be **stored** below 15°, but should not be frozen. The label on the **container** states the date beyond which the serum must not be used and the nature and amount of preservative added.

Standard.—Normal serum complies with the tests for sterility and freedom from abnormal toxicity prescribed in the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Normal serum is administered in the treatment of hæmorrhage, in hæmophilia, in purpura, and in gastric and duodenal

ulcerations accompanied by hæmorrhage. The hæmostatic action of normal serum is attributed to the fibrin ferment present. In the treatment of hæmorrhage it is best administered by subcutaneous or intramuscular injection. In other conditions, such as anæmia, it may be given orally. In persons who are hypersensitive to the proteins of horse serum, the injection of normal serum may be followed by more or less pronounced symptoms of anaphylactic shock. These symptoms are also likely to occur in persons who have received serum treatment at some previous time. They may range from an urticarial skin eruption and œdema with joint pains to the more severe symptoms shown by rapid pulse, fall in temperature, dyspnœa, etc. These symptoms may appear from a few hours up to two weeks or so after the injection, but usually between the eighth and fourteenth days. In some cases, notably in asthmatic subjects, the symptoms may appear very rapidly and terminate fatally. Calcium chloride, calcium lactate, atropine and adrenaline may be used for the control of anaphylactic symptoms. Sensitivity to normal serum may be detected by an intradermal test and, if present, desensitisation by small doses (1 minim gradually increased), given at intervals of two hours, should be performed.

Dose.—10 to 20 millilitres (150 to 300 minims).

SEVUM

(Sev.)

Suet

Synonyms—Sevum Præparatum; Prepared Suet.

Suet is the internal fat of the abdomen of the sheep. It is prepared by cutting the fresh omentum into pieces, crushing the pieces so as to break the membranous vesicles in which the fat is enclosed, then melting and straining, the fat being stirred continuously while cooling to prevent the separation of constituents of high melting-point in a granular form. It occurs as a firm, white, almost odourless, fat, unctuous to the touch and having a bland taste. On prolonged exposure to the air, suet becomes rancid and then must not be used. Suet contains the glycerides of stearic and palmitic acids, about 70 to 80 per cent., together with about 20 to 30 per cent. of the glyceride of oleic acid. Tallow is the internal fat of various ruminant animals, particularly the ox and sheep. When pure it is white and almost odourless but usually it is yellowish and has a disagreeable odour. Tallow contains a number of mixed glycerides and is used in the manufacture of soap and candles.

Soluble in boiling alcohol (90 per cent.) (1 in 45) and ether (about 1 in 60); insoluble in water and cold alcohol (90 per cent.).

Standard, B.P.—Suet has a melting-point of 45° to 50°. Refractive index at 60°, 1.449 to 1.451. Acid value, not more than 2.0. Saponification value, 192 to 195. Iodine value, 33 to 46.

Uses.—Suet is used in the preparation of mercury ointment and as a solvent for phosphorus and salicylic acid. In India, suet should be used instead of lard in making the official preparations.

Preparations

Sevum Benzoinatum, B.P.C.—(Sev. Benz.)—Benzoinated Suet. Suet containing the fat soluble matter of 3 per cent. of benzoin.

This preparation was included in the British Pharmacopœia, 1914, under the name of Sevum Benzoatum.

Sevum Phosphoratum, B.P.C.—(Sev. Phosphor.)—Phosphorated Suet. Phosphorus, 10 per cent., in suet. Dose.—0·006 to 0·03 gramme ($\frac{1}{10}$ to $\frac{1}{2}$ grain).

SIMARUBA

(Simarub.)

Simaruba

Synonyms—Simarubæ Cortex; Simaruba Bark.

Simaruba consists of the dried root-bark of *Simaruba amara* Aubl. (Fam. Simarubaceæ), a tall tree indigenous to tropical America.

The bark occurs in long, very fibrous pieces, about 10 centimetres wide and 8 millimetres thick, more or less fissured and torn longitudinally; the outer surface is buff in colour, rough and deprived of its cork; the inner surface is yellowish-brown in colour, fibrous and longitudinally striated. The smoothed, transverse section shows numerous narrow medullary rays traversing the entire thickness of the bark. The freshly broken surface of the bark gives a characteristic yellowish-green fluorescence in ultra-violet light. The drug is without odour and has a bitter taste.

The diagnostic **microscopical** characters are the occasional pieces of thin-walled cork; the yellow, thick-walled, stone cells occurring singly and in ovoid groups in both cortex and phloem; the phloem fibres in groups of 5 to 20 and having moderately thickened, lignified walls; the prisms of calcium oxalate in many of the cells abutting upon the groups of stone cells and fibres; the presence of only a very few ovoid starch grains up to 16 microns in diameter.

Simaruba **contains** a crystalline bitter principle, a tasteless, crystalline substance, fixed oil, traces of a fluorescent body, and a yellow resin.

Substitutes, one of which is described as Maracaibo simaruba, are occasionally met with, and some of them are free from bitterness.

Action and Uses.—Simaruba has been used as a bitter, and as an astringent in chronic dysentery. It may be **administered** as a decoction (1 in 20).

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

SINAPIS NIGRA

(Sinap. Nig.)

Black Mustard

Black mustard consists of the seeds of *Brassica nigra* Koch. (Fam. Cruciferae), a plant largely cultivated in temperate climates.

The seeds are dark purplish-brown, nearly spherical, with a minutely pitted surface, and are about one millimetre in diameter. Internally, they are yellowish and oily, the section exhibiting two folded cotyledons embracing a small radicle. The taste is at first bitter, but rapidly becomes pungent. The dried seeds have little odour, but on triturating with water a pungent odour is developed.

The diagnostic **microscopical** characters are the large, thin-walled, epidermal cells containing mucilage; the single layer of small, polygonal, beaker-shaped, sclerenchymatous cells, varying in height as seen in sectional view from 3 to 10 microns and bearing a polygonal network (meshes 60 to 100 microns across) as seen in surface view; the dark brown pigment layer attached to the sclerenchymatous cells; the polygonal cells of the cotyledons and hypocotyl-radicle with thin cellulose walls, filled with fixed oil and small, rounded aleurone grains containing globoids but devoid of crystalloids.

Black mustard **contains** the glycoside, sinigrin, and the enzyme, myrosin. These interact in the presence of water to yield allyl isothiocyanate of which the drug yields from 0.6 to 1 per cent. It also contains proteins, mucilage and about 27 per cent. of fixed oil.

Uses.—Black mustard is used in the preparation of the volatile and fixed oils and, with white mustard, in the preparation of bath mustard, mustard bran and mustard flour.

SINAPIS ALBA.—White mustard is obtained from *Sinapis alba* Linn. (Fam. Cruciferae), cultivated in temperate countries. The seeds are yellowish in colour, nearly spherical in shape, and the surface is minutely pitted; they measure about 2 millimetres in diameter. The seeds have a pungent taste, but no odour, even when triturated with water. The microscopical characters resemble those of black mustard, excepting that the hypodermis is formed of collenchyma, and the sclerenchymatous beaker-cells are yellowish, of fairly uniform height and unaccompanied by a dark pigment layer. White mustard contains the crystalline glycoside, sinalbin, myrosin, fixed oil, mucilage and proteins. White mustard, with black mustard, is used for the expression of the fixed oil, and in the preparation of bath mustard, mustard bran and mustard flour.

BATH MUSTARD is similar in colour to mustard flour, but is in coarser powder; when examined microscopically, a slightly larger proportion of seed coats is found. Mustard baths for the feet are used for sleeplessness and in incipient colds, and a mustard sitz-bath is employed in amenorrhœa (1 tablespoonful to each gallon of water). Bath mustard should not be mixed with boiling water, or the pungent, volatile oil will be developed only to a limited extent owing to the destructive action of excessive heat on the myrosin.

MUSTARD BRAN is a coarse, brown powder with no distinct odour even when triturated with water; it has a slightly bitter but not pungent taste. It consists usually of the seed coats of black mustard.

MUSTARD FLOUR consists of the powdered seeds of black and white mustard, freed to a large extent from the seed coats. It is a yellowish-green, oily powder,

with a somewhat bitter and pungent taste and faintly oily odour, which becomes pungent when the powder is triturated with water. Cereal and scitamineous starches should be absent, and the powder should give no reaction for the colouring matter of turmeric. Mustard flour increases the flow of saliva and gastric juice. It is used as a condiment, and as an emetic in cases of poisoning (1 tablespoonful mixed in a tumblerful of hot water). It causes redness and a feeling of warmth when applied to the skin or mucous membrane; if the action be prolonged, vesication is produced. It is employed externally as a counter-irritant either in the form of poultice or as mustard paper (*Charta Sinapis*). Mustard paper is used as a counter-irritant in lumbago, congestion of the lung, pneumonia, bronchitis, phthisis and wherever counter-irritation is indicated. Small pieces of suitable size and shape may be applied to the temple or behind the ear, and fixed in position by a strip of adhesive plaster. Mustard paper should be dipped in tepid water for about fifteen seconds before being applied. "Half-strength" mustard papers are prepared, or one or two layers of damped muslin may be placed next to the skin, if the full-strength papers cause too much pain and irritation.

SODII ACETAS

(Sod. Acet.)

Sodium Acetate

Sodium acetate, $\text{CH}_3\cdot\text{COONa}, 3\text{H}_2\text{O}$, may be prepared by neutralising acetic acid with sodium carbonate or hydroxide and crystallising the resulting solution. It occurs in the form of odourless, colourless, translucent, monoclinic prisms or as a white, granular, crystalline powder having a cooling, saline, slightly bitter taste. It is efflorescent in warm air. The aqueous solution has an alkaline reaction. On heating, the salt first liquefies, then becomes anhydrous at 123° ; at a higher temperature it is decomposed, giving off inflammable vapours having an empyreumatic odour and leaving a residue of sodium carbonate.

Soluble in water (1 in 1) and alcohol (1 in 30).

Standard.—Sodium acetate, determined by the method of the British Pharmacopœia for *Potassii Acetas*, contains not less than 99·5 per cent. and not more than the equivalent of 105 per cent. of $\text{C}_2\text{H}_3\text{O}_2\text{Na}, 3\text{H}_2\text{O}$; each millilitre of N/2 sulphuric acid is equivalent to 0·06803 gramme of $\text{C}_2\text{H}_3\text{O}_2\text{Na}, 3\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. 0·5 gramme complies with the limit test for chlorides. 0·5 gramme complies with the limit test for sulphates. It complies with the limit tests for alkalinity, and aluminium and calcium in *Potassii Acetas*.

Action and Uses.—Sodium acetate is given as a diuretic and is used in place of sodium bicarbonate as a rectal injection in the treatment of uræmia. It is excreted as carbonate in the urine, which it renders less acid.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

SODII AMINARSONAS

(Sod. Aminarson.)

Sodium Aminarsonate

Sodium aminarsonate, or sodium *p*-aminophenylarsonate, may be prepared by heating aniline with arsenic acid and converting the arsonic acid formed into its sodium salt. The product contains a variable proportion of water, depending on the method employed for crystallisation; it usually contains from 3 to 4 molecules of water, which is not lost by drying at 110°. It occurs as a white, crystalline, odourless powder, having a slightly saline taste. Solutions of the salt reduce potassium permanganate and gold chloride; ferrous sulphate solution gives an olive-green precipitate, bromine solution a white precipitate, and sodium hypobromite solution a bluish-red colour (distinction from other arsenical compounds).

Soluble in water (1 in 5) and alcohol (about 1 in 125).

Standard.—Sodium aminarsonate contains not less than 24 per cent. and not more than 25.6 per cent. of As.

Assay.—Heat 0.2 gramme, accurately weighed, with 5.5 millilitres of sulphuric acid and 1 millilitre of fuming nitric acid for 1 hour; cool slightly, add 15 drops of fuming nitric acid and heat for a further five minutes; add cautiously 1 gramme of ammonium sulphate and when nitrogen ceases to be evolved, cool and dilute with water to about 70 millilitres. Add 1 gramme of potassium iodide and concentrate the solution to about 40 millilitres by boiling, add just sufficient N/100 sodium thiosulphate to decolourise the solution, dilute to 100 to 120 millilitres, add 50 millilitres of 4N sodium carbonate, neutralise by the addition of a slight excess of sodium bicarbonate and titrate with N/10 iodine using starch mucilage as indicator; each millilitre of N/10 iodine is equivalent to 0.003747 gramme of As.

Action and Uses.—Sodium aminarsonate is the prototype of the organic arsenical compounds. The arsenic compounds are inactive in the pentavalent form, their therapeutic activity being dependent upon conversion to the trivalent form when injected into the body. Sodium aminarsonate, which is stated to have one-fortieth the toxicity of arsenic, has been employed for the treatment of trypanosomiasis, syphilis, malaria and pernicious anæmia. For sleeping sickness, a warm 20 per cent. w/v solution has been recommended to be injected hypodermically, at first in small daily doses, gradually increasing to 1 millilitre (15 minims). This strength may, however, cause inflammation at the site of injection and a 10 per cent. w/v solution is preferable. After a week's treatment, injections of 1 millilitre (15 minims) of a 1 per cent. w/v solution of mercuric chloride are given on four successive days in place of the arsenical injections. Sodium aminarsonate is also used in association with some aniline dyes that exert a specific action upon

trypanosomes, such as trypan blue and trypan red, but owing to its relatively feeble trypanocidal action, together with the risk of causing optic atrophy, it has now largely yielded place to tryparsone. In cases where the cerebrospinal fluid is involved, the drug is of no value. In the treatment of syphilis, large doses, up to 0.6 gramme (10 grains), of this salt have been given by intramuscular injection, but they are sometimes followed by toxic symptoms; several cases of optic atrophy following this intensive treatment have led to its practical abandonment. Sodium aminarsonate is used for chronic skin diseases, similarly to sodium cacodylate and disodium methylarsonate, small doses only being employed orally. Most of the sodium aminarsonate injected is rapidly excreted unchanged in the urine. Solutions for **injection** may be sterilised by tyndallisation or by filtration. It is **incompatible** with acids, alkalis and salts of mercury and other heavy metals.

Dose.—0.05 to 0.2 gramme ($\frac{1}{2}$ to 3 grains).

SODII ARSENAS ANHYDROSUS

(Sod. Arsen. Anhydros.)

Anhydrous Sodium Arsenate

Synonyms.—Sodium Arseniate; Disodium Hydrogen Arsenate.

Anhydrous sodium arsenate may be obtained by heating the crystalline salt at a temperature of 150° until it ceases to lose moisture. It occurs in the form of an odourless, granular, amorphous, white powder. The aqueous solution has an alkaline reaction, due to partial hydrolysis. The dried salt is hygroscopic; it should be **stored** in well-closed containers.

Soluble in water (1 in 6); slightly soluble in alcohol (90 per cent.).

Standard.—Anhydrous sodium arsenate contains not less than 99.5 per cent. of Na_2HAsO_4 , calculated on the substance dried at 150°. Loss on drying at 150°, not more than 2 per cent. 1 gramme complies with the limit test for chlorides. 0.5 gramme complies with the limit test for sulphates.

Assay.—Dissolve about 0.25 gramme, accurately weighed, in 25 millilitres of water, add 3 grammes of potassium iodide and 25 millilitres of hydrochloric acid, and titrate the liberated iodine with N/10 sodium thiosulphate, using starch mucilage as indicator; each millilitre of N/10 sodium thiosulphate is equivalent to 0.009297 gramme of Na_2HAsO_4 .

Action and Uses.—Sodium arsenate has a mild arsenical action. It is employed in chronic skin diseases, in some forms of anæmia and in parasitic diseases of the blood, such as trypanosomiasis in man or animals. It is given in mixtures as Liquor Sodii Arsenatis, or in pills.

For hypodermic use, a solution containing 0.5 per cent. w/v of anhydrous sodium arsenate may be employed in doses of 1 millilitre (15 minims). Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.0015 to 0.006 gramme ($\frac{1}{40}$ to $\frac{1}{10}$ grain).

ACIDUM ARSENICUM.—Arsenic acid, $\text{H}_3\text{AsO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$, occurs in colourless, deliquescent crystals or as a granular powder. Melting-point, about 100° ; at 110° it becomes anhydrous; at a higher temperature it loses oxygen and water, and arsenic trioxide is formed and volatilised. It is very soluble in water, alcohol and glycerin. Arsenic acid is usually given as iron or sodium arsenate. It is rarely given in the free state, but may be administered in the form of an aqueous solution. The arsenic compounds produce the same effects as arsenous compounds, but they act more slowly and are less poisonous. **Dose.**—0.001 to 0.005 gramme ($\frac{1}{60}$ to $\frac{1}{12}$ grain).

PLUMBI ARSENAS.—Lead arsenate occurs as a white powder, insoluble in water but soluble in acid. It is used in the form of a paste, containing about 50 per cent. of lead arsenate, for horticultural purposes. It should be used with caution, and should not be applied to fruits and green vegetables on account of its highly poisonous properties, and should always be coloured before sale as a precautionary measure.

SODII ARSENAS.—Sodium arsenate, $\text{Na}_2\text{HAsO}_4 \cdot 7\text{H}_2\text{O}$, may be obtained by fusing together a mixture of arsenic trioxide, sodium nitrate and sodium carbonate until evolution of gas ceases; the fused mass is then treated with water and subsequently crystallised. This crystalline salt is the sodium arsenate of the International Agreement (*Natrii arsenas I.A.*), which contains the equivalent of 36.85 per cent. of arsenic pentoxide.

Preparation

Liquor Sodii Arsenatis, B.P.C.—(Liq. Sod. Arsen.)—Solution of Sodium Arsenate. It contains from 0.95 to 1.05 per cent. w/v of anhydrous sodium arsenate. 0.5 millilitre contains 0.005 gramme, and 8 minims contains about $\frac{1}{12}$ grain, of anhydrous sodium arsenate. **Dose.**—0.12 to 0.5 millilitre (2 to 8 minims).

This solution was included in the British Pharmacopœia, 1914.

SODII BENZOAS

(Sod. Benz.)

Sodium Benzoate

Sodium benzoate, $\text{C}_6\text{H}_5 \cdot \text{COONa}$, may be obtained by neutralising benzoic acid with sodium carbonate solution and crystallising. Two varieties are available, prepared respectively from natural and from synthetic benzoic acid. Sodium benzoate occurs as a white, amorphous, granular or crystalline powder, having an unpleasant, sweetish, saline taste. The compound prepared from synthetic benzoic acid is odourless while that from natural benzoic acid has a faint odour of benzoin. On the addition of a dilute mineral acid to the aqueous solution, a

precipitate of benzoic acid is produced. With ferric chloride solution a buff-coloured precipitate is obtained.

Soluble in water (1 in 2), and alcohol (90 per cent.) (1 in about 50).

Standard, B.P.—Sodium benzoate contains not less than 99 per cent. of $C_7H_5O_2Na$, calculated on the substance dried at 110° . Loss on drying at 110° , not more than 4 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. Melting-point of the separated benzoic acid, 121° to 122° . It complies also with limit tests for acidity or alkalinity, chlorinated compounds, chloride and sulphate.

Action and Uses.—Sodium benzoate has the action of benzoic acid, but is less irritating and is sometimes preferred on account of its ready solubility in water. It is sometimes employed as an expectorant, but is used principally as a urinary antiseptic, often in combination with hexamine, but is less useful than sodium acid phosphate for this purpose. It is converted by the kidneys into hippuric acid and is excreted as such. Sodium benzoate is best **administered** in solution. It is incompatible with acids and ferric salts. Solutions for **injection** may be sterilised by filtration.

Dose.—0.3 to 2 grammes (5 to 30 grains).

POTASSII BENZOAS.—Potassium benzoate, $C_6H_5\cdot COOK, 3H_2O$, occurs as small, efflorescent laminae or as a white, crystalline powder. It is soluble in water (1 in 1.5) and alcohol (1 in 18). Potassium benzoate has the properties of benzoic acid, and has been employed in cystitis, gout and rheumatism. It is best administered in solution. **Dose.**—0.3 to 2 grammes (5 to 30 grains).

SODII BICARBONAS

(Sod. Bicarb.)

Sodium Bicarbonate

Sodium bicarbonate, or sodium hydrogen carbonate, is usually obtained by passing carbon dioxide into brine saturated with ammonia, when sodium bicarbonate is precipitated and ammonium chloride remains in solution. It occurs as a white, odourless, minutely crystalline powder or in small, opaque, monoclinic crystals, having a saline taste and a feebly alkaline reaction. The aqueous solution slowly decomposes at ordinary temperatures with partial conversion into the normal carbonate; the decomposition is accelerated by agitation or by warming the solution. The dry substance is also decomposed when heated, and at 250° to 300° is converted into anhydrous sodium carbonate.

Soluble in water (1 in 11); insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium bicarbonate contains not less than 99 per cent. and not more than the equivalent of 101 per cent. of $NaHCO_3$. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It

complies also with a test for the absence of ammonium compounds, and with limit tests for aluminium, calcium and insoluble matter, alkalinity, chloride, sulphate and iron.

Action and Uses.—Sodium bicarbonate and similar alkaline compounds cause an initial reduction of secretion in the stomach, but this is followed by an increased secretion stimulated by the carbon dioxide liberated. It is used in the treatment of hyperchlorhydria with pain and distension, but the hydroxides of bismuth and magnesium are preferable. When taken for some time alkalis diminish the flow of pancreatic juice owing to a less acid chyme passing into the duodenum, with a consequent reduction in the amount of pancreatic secretion formed. After absorption, the alkali carbonates increase the alkalinity of the tissues and there is an increased excretion of urine, which is rendered less acid. The carbonates are largely employed in medicine with the object of retaining uric acid in solution in the urinary passages; they are of no value for dissolving uric acid already precipitated, but they form a means of preventing further precipitation. Alkalis are of the greatest value in all cases of acidosis, as in the recurrent vomiting of children, the toxæmia of pregnancy, phosphorus and arsenic poisoning and the acidosis of delayed chloroform poisoning. In such cases it is given in large doses with the addition of dextrose. Alkalis are also useful for their effect on the bronchial mucous membrane in bronchial catarrh and bronchitis, rendering the secretion less tenacious. Large doses are given in scarlet fever to prevent the onset of nephritis, and in acute nephritis quantities of sodium bicarbonate may be administered to keep the urine alkaline. Sodium bicarbonate is given twenty to thirty minutes after a meal to relieve the pain and eructation of hyperacidity. In order to inhibit excessive secretion in the stomach and to stimulate the appetite, it is given with bitters, such as gentian, thirty minutes before a meal. It is of great value in dyspepsia and in the bilious vomiting of children. For this purpose sodium bicarbonate in excess may be given with citric acid, in effervescence; for neutralisation, 20 parts of sodium bicarbonate require 16·7 parts of citric acid or 17·8 parts of tartaric acid.

Sodium bicarbonate is used to overcome excessive acidity of the urine and in the treatment of *Bacillus coli* infections of the urinary tract, and also in cases of jaundice and gall bladder infections. In the later stages of diabetes and in diabetic coma good results have followed the administration of large doses, but the benefit is only temporary. A 5 per cent. w/v solution in normal saline is administered intravenously in diabetic coma. In post-partum eclampsia, a 3 per cent. w/v solution is similarly administered. For its action in dissolving mucus, sodium bicarbonate is added to spray solutions and washes for the throat and nose. A weak solution (1 in 150) is applied to the skin to relieve the irritation of urticaria and eczema. A 2 per cent. w/v solution in water is used as an eye lotion. Sodium bicarbonate is best **administered** in dilute aqueous solution. Lozenges and tablets are prepared for use as an antacid in dyspepsia and flatulence. Solutions

for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. When the solution is sterilised by heating in an autoclave or by tyndallisation, the containers must be air-tight and the solution must almost completely fill the container. The containers should not be opened for one or two hours after the temperature of the solution has fallen to normal.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Balneum Effervescens, B.P.C.—(Baln. Efferv.)—Effervescent Bath. Each bath (30 gallons) contains 16 ounces of sodium bicarbonate and 8 ounces of sodium acid sulphate.

Balneum Effervescens cum Chlorido, B.P.C.—(Baln. Efferv. c. Chlorid.)—Effervescent Bath with Chloride. Each bath (30 gallons) contains 16 ounces of sodium bicarbonate, 8 ounces of sodium acid sulphate, 48 ounces of sodium chloride and 8 ounces of calcium chloride.

Liquor Alkalinus, B.P.C.—(Liq. Alk.)—Alkaline Solution. *Syn.*—Collunarium Alkalinum; Alkaline Nasal Wash. Sodium bicarbonate and borax, of each 1·5 per cent. w/v, with phenol and sucrose in distilled water.

Mistura Gentianæ Alkalina, B.P.C.—(Mist. Gent. Alk.)—Alkaline Gentian Mixture. *Syn.*—Mistura Gentianæ cum Soda. Each fluid ounce contains 15 grains of sodium bicarbonate and 5 grains of ammonium carbonate, with syrup of orange and compound infusion of gentian. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Sodii Bicarbonatis Aromatica, B.P.C.—(Mist. Sod. Bicarb. Aromat.)—Aromatic Sodium Bicarbonate Mixture. *Syn.*—Mistura Carminativa. Carminative Mixture. Each fluid ounce contains 10 grains of sodium bicarbonate, with aromatic spirit of ammonia, compound tincture of cardamom, glycerin and dill water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Nebula Alkalina Composita, B.P.C.—(Neb. Alk. Co.)—Compound Alkaline Spray. Sodium bicarbonate and borax, of each 1·5 per cent. w/v, and phenol, 0·75 per cent. w/v, in glycerin and distilled water.

Pulvis Boracis Compositus, B.P.C.—(Pulv. Borac. Co.)—Compound Borax Powder. *Syn.*—Pulvis Alkalinus Compositus, Compound Alkaline Powder. Sodium bicarbonate, sodium chloride and borax, equal parts.

Sodii Citro-Tartras Effervescens, B.P.C.—(Sod. Citro-Tart. Efferv.)—Effervescent Sodium Citro-Tartrate. An effervescent preparation containing sodium bicarbonate and citric and tartaric acids. **Dose.**—4 to 8 grammes (1 to 2 drachms).

Effervescent sodium citro-tartrate was included in the British Pharmacopæia, 1914.

Tabellæ Bismuthi et Sodii Bicarbonatis, B.P.C.—(Tab. Bism. et Sod. Bicarb.)—Bismuth and Sodium Bicarbonate Tablets. Each tablet contains 2 grains of bismuth carbonate and 3 grains of sodium bicarbonate. **Dose.**—1 to 3 tablets.

Tabellæ Sodii Bicarbonatis Compositæ, B.P.C.—(Tab. Sod. Bicarb. Co.)—Compound Tablets of Sodium Bicarbonate. *Syn.*—Soda Mint Tablets. Each tablet contains 5 grains of sodium bicarbonate, with ammonium bicarbonate, saccharin and $\frac{1}{4}$ minim of oil of peppermint. **Dose.**—1 to 4 tablets.

Tabellæ Zingiberis Compositæ, B.P.C.—(Tab. Zingib. Co.)—Compound Tablets of Ginger. *Syn.*—Ginger Mint Tablets. Each tablet contains 5 grains of sodium bicarbonate and $\frac{1}{4}$ grain of oleoresin of ginger, with ammonium bicarbonate, saccharin and $\frac{1}{4}$ minim of oil of peppermint. **Dose.**—1 or 2 tablets.

SODII BROMIDUM

(Sod. Brom.)

Sodium Bromide

Sodium bromide may be obtained by the methods described under potassium bromide using the corresponding sodium compounds in place of the potassium compounds. In order to obtain the anhydrous salt the solution is crystallised at a temperature above 50° . It occurs as odourless, transparent or opaque, colourless crystals or as a white, granular powder, somewhat deliquescent, and having a slightly bitter, saline taste. It does not appear moist until over 20 per cent. of water has been absorbed, owing to the formation of $\text{NaBr} \cdot 2\text{H}_2\text{O}$. It should be **stored** in well-closed containers.

Soluble in water (1 in 1.5) and alcohol (90 per cent.) (1 in 16).

Standard, B.P.—Sodium bromide contains not less than 99 per cent. of NaBr , calculated on the substance dried at 110° . Loss on drying at 110° , not more than 5 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for alkali, bromate, barium, chloride, sulphate and iron.

Action and Uses.—Sodium bromide has properties which closely resemble those of potassium bromide, but it is erroneously considered to be less depressing to the heart and less irritating to the stomach. It is employed in large doses in the treatment of the morphine and cocaine habits and in acute mania. In the treatment of epilepsy, sodium bromide has been recommended to be given with food in place of table salt so that the bromide may to some extent take the place of chloride in the tissues and exercise its specific effects on the nerve cells. The bromide treatment of epilepsy is, however, only palliative and some authorities consider it a matter for doubt whether prolonged intoxication with bromides is not a greater evil than an increased frequency of fits. A mixture of potassium, sodium and ammonium bromides is considered to have a better action than that obtained by one of these salts alone. To prevent the formation of the skin rash which often accompanies the bromide treatment, *Liquor Arsenicalis* is sometimes given concurrently. For cholecystographic purposes, 100 millilitres of a 10 per cent. w/v solution of sodium bromide is administered orally, and X-ray plates exposed at intervals from five to twelve hours afterwards. Sodium bromide is also used in pyelography to show the functional efficiency of the urinary tract; for this investigation, 7 to 10 millilitres of a 20 per cent. w/v solution of the bromide is injected by means of catheters into each ureter. Sodium bromide is usually **administered** in solution; if prescribed in powders, they should be wrapped in tin-foil and enclosed in a bottle. It is **incompatible** with salts of mercury and silver, oxidising substances and with spirit of nitrous ether.

Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0·3 to 2 grammes (5 to 30 grains).

Preparation

Mistura Bromidi Composita, B.P.C.—(Mist. Brom. Co.)—Compound Mixture of Bromides. Each fluid ounce contains 10 grains each of the bromides of ammonium, potassium and sodium, with tincture of nux vomica, solution of carmine, glycerin and chloroform water. **Dose.**—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

SODII CACODYLAS

(Sod. Cacodyl.)

Sodium Cacodylate

Synonym—Sodium Dimethylarsonate.

Sodium cacodylate, $\text{As}(\text{CH}_3)_2\text{O}_2\text{Na}, 3\text{H}_2\text{O}$, may be prepared by neutralising cacodylic acid with sodium carbonate, evaporating and crystallising. It occurs as white, odourless, prismatic crystals or as a white, granular powder, and is very deliquescent. It burns with a bluish flame, with the production of a garlic-like odour. It melts at about 60° and becomes anhydrous at 120° . A solution of the salt is alkaline to litmus and is not affected by silver nitrate solution, cobalt nitrate solution, or calcium chloride solution, but produces a white precipitate, turning yellow, with mercuric nitrate solution. A few drops of an aqueous solution (1 in 1000) allowed to stand in a stoppered tube with 2 millilitres of hypophosphorous acid develops the garlic-like odour of cacodyl within an hour. It should be **stored** in well-closed containers.

Soluble in water (2 in 1) and alcohol (1 in 1).

Standard.—Sodium cacodylate, determined by the method for Sodii Aminarsonas, contains not less than 72 per cent. and not more than 75 per cent. of $\text{C}_2\text{H}_6\text{O}_2\text{AsNa}$; each millilitre of N/10 iodine is equivalent to 0·007999 gramme of $\text{C}_2\text{H}_6\text{O}_2\text{AsNa}$. 1 gramme complies with the limit test for chlorides. 0·5 gramme complies with the limit test for sulphates. 2 grammes dissolved in 50 millilitres of water requires not more than 0·5 millilitre of N/10 sulphuric acid or more than 1·0 millilitre of N/10 sodium hydroxide to neutralise the solution, using phenolphthalein as indicator. 0·5 gramme dissolved in 10 millilitres of water is not rendered turbid, either in the cold or on heating, by calcium chloride solution (limit of disodium methylarsonate). 0·5 gramme in 10 millilitres of water is not rendered turbid within one hour on the addition of magnesium ammonio-sulphate solution (limit of arsenate and phosphate).

Action and Uses.—Sodium cacodylate owes any action it possesses to the small number of arsenic ions set free by the decomposition of the salt; its toxicity is quite disproportionate to the amount of arsenic in the molecule since it is absorbed and excreted mainly as cacodylate, which is itself an inert substance. It has been used in cases where arsenic is employed, especially in chronic skin affections, anæmias, malignant and tuberculous diseases, syphilis, etc. Sodium cacodylate in daily intravenous doses, commencing with 0.06 gramme (1 grain), is sometimes given in endocarditis. It may be **administered** in solution with aromatic elixir, or in pills prepared by triturating the salt with lactose and massing with glycerin of tragacanth. Given by the mouth in these forms, it communicates an alliaceous odour to the breath, a disadvantage which is reduced by the use of hypodermic injections. For the latter purpose a solution may be prepared containing 0.045 gramme ($\frac{3}{4}$ grain) in 1 millilitre (15 minims). More dilute solutions are employed for intravenous and rectal injection in phthisis. As much as 0.2 gramme (3 grains) is sometimes given for a dose. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. Sodium cacodylate is given intramuscularly in conjunction with sodium nucleate as a leucocyte stimulant in septicæmia.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

ACIDUM CACODYLICUM.—Cacodylic acid, or dimethylarsonic acid, $(\text{CH}_3)_2\text{AsO}\cdot\text{OH}$, occurs in colourless crystals which are hygroscopic and odourless when pure. Melting-point, about 200° . The addition of hypophosphorous acid produces the characteristic odour of cacodylic oxide. It is neutral to methyl orange and acid to phenolphthalein. It is soluble in water (2 in 1) and alcohol (1 in 3.5). Cacodylic acid is rarely administered in a free state; it is usually prescribed as iron or sodium cacodylate. The salts of cacodylic acid are very much less toxic than the corresponding arsenites and arsenates. **Dose.**—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

DISODII METHYLARSONAS.—Disodium methylarsonate, or sodium metharsinite, $\text{AsO}(\text{CH}_3)(\text{ONa})_2, 6\text{H}_2\text{O}$, is a white, crystalline powder. Its aqueous solution is alkaline to litmus and gives white precipitates with silver nitrate, lead acetate and mercuric nitrate solutions, a violet precipitate with cobalt nitrate, and a white precipitate on warming with calcium chloride solution. It is soluble in about 1 part of water and slightly soluble in alcohol. **Dose.**—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

FERRI CACODYLAS.—Iron cacodylate $[(\text{CH}_3)_2\text{AsO}]_2\text{Fe}$, occurs as a yellowish, amorphous powder, soluble in water (1 in 15), but almost insoluble in alcohol. Iron cacodylate has been recommended in chlorosis and other anæmias, and in such skin diseases as lichen, acne and lupus. It is administered in pill form, generally in doses of 0.016 to 0.03 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ grain) three times daily, and by hypodermic injection, daily doses of 0.05 gramme ($\frac{1}{2}$ grain) in distilled water being injected deeply into the gluteal region. Solutions for injection may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. They should be stored protected from light.

QUININÆ CACODYLAS.—Quinine cacodylate, $\text{C}_{20}\text{H}_{24}\text{O}_2\text{N}_2, (\text{CH}_3)_2\text{AsO}\cdot\text{OH}$, occurs in the form of acicular crystals or as a white powder. It is very soluble in water, and freely soluble in alcohol. Quinine cacodylate is given, with the cacodylates of iron and sodium, in pill form or in solution. **Dose.**—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

STRYCHNINÆ CACODYLAS.—Strychnine cacodylate, $\text{C}_{21}\text{H}_{22}\text{N}_2\text{O}_5, (\text{CH}_3)_2\text{AsO}\cdot\text{OH}$, occurs as a white, crystalline powder, slightly soluble in water, readily

soluble in chloroform. Strychnine cacodylate has chiefly the action of strychnine, and to a slight extent that of cacodylic acid. It is usually administered hypodermically or intramuscularly, often in combination with iron cacodylate and sodium glycerophosphate under the name of "ferruginous compound." Dose.—0·002 to 0·006 gramme ($\frac{1}{80}$ to $\frac{1}{16}$ grain).

SODII CARBONAS

(Sod. Carb.)

Sodium Carbonate

Sodium carbonate is obtained mainly by heating dry sodium bicarbonate and allowing an aqueous solution of the product to crystallise. It may also be prepared by passing carbon dioxide into a solution of sodium hydroxide obtained by electrolysis of brine. It occurs as transparent, colourless, odourless, rhombic crystals, with a strongly alkaline taste. The aqueous solution is alkaline to litmus. On exposure to air the crystals effloresce, the completely effloresced salt consisting of a mixture of the decahydrate and monohydrate equivalent to sodium carbonate containing about five molecules of water of crystallisation. When heated to about 50° the crystals fuse, and above 80° they lose the whole of their water of crystallisation, the loss in weight amounting to about 63 per cent. Monohydrated sodium carbonate, $\text{Na}_2\text{CO}_3, \text{H}_2\text{O}$, known in commerce as "crystal soda," is obtained by evaporating sodium carbonate solution at the boiling-point; it is not efflorescent and is largely used as a water softener and bath salt.

Soluble in water (1 in 2); insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium carbonate contains not less than 99 per cent. and not more than the equivalent of 102 per cent. of $\text{Na}_2\text{CO}_3, 10\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for aluminium, calcium and insoluble matter, chloride, sulphate, and iron.

Action and Uses.—Sodium carbonate is employed in the preparation of alkaline baths for use in scaly skin diseases, and an aqueous solution (0·5 per cent.) is used as a lotion, applied with a compress, to relieve irritation in eczema. The carbonate is also used to prepare "bath salts," the crystals often being coloured and perfumed for this purpose. To prevent the rusting of surgical instruments during sterilisation by boiling, 1 per cent. w/v of sodium carbonate may be added to the water in the steriliser.

Dose.—0·3 to 1 gramme (5 to 15 grains).

SODII SESQUICARBONAS.—Sodium sesquicarbonate, $\text{Na}_2\text{CO}_3, \text{NaHCO}_3, 2\text{H}_2\text{O}$, may be prepared from sodium bicarbonate. It occurs in the form of silky crystals or as a white powder and is sometimes used in the preparation of bath salts.

SODII CARBONAS EXSICCATUS

(Sod. Carb. Exsic.)

Exsiccated Sodium Carbonate*Synonym*—Anhydrous Sodium Carbonate.

Exsiccated sodium carbonate is nearly anhydrous sodium carbonate and may be obtained by heating any of the hydrated forms or by heating sodium bicarbonate. It occurs as a white, odourless powder, with a strongly alkaline taste. On exposure to the air it absorbs moisture and should be **stored** in well-closed containers,

Readily **soluble** in water.

Standard, B.P.—Exsiccated sodium carbonate contains not less than 99.5 per cent. of Na_2CO_3 , calculated on the substance dried at 110° . Loss on drying at 110° , not more than 2 per cent. Arsenic limit, 5 parts per million. Lead limit, 25 parts per million. It complies also with limit tests for aluminium, calcium and insoluble matter, chloride, sulphate and iron.

Action and Uses.—Exsiccated sodium carbonate is largely used as a bath powder and water softener. It is also the basis of bath salts for use in gout and rheumatism. Exsiccated sodium carbonate is employed in the preparation of pill masses such as *Pilula Ferri Carbonatis*.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

SODII CHAULMOOGRAS

(Sod. Chaulmoog.)

Sodium Chaulmoograte*Synonym*—Sodium Gynocardate.

Sodium chaulmoograte consists of a mixture of the sodium salts of chaulmoogric acid and other fatty acids obtained by the alkaline hydrolysis of chaulmoogra oil or of selected fractions of these acids. It occurs as a yellow or buff-coloured, granular solid or powder.

Soluble in water, giving a neutral or faintly alkaline solution.

Action and Uses.—Sodium chaulmoograte has an action similar to that of oil of chaulmoogra and is employed for the same purpose in the treatment of leprosy. The soluble sodium salts, or the ethyl esters, are now preferred to the expressed chaulmoogra and hydnocarpus oils. Injections are said to be better tolerated over a long period of treatment. Sodium chaulmoograte is **administered** in pills or capsules, or in 3 per cent. w/v solution for hypodermic, intramuscular, or intravenous use. Solutions for **injection** may be sterilised by tyndallisation at 60°

for one hour on three successive days. Weak solutions of sodium chaulmoograte may be sterilised by filtration.

Dose.—0·06 to 0·2 gramme (1 to 3 grains).

SODII CHLORAS

(Sod. Chloras)

Sodium Chlorate

Sodium chlorate may be prepared by the electrolysis of a hot solution of sodium chloride. It occurs in the form of colourless, odourless, translucent, tetrahedral crystals or as a white, crystalline powder, having a cooling, saline taste. The aqueous solution is neutral to litmus. It resembles potassium chlorate in all its properties and, on account of its liability to explosion under various conditions, the same precautions should be observed in dealing with it as with the potassium salt. On heating, it melts and then decomposes with the evolution of oxygen, leaving a residue of sodium chloride. The aqueous solution is coloured greenish-yellow on warming with hydrochloric acid and the odour of chlorine is evolved. It should be **stored** in well-closed containers.

Soluble in water (about 1 in 1), alcohol (1 in 100), boiling alcohol (1 in 40) and glycerin (1 in 5).

Standard.—Sodium chlorate, determined by the method of the British Pharmacopœia for Potassii Chloras, contains not less than 99 per cent. of NaClO_3 ; each millilitre of N/10 sodium thiosulphate is equivalent to 0·001774 gramme of NaClO_3 . Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. 0·5 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates.

Action and Uses.—Sodium chlorate is sometimes used for stomatitis, relaxed sore throats, etc., in the form of gargle, pastille and lozenge, in place of potassium chlorate which it closely resembles in its properties. It is also used as an ingredient of non-poisonous weed-killers.

Dose.—0·3 to 0·6 gramme (5 to 10 grains).

SODII CHLORIDUM

(Sod. Chlorid.)

Sodium Chloride

Sodium chloride is obtained by the purification of common salt. Deposits of salt occur in many parts of the world; the largest is found

in Galicia, but important beds are found in England and elsewhere. In cases where the salt deposit is under water, the brine is pumped to the surface and evaporated; in other cases the salt may be removed dry or, more usually, by pumping down water and subsequently withdrawing the brine. In all cases the brine obtained contains sulphates and chlorides of magnesium and calcium, the chlorides being responsible for the deliquescence of impure sodium chloride. These impurities may be removed by treatment with sodium carbonate or barium carbonate before evaporating the brine. Pure sodium chloride may be prepared by passing hydrogen chloride into strong brine. Sodium chloride occurs in colourless, odourless, transparent, cubical crystals or as a white, crystalline powder, having a saline taste.

Soluble in water (1 in 3), the solubility being nearly independent of the temperature, and glycerin (1 in 10); insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium chloride contains not less than 99.5 per cent. of NaCl, calculated on the substance dried at 130°. Loss on drying at 130°, not more than 1 per cent. Arsenic limit, 1 part per million. Lead limit, 5 parts per million. A 10 per cent. w/v aqueous solution is neutral to litmus. It complies also with limit tests for iodide and bromide, barium, calcium and magnesium, sulphate, and iron.

Action and Uses.—Sodium chloride and other soluble salts of a similar nature, when taken in large amounts, produce important physical effects. Osmosis is the principal physical change included under salt action, and osmotic processes play an important part in facilitating the movement of fluids and the diffusion of salts in the organism. The term isotonic has come to mean a solution having the same osmotic tension as that of human blood serum; higher molecular concentrations are spoken of as hypertonic and lower concentrations as hypotonic. An isotonic saline solution contains 0.9 per cent. w/v of sodium chloride. In the living body, however, osmotic processes, although important, are not always the deciding factor in the action of salts; thus the ions, K, Na, Li, Cl, Br, are absorbed rapidly from the intestines in any concentration, whilst the Ca ion is absorbed more slowly and the Mg and SO₄ ions hardly at all. A saline purgative is, therefore, a salt which is not capable of absorption or is at most only slowly absorbed, and which by osmosis attracts fluid from the intestinal cell-wall and renders the contents of the bowel more watery. From 5 to 12 grammes of sodium chloride is taken daily in the food and a corresponding amount is excreted in the urine. A decrease in the amount of chloride excreted occurs in certain cases of pneumonia and in continuous fevers. The most important action of the salt is that on the kidneys and is common to all salts which are absorbed. When salts reach the blood by absorption the flow of urine is increased; no matter how the salts are introduced into the blood, the effect must be to increase the liquid part of the blood; this hydræmic plethora causes dilatation of the renal vessels, a greater rate of blood flow and an increased secretion of urine. Sodium chloride will, however, according to its concentration, influence the passage of fluids into or out of the cells and may, therefore, be

employed as a purgative or laxative. If the quantity is large and highly concentrated, this withdrawal of water may irritate the cells of the mucous membrane and set up reflex vomiting.

Sodium chloride may be, and sometimes is, used as an emetic. As *Liquor Sodii Chloridi Physiologicus*, it is employed in large quantities for subcutaneous, intravenous, or rectal injection when the body has lost much fluid, as in hæmorrhage, acute diarrhœa, etc., also to prevent shock during prolonged operations, the injection being given at a temperature of about 40°. It is similarly employed in uræmia, diabetic coma, pneumonia and other intoxications to promote excretion of poisonous substances, and it is a suitable vehicle for hypodermic injections of alkaloids, etc. A 20 per cent. w/v solution has been used as a sclerosing agent for varicose veins. Solutions of sodium chloride for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Normal saline solution is employed in surgery to cleanse cavities and wounds. Hypertonic solutions or "packs" of sodium chloride are applied to carbuncles and other inflammatory processes to reduce local œdema. Saline solutions, 10 to 30 per cent. w/v, are also employed intravenously in acute intestinal obstruction after operation, post-concussional treatment and to reduce the œdema surrounding a cerebral tumour prior to operative procedures. The introduction of isotonic saline into the circulation after severe hæmorrhage or to combat shock is of little value, since in fifteen to twenty minutes most of the saline has been excreted during the profound diuresis which ensues. Hypertonic injections are a little better, the blood pressure returning to its former low level within an hour. More satisfactory results are obtained with *Injectio Sodii Chloridi et Acaciæ*, solutions of dextrose, 5 per cent. w/v, or by transfusing blood from a person of the same blood group or, failing that, from a "universal donor."

A salt-poor diet has been used in recent times as a treatment for renal disease with dropsy. In carefully selected cases great improvement has been obtained, patients who have been dropsical for years often losing all their œdema. A salt-poor diet is also used in various other conditions, particularly hyperpiesis. Sodium metabolism is intimately connected with the activity of the cortex of the suprarenal gland and sodium chloride in large doses, from 10 to 15 grammes daily, is sometimes effective in the treatment of Addison's disease and may replace or supplement treatment with extract of suprarenal cortex.

An ointment composed of equal parts of sodium chloride and soft paraffin is applied for ringworm. A solution of sodium chloride is used as a rectal injection for the expulsion of thread-worms. Sodium chloride baths are taken for the treatment of gout and rheumatism and for certain skin diseases.

Preparations

Injectio Sodii Chloridi et Acaciæ, B.P.—(*Inj. Sod. Chlorid. et Acac.*)—Injection of Sodium Chloride and Acacia. A sterile solution containing sodium chloride, 0.9 per cent. w/v. and acacia, 6 per cent. w/v, in freshly distilled water.

Liquor Dextrosi et Sodii Chloridi, B.P.C.—(Liq. Dextros. et Sod. Chlorid.)—Dextrose and Sodium Chloride Solution. *Syn.*—Glucose-saline Solution. A sterile aqueous solution containing 5 per cent. w/v of dextrose and 0.9 per cent. w/v of sodium chloride.

Liquor Ringer, B.P.C.—(Liq. Ringer)—Ringer's Solution. It contains sodium, potassium and calcium chlorides and sodium bicarbonate, and is isotonic with frogs' blood serum.

Liquor Ringer-Locke, B.P.C.—(Liq. Ringer-Locke)—Ringer-Locke Solution. It contains sodium, potassium and calcium chlorides, dextrose and sodium bicarbonate, and is isotonic with mammalian blood serum.

Liquor Ringer-Tyrode, B.P.C.—(Liq. Ringer-Tyrode)—Ringer-Tyrode Solution. It contains sodium, potassium, calcium and magnesium chlorides, dextrose, sodium acid phosphate and sodium bicarbonate, and is isotonic with mammalian blood serum.

Liquor Sodii Chloridi Physiologicus, B.P.—(Liq. Sod. Chlorid. Physiol.)—Physiological Solution of Sodium Chloride. *Syn.*—Physiological Saline Solution; Normal Saline Solution. A sterile aqueous solution containing sodium chloride, 0.9 per cent. w/v. When required for intravenous injection it should be prepared with sterilised water for intravenous injections, and should be used within twenty-four hours of its preparation.

This solution, prepared with 0.91 per cent. w/v of sodium chloride, was included in the British Pharmaceutical Codex, 1923, under the name of Liquor Sodii Chloridi.

Pulvis Boracis Compositus, B.P.C.—(Pulv. Borac. Co.)—Compound Borax Powder. *Syn.*—Pulvis Alkalinus Compositus; Compound Alkaline Powder. Sodium bicarbonate, sodium chloride and borax, equal parts.

Pulvis Sodii Chloridi Compositus, B.P.C.—(Pulv. Sod. Chlorid. Co.)—Compound Powder of Sodium Chloride. Sodium chloride, sodium bicarbonate, borax and sucrose, equal parts.

Solvellæ Boracis Compositæ, B.P.C.—(Solv. Borac. Co.)—Compound Solution—Tablets of Borax. Each tablet contains 5 grains of borax, $2\frac{1}{2}$ grains of sodium chloride, $\frac{1}{20}$ grain of thymol and $2\frac{1}{2}$ grains of sodium bicarbonate.

SODII CITRAS

(Sod. Cit.)

Sodium Citrate

Sodium citrate, $\text{COONa} \cdot \text{C}(\text{OH})(\text{CH}_2 \cdot \text{COONa})_2 \cdot 2\text{H}_2\text{O}$, may be obtained by neutralising citric acid with sodium carbonate in aqueous solution and crystallising from the hot solution. It occurs in the form of odourless, white, granular crystals or as a crystalline powder, having a saline taste. It is slightly deliquescent in moist air and is efflorescent in warm, dry air. On the addition of calcium chloride solution to a solution of sodium citrate, a clear liquid is produced in the cold which throws down a white, granular precipitate on boiling. A form of sodium citrate is also obtainable containing five and a half molecules of water of crystallisation. Sodium citrate should be **stored** in well-closed containers.

Soluble in water (1 in 2), boiling water (2.5 in 1); insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium citrate contains not less than 99 per cent. of $C_6H_5O_7Na_3 \cdot 2H_2O$. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with limit tests for alkalinity or acidity, tartrate, oxalate, chloride and sulphate.

Action and Uses.—Sodium citrate resembles potassium citrate in its properties and is similarly employed. It is used to raise the alkalinity of the blood in acidosis. It combines with the calcium salts of the blood, so as to delay the action of the fibrin ferment and lower the rate of clotting; added to milk its action is similar, so that the formation of large curds by the rennet of the stomach is prevented. It is employed for this action in the feeding of infants and invalids, milk being rendered more readily digestible by the addition of sodium citrate. It may be used in the proportion of 1 to 3 grains in each fluid ounce of milk, and for infant feeding a solution containing 2 grains of sodium citrate in 60 minims of water is commonly employed for each feed. Tablets of sodium citrate are frequently used for this purpose. The calcium salts are not removed from the milk; it seems probable that calcium citrate is formed, which salt, although slightly soluble, does not ionise, so that the calcium is not available for the purposes of the ferment. Although sodium citrate delays coagulation of blood *in vitro*, it is said to accelerate coagulation when given intravenously or intramuscularly; hence solution of sodium citrate in 5 per cent. w/v solution is sometimes given intravenously to prevent hæmorrhage at operations, etc. Intramuscularly, it is often given in a 30 per cent. w/v solution, 15 millilitres (225 minims) being injected into each buttock. To dilute blood and prevent its clotting a 2 per cent. w/v solution is used. For blood transfusion purposes 40 millilitres of a 3·8 per cent. solution should be added to the flask in which the blood is to be collected. This amount is adequate to prevent the clotting of 650 millilitres of blood. A solution of the same strength is usually employed for washing out the syringes and apparatus beforehand. Solution of sodium chloride with sodium citrate (1 part of each in 50) is applied to ulcers to promote the flow of lymph. Sodium citrate is **administered** in solution. A solution for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

SODII ET POTASSII TARTRAS

(Sod. et Pot. Tart.)

Sodium Potassium Tartrate

Synonyms—Potassii et Sodii Tartras; Rochelle Salt; Seignette's Salt; Soda Tartarata.

Sodium potassium tartrate, $COONa \cdot (CHOH)_2 \cdot COOK \cdot 4H_2O$, may

be prepared by neutralising potassium acid tartrate with sodium carbonate in the presence of water and crystallising. It occurs as colourless, odourless crystals or as a white, crystalline powder, having a saline, cooling taste.

Soluble in water (1 in 1.5); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium potassium tartrate contains not less than 99 per cent. and not more than the equivalent of 104 per cent. of $C_4H_4O_6NaK, 4H_2O$. Arsenic limit, 2 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for alkalinity or acidity, chloride, sulphate and iron.

Action and Uses.—Sodium potassium tartrate is a typical saline cathartic, causing a watery evacuation of the bowel without producing irritation. In small doses it is a diuretic and renders the urine less acid. It is employed in gout and rheumatism, to relieve hepatic congestion, and generally as a mild purgative. It is largely **administered** as Pulvis Effervescens Compositus (Seidlitz powder). Pulvis Effervescens Compositus Duplex (double-strength Seidlitz powder) contains twice as much sodium potassium tartrate as Pulvis Effervescens Compositus, and Pulvis Effervescens Compositus Fortis (extra-strong Seidlitz powder) contains one and a half times as much; the three powders contain the same quantities of sodium bicarbonate and tartaric acid. Sodium potassium tartrate is also used largely for the preparation of solutions of metallic tartrates such as Fehling's solution.

Dose.—8 to 16 grammes (2 to 4 drachms).

Preparations

Pulvis Effervescens Compositus, B.P.—(Pulv. Efferv. Co.)—Compound Effervescent Powder. *Syn.*—Pulvis Sodæ Tartaratæ Effervescens; Effervescent Tartarated Soda Powder; Seidlitz Powder. No. 1 powder contains 7.5 grammes (about 116 grains) of sodium potassium tartrate, with sodium bicarbonate. No. 2 powder contains tartaric acid. *Dose.*—Dissolve No. 1 powder in a tumbler of cold or warm water, and add No. 2 powder. The liquid should be taken while effervescing.

Pulvis Effervescens Compositus Duplex, B.P.C.—(Pulv. Efferv. Co. Dup.)—Double Compound Effervescent Powder. *Syn.*—Double-strength Seidlitz Powder. No. 1 powder contains 15 grammes (231½ grains) of sodium potassium tartrate, with sodium bicarbonate; No. 2 powder contains tartaric acid. It contains twice the amount of sodium potassium tartrate contained in compound effervescent powder. *Dose.*—Dissolve No. 1 powder in a tumbler of cold or warm water; then add No. 2 powder. The liquid should be taken while effervescing.

Pulvis Effervescens Compositus Fortis, B.P.C.—(Pulv. Efferv. Co. Fort.)—Strong Compound Effervescent Powder. *Syn.*—Extra-strong Seidlitz Powder. No. 1 powder contains 11.25 grammes (173½ grains) of sodium potassium tartrate, with sodium bicarbonate; No. 2 powder contains tartaric acid. It contains 50 per cent. more sodium potassium tartrate than is contained in compound effervescent powder. *Dose.*—Dissolve No. 1 powder in a tumbler of cold or warm water; then add No. 2 powder. The liquid should be taken while effervescing.

SODII FLUORIDUM

(Sod. Fluor.)

Sodium Fluoride

NaF = 42.00

Sodium fluoride is prepared technically by fusing sodium silicofluoride with sodium carbonate, lixiviating and evaporating the solution, or by boiling cryolite, $3\text{NaF}\cdot\text{AlF}_3$, with solution of sodium hydroxide of at least 1.380 specific gravity, when sodium fluoride separates as a crystalline powder. The pure salt may be prepared by neutralising a solution of hydrogen fluoride with a solution of sodium carbonate or sodium hydroxide in a platinum dish, evaporating the solution to dryness, exposing the residue to a strong heat for some time, and allowing to cool. Sodium fluoride occurs in the form of anhydrous, clear, lustrous cubes or as a white, crystalline powder, having a saline taste. The aqueous solution has an alkaline reaction and attacks glass; on heating, the salt decrepitates, and at a higher temperature melts without decomposition. When heated with concentrated sulphuric acid, vapours of hydrofluoric acid are given off which etch glass. It combines with borax to form sodium fluoborate, $6\text{NaF}\cdot\text{Na}_2\text{B}_2\text{O}_4$, with hydrogen fluoride forming the so-called acid fluoride, NaHF_2 , and with other fluorides forming double fluorides.

Soluble in water (1 in 25), scarcely more soluble in hot water; insoluble in alcohol.

Standard.—Sodium fluoride contains not less than 90 per cent. of NaF.

Assay.—Dissolve about 0.8 gramme, accurately weighed, in 50 millilitres of water and neutralise with carbonate-free alkali, using phenolphthalein as indicator; add sufficient neutral sodium chloride so that some remains undissolved at the end of the operation and titrate with M/10 potassium aluminium sulphate, using methyl red as indicator, the whole being kept at 80° ; each millilitre of M/10 potassium aluminium sulphate is equivalent to 0.0126 gramme of NaF.

Action and Uses.—Sodium fluoride has been given internally and by hypodermic injection in phthisis and in toxic goitre; it should be **administered** in mixture form in very dilute solution. In the treatment of toxic goitre 60 minims of a 2 per cent. w/v solution may be given three times a day with potassium iodide. Hypodermically it may be used as a solution (1 in 200), at which strength it has no caustic action. Sodium fluoride is used technically to prevent lactic and butyric fermentation in the manufacture of alcohol, 10 to 15 grammes being added to 100 litres of mash. It is said to arrest vital fermentations (due to development of living organisms) in the proportion of 1 per cent., but to have no disturbing action on chemical fermentations such as diastasic action. A 0.5 per cent. solution destroys most bacteria. Since it does not coagulate albumin, bacteria are not protected from its action by a coating of albumin. In very fine powder it is dusted on birds

to destroy vermin and is said to be fatal to cockroaches when placed in their runs.

Chronic poisoning may occur from the continued ingestion of small quantities of fluorides or from the inhalation of hydrofluoric acid, and is characterised by slowly progressive wasting, anæmia and brittleness of the bones. In cases of **poisoning** by large doses of sodium fluoride, the stomach should be washed out with lime water or weak solution of calcium chloride, and calcium chloride should be administered intravenously.

Dose.—0.005 to 0.03 gramme ($\frac{1}{12}$ to $\frac{1}{2}$ grain).

AMMONII FLUORIDUM.—Ammonium fluoride, NH_4F , occurs in colourless, deliquescent crystals or in crystalline masses, with a pungent, saline taste. It is fusible, and more volatile than ammonium chloride. It attacks glass with the formation of ammonia and ammonium silicofluoride and should therefore be stored in gutta percha vessels or in glass bottles coated internally with paraffin wax. It is soluble in water, the solution losing ammonia on evaporation. Ammonium fluoride has been suggested for use in the treatment of phthisis, enlargement of the spleen, and goitre. It should be administered in very dilute aqueous solution. **Dose.**—0.005 to 0.03 gramme ($\frac{1}{12}$ to $\frac{1}{2}$ grain).

POTASSII FLUORIDUM.—Potassium fluoride, KF , occurs in colourless, cubical or prismatic crystals or as a crystalline powder, having a sharp, saline taste. It is deliquescent, and attacks glass and porcelain from which it dissolves the silica. It is very soluble in water, the solution having an alkaline reaction. Potassium fluoride is seldom employed in medicine.

SODII FORMAS

(Sod. Form.)

Sodium Formate

Sodium formate, $\text{H}\cdot\text{COONa}, \text{H}_2\text{O}$, may be prepared by neutralising formic acid with sodium carbonate or bicarbonate, evaporating and crystallising. It occurs as a white, crystalline powder, deliquescent in moist air, and having a bitter, saline taste. On heating, the salt melts in its water of crystallisation, afterwards solidifying to a pearly, anhydrous mass. The anhydrous salt melts at about 254° ; it yields no acid distillate when strongly heated, but is decomposed into hydrogen and sodium oxalate. With sulphuric acid it evolves carbon monoxide. Its aqueous solution on boiling readily reduces many metallic salts and yields a red colour with ferric chloride solution.

Soluble in water (1 in 2) and glycerin.

Standard.—Sodium formate, determined by the method for Calcii Formas, contains not less than 96 per cent. of $\text{CHO}_2\text{Na}, \text{H}_2\text{O}$; each millilitre of $\text{N}/10$ potassium permanganate is equivalent to 0.004301 gramme of $\text{CHO}_2\text{Na}, \text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million.

Action and Uses.—Sodium formate exerts a marked diuretic action and is used, often in association with potassium or iron salts, for its supposed tonic effect on unstriated muscle as a general tonic in debility, in convalescence from acute disease, and in cardiac weakness. It has also been used in lumbago and rheumatism. It may be administered in mixture form or as Elixir Formatum Compositum, and is often combined with hypophosphites or glycerophosphates. It is sometimes given hypodermically in doses of 0·3 gramme (5 grains) in 2 millilitres (30 minims). Solutions for injection may be sterilised by heating at 100° for thirty minutes, by tyndallisation, or by filtration.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

Preparation

Elixir Formatum Compositum, B.P.C.—(Elix. Form. Co.)—Compound Elixir of Formates. *Syn.*—Elixir Formatum cum Strychnina; Elixir of Formates with Strychnine. Each fluid drachm contains about 3 grains each of sodium formate and potassium formate, and 1½ minims of solution of strychnine hydrochloride, with simple elixir. **Dose.**—4 to 8 millilitres (1 to 2 fluid drachms).

SODII GLYCEROPHOSPHAS

(Sod. Glycerophosph.)

Sodium Glycerophosphate

Synonym—Sodium Glycerylphosphate.

Sodium glycerophosphate is the sodium salt of β -glycerophosphoric acid and may be prepared by heating sodium acid phosphate with two molecular proportions of glycerin and hydrolysing the resulting diglyceryl ester with sodium hydroxide. It occurs as large, colourless, crystalline masses or as a white, crystalline powder. Sodium β -glycerophosphate may be distinguished from the α -salt by the fact that it does not reduce cold aqueous periodic acid.

Soluble in water (1 in 4).

Standard.—Sodium glycerophosphate contains not less than 98 per cent. and not more than the equivalent of 102 per cent. of $\text{C}_3\text{H}_7\text{O}_6\text{PNa}_2, 5\frac{1}{2}\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. Limit of free alkali (calculated as Na_2CO_3), 0·5 per cent. Limit of free phosphate (calculated as P_2O_5), 0·5 per cent.

Assay.—Dissolve 2·5 grammes in water and neutralise with N/1 hydrochloric acid, using thymol blue as indicator; the volume of acid required represents the free alkali present; each millilitre of N/1 hydrochloric acid is equivalent to 0·053 gramme of Na_2CO_3 . To the neutralised solution add 40 millilitres of 30 per cent. calcium chloride solution (neutral to thymol blue), boil for five minutes, cool and titrate with N/1 sodium hydroxide; the volume required represents the free phosphate

present; each millilitre of N/1 sodium hydroxide is equivalent to 0.071 gramme of P_2O_5 . Repeat the titration of 2.5 grammes with N/1 hydrochloric acid using bromocresol green as indicator, subtract from the volume used the sum of the volumes of N/1 hydrochloric acid required for the free alkali determination, and of N/1 sodium hydroxide for the phosphate determination, and calculate the remainder as sodium glycerophosphate; each millilitre of N/1 hydrochloric acid is equivalent to 0.3152 gramme of $C_3H_7O_6PNa_2 \cdot 5\frac{1}{2}H_2O$.

Action and Uses.—Sodium glycerophosphate in solid form is employed, usually in association with casein, in nervous debility, anæmia and general weakness. It is also used as a reagent for the determination of plasma phosphatases. Solutions for **injection** may be sterilised by heating at 100° for thirty minutes, by tyndallisation, or by filtration.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

SODII GLYCEROPHOSPHAS LIQUIDUS

(Sod. Glycerophosph. Liq.)

Solution of Sodium Glycerophosphate

Solution of sodium glycerophosphate is an aqueous solution containing about 50 per cent. w/w of a mixture of the neutral sodium salts of α - and β -glycerophosphoric acids, and may be prepared by the interaction of sodium carbonate and glycerophosphoric acid. It occurs as a colourless or not more than faintly yellow, syrupy liquid. A solution containing 75 per cent. is also found in commerce; it occurs as a thick syrup, often partly crystallised.

Miscible in all proportions with water.

Standard.—Solution of sodium glycerophosphate contains not less than 48 per cent. and not more than 52 per cent. by weight of $C_3H_7O_6PNa_2 \cdot 5\frac{1}{2}H_2O$. Specific gravity, 1.28 to 1.32. Refractive index, 1.395 to 1.405. Arsenic limit, 2.5 parts per million. Lead limit, 10 parts per million. Mix 5 grammes in a stoppered cylinder with 20 millilitres of dehydrated alcohol, add 5 grammes of recently ignited calcium sulphate, shake until the supernatant liquid is practically clear, filter into a 100 millilitre beaker, wash the residue in the cylinder with a few millilitres of dehydrated alcohol, evaporate the filtrate and washings, dry the residue at 70° for one hour, and weigh; the residue weighs not more than 0.10 gramme (limit of free glycerin). Limit of free alkali (calculated as Na_2CO_3), 0.5 per cent. Limit of free phosphate (calculated as P_2O_5), 0.5 per cent.

Assay.—Dilute 5 grammes with a little water and neutralise with N/1 hydrochloric acid using thymol blue as indicator; the volume of acid required represents the free alkali present; each millilitre of N/1 hydrochloric acid is equivalent to 0.053 gramme of Na_2CO_3 . To the

neutralised solution add 40 millilitres of 30 per cent. calcium chloride solution (neutral to thymol blue), boil for five minutes, cool, and titrate with N/1 sodium hydroxide; the volume required represents the free phosphate present; each millilitre of N/1 sodium hydroxide is equivalent to 0.071 gramme of P_2O_5 . Repeat the titration of 5 grammes with N/1 hydrochloric acid, using bromocresol green as indicator; subtract from the volume used the sum of the volumes of N/1 hydrochloric acid required for the free alkali determination, and of N/1 sodium hydroxide for the phosphate determination, and calculate the remainder as sodium glycerophosphate; each millilitre of N/1 hydrochloric acid is equivalent to 0.3152 gramme of $C_3H_7O_6PNa_2 \cdot 5\frac{1}{2}H_2O$.

Action and Uses.—Solution of sodium glycerophosphate resembles in its action the other glycerophosphates (see Acidum Glycerophosphoricum). It is given with other glycerophosphates in the form of Glycerinum Glycerophosphatum, Syrupus Glycerophosphatum Compositus, or other compound syrups.

Dose.—0.6 to 2 grammes (10 to 30 grains).

SODII HYDROXIDUM

(Sod. Hydrox.)

Sodium Hydroxide

$NaOH = 40.00$

Sodium hydroxide is usually obtained by the electrolysis of an aqueous solution of sodium chloride or by electrolysis of the fused salt. It occurs in scales or pellets, and in sticks or fused masses which are dry, hard and brittle, and break with a crystalline fracture. It is powerfully alkaline and corrosive, and rapidly destroys organic tissues. Exposed to the air, it rapidly absorbs moisture and liquefies, but subsequently becomes solid again and effloresces in consequence of the absorption of carbon dioxide with formation of sodium carbonate. When heated to about 525° , sodium hydroxide melts to a clear, viscid liquid, and at a bright red heat it slowly volatilises unchanged. The variety described as "purified by alcohol" was prepared by solution in alcohol, filtration to remove the less soluble carbonate and other salts and evaporation to dryness; an equally pure product is now obtained by the electrolytic processes of manufacture. A solution of sodium hydroxide free from carbonate may be obtained by dissolving the hydroxide in an equal weight of water; sodium carbonate is insoluble in the concentrated solution and may be separated by decantation or by filtration through asbestos. A concentrated aqueous solution cooled below -10° deposits thick, tabular crystals of the hydrate, $NaOH \cdot 7H_2O$, which melt above 6° . Sodium hydroxide should be **stored** in well-closed containers.

Soluble in water (1 in 1) and alcohol (90 per cent.).

Standard, B.P.—Sodium hydroxide contains not less than 95 per

cent. of total alkali, calculated as NaOH. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for carbonate, and for aluminium, iron and matter insoluble in hydrochloric acid.

Action and Uses.—Sodium hydroxide has properties which closely resemble those of potassium hydroxide, and may, in many cases, be similarly employed.

SODII PEROXIDUM.—Sodium peroxide, Na_2O_2 , is a white, amorphous, very hygroscopic powder. It is an extremely powerful oxidising agent, and is used chiefly in bleaching, liberating hydrogen peroxide when added to ice-cold, diluted mineral acids.

SODII HYPOPHOSPHIS

(Sod. Hypophosph.)

Sodium Hypophosphite

Sodium hypophosphite may be obtained by the interaction of sodium carbonate and calcium hypophosphite, with subsequent filtration and careful evaporation of the filtrate to dryness at a low temperature. It occurs as a white, deliquescent, odourless, granular powder, having a bitter, nauseous taste. The aqueous solution is neutral or slightly alkaline to litmus. On heating to about 200° , it is decomposed with evolution of spontaneously inflammable hydrogen phosphide. It is very liable to explode when mixed with nitrates, chlorates, or other oxidising agents. The aqueous solution acidified with hydrochloric acid and added drop by drop to mercuric chloride solution produces a white precipitate of mercurous chloride, which becomes grey on adding an excess; acidified with sulphuric acid and warmed with copper sulphate solution, it yields a red precipitate of cuprous hydride, which on boiling evolves hydrogen. If allowed to crystallise from water, or alcohol containing water, it has the formula $\text{NaH}_2\text{PO}_2 \cdot \text{H}_2\text{O}$.

Soluble in water (1 in 1), alcohol (90 per cent.) (1 in 30) and glycerin (1 in 2); insoluble in ether.

Standard.—Sodium hypophosphite, determined by the method for Calcii Hypophosphis, contains not less than 97 per cent. of NaH_2PO_2 , calculated on the substance dried at 110° ; each millilitre of N/10 iodine is equivalent to 0.004402 gramme of NaH_2PO_2 . Loss on drying at 110° , not more than 2 per cent. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. It complies with the limit tests for phosphate and barium in Calcii Hypophosphis.

Action and Uses.—Sodium hypophosphite resembles the hypophosphites of calcium and potassium in its action, and is usually prescribed therewith (see Acidum Hypophosphorosum).

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

SODII IODIDUM

(Sod. Iod.)

Sodium Iodide

NaI = 149.9

Sodium iodide may be prepared by methods analogous to those described for the preparation of potassium iodide, but the final recrystallisation must be conducted above 20° in order to avoid the deposition of the hydrated salt, $\text{NaI} \cdot 2\text{H}_2\text{O}$. It occurs as a white, odourless, granular, crystalline powder, with a saline, slightly bitter taste. It is deliquescent in moist air and is then liable to decomposition, becoming yellow in colour owing to liberation of iodine. The aqueous solution is slightly alkaline to litmus and gradually becomes coloured from liberation of free iodine on exposure to light and air. It melts at a dull red heat with loss of some iodine; at a higher temperature it slowly volatilises. On cooling, the fused substance solidifies to a pearly, crystalline mass. When sodium iodide is dissolved in water to form a strong solution, considerable heat is developed due to combination of the anhydrous salt with water; under similar conditions, potassium iodide produces a marked reduction in temperature. It should be **stored** in well-closed containers.

Soluble in water (about 2 in 1), alcohol (90 per cent.) (1 in 3) and glycerin (1 in 1).

Standard, B.P.—Sodium iodide contains not less than 99 per cent. of NaI, calculated on the substance dried at 110°. Loss on drying at 110°, not more than 5 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. It complies also with a test for absence of barium and with limit tests for alkali, iodate, cyanide and sulphate.

Action and Uses.—The properties of sodium iodide closely resemble those of potassium iodide; it is, however, considered to be less irritating to the stomach and less depressing (see Potassii Iodidum). Sodium iodide in the form of solution is also employed for pyelographic purposes. A solution of sodium iodide has been used by intravenous injection in the treatment of rheumatism and gonorrhœal epididymitis. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. A small proportion, usually about 1 in 200,000, is added to table salt for the prevention of goitre and the preparation is known as “iodised salt.”

Dose.—0.3 to 2 grammes (5 to 30 grains).

SODII MORRHUAS

(Sod. Morrh.)

Sodium Morrhuate

Sodium morrhuate consists of a mixture of sodium salts of acids

obtained by the alkaline hydrolysis of cod-liver oil. It occurs as a yellowish or buff-coloured solid. Sodium morrhuate is of variable composition and does not always form a clear, stable solution. It is also available in the form of solution and such solutions are usually more satisfactory in use. Care must be taken to prevent oxidation of the fatty acids. It should be **stored** in well-closed containers.

Soluble in water, giving a neutral or faintly alkaline solution.

Standard.—One gramme of sodium morrhuate dissolves completely to form a clear solution in 10 millilitres of warm water.

Action and Uses.—Sodium morrhuate is used largely as a sclerosing agent for varicose veins. A 5 per cent. solution is usually employed, 0·5 to 1 millilitre being injected into several parts of the vein being treated. If this fails to give the desired result after one month, injections of a 10 per cent. solution may be used; as much as 10 millilitres may be injected at one time. It is considered to have advantages over sodium or lithium salicylate or quinine and urethane for this purpose. After injections of sodium morrhuate, there is greater probability of recanalisation of the veins than after injections of sodium or lithium salicylate or quinine and urethane. In some patients sodium morrhuate injections give rise to an urticarial skin eruption. Sodium morrhuate is sometimes injected for hæmorrhoids. It has been employed in the treatment of lupus and leprosy, in doses of 0·5 to 2 millilitres (8 to 30 minims) of a 3 per cent. w/v solution injected subcutaneously or intramuscularly. Solutions of sodium morrhuate for **injection** may be sterilised by heating in an autoclave or by tyndallisation. Weak solutions of sodium morrhuate may be sterilised by filtration.

Preparation

Injectio Sodii Morrhuatæ, B.P.C.—(Inj. Sod Morrh.)—Injection of Sodium Morrhuate. 5 per cent. w/v. Dose.—0·5 to 5 millilitres (8 to 75 minims), by intravenous injection.

SODII NITRIS

(Sod. Nitris)

Sodium Nitrite

$\text{NaNO}_2 = 69\cdot01$

Sodium nitrite may be prepared by fusing sodium nitrate with metallic lead, added in small fragments. The fused salt is poured off from the separated lead oxide, allowed to cool, and recrystallised from water. It is also produced by the absorption of oxides of nitrogen in solution of sodium hydroxide. Sodium nitrite occurs in colourless or slightly yellow crystals or as a slightly yellow, granular powder, with a mild, saline taste; it readily deliquesces on exposure to air. It melts when

heated and at a red heat is decomposed with formation of sodium oxide and evolution of nitrogen, oxygen, and nitrogen peroxide. It should be stored in well-closed containers.

Soluble in water (1 in 1·5) and alcohol (90 per cent.) (1 in 50).

Standard, B.P.—Sodium nitrite contains not less than 95 per cent. of NaNO_2 . Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies also with limit tests for chloride and sulphate.

Action and Uses.—Sodium nitrite closely resembles glyceryl trinitrate in its action; the effect is produced rather more slowly than with the latter drug, but persists over a longer period. It is used especially in angina pectoris and asthma to ward off attacks and to relieve the symptoms during an attack; it is used also to lessen arterial tension in renal disease, and generally as a vasodilator. Spiritus Ætheris Nitrosi is used as a diaphoretic in incipient colds and as a mild diuretic, it is usually prescribed in mixtures with other diaphoretics such as Liquor Ammonii Acetatis Dilutus. When dispensed with potassium iodide, it should previously be neutralised by the addition of a small quantity of a bicarbonate. Sodium nitrite is mostly excreted as nitrate in the urine. It is **administered** in solution, and is sometimes given with sodium iodide, or with vasodilators such as diluted erythryl tetranitrate. It is **incompatible** with oxidising agents, phenazone, acetanilide, and caffeine citrate. In cases of **poisoning** by sodium nitrite, an emetic should be administered, the recumbent position maintained, and atropine given hypodermically.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

Preparations

Liquor Æthylis Nitritis, B.P.C.—(Liq. Æthyl. Nitrit.)—Solution of Ethyl Nitrite. A solution of ethyl nitrite, 2·5 to 3 per cent. w/w (equivalent to about 2 to 2·5 per cent. w/v) in a mixture of glycerin and dehydrated alcohol. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

This solution was included in the British Pharmacopœia, 1914, under the name of Liquor Ethyl Nitritis.

Nebula Hyoscinae Composita, B.P.C.—(Neb. Hyosc. Co.)—Compound Hyoscine Spray. Hyoscine hydrobromide, 0·057 per cent. w/v, cocaine hydrochloride, about 0·9 per cent. w/v, atropine sulphate, about 0·1 per cent. w/v, and sodium nitrite, 12·5 per cent. w/v, in glycerin and distilled water, coloured with solution of bordeaux B.

Spiritus Ætheris Nitrosi, B.P.—(Sp. Æther. Nitros.)—Spirit of Nitrous Ether. *Syn.*—Sweet Spirit of Nitre. An alcoholic solution containing not less than 1·25 per cent. and not more than 2·5 per cent. w/v of ethyl nitrite, together with acetaldehyde and other related substances. Alcohol content, 84 to 88 per cent. v/v of ethyl alcohol. Specific gravity, 0·838 to 0·842. It complies also with a limit test for acid. It should be stored in small, well-closed containers in a cool place and protected from light. Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Tabellæ Sodii Nitritis Compositæ, B.P.C.—(Tab. Sod. Nitrit. Co.)—Compound Tablets of Sodium Nitrite. Each tablet contains $\frac{1}{2}$ grain of sodium nitrite, $\frac{1}{4}$ grain of diluted erythryl tetranitrate and 1 grain of ammonium hippurate. Dose.—1 or 2 tablets.

SODII PERBORAS

(Sod. Perbor.)

Sodium Perborate

Sodium perborate may be prepared by treating a saturated solution of borax with an equivalent quantity of sodium hydroxide and at least twice the theoretical quantity of hydrogen peroxide, or by the electrolytic oxidation of sodium borate. It occurs in transparent, prismatic crystals or as a white powder, and is stable in the crystalline form. Aqueous solutions behave similarly to solutions of hydrogen peroxide, decolourising potassium permanganate and liberating iodine from potassium iodide, but they are more stable at temperatures below 60°. 1 millilitre of the saturated aqueous solution mixed with 1 millilitre of dilute sulphuric acid and 0.2 millilitre of potassium dichromate solution imparts a blue colour to 2 millilitres of ether when the latter is shaken with the mixture and allowed to separate.

Soluble in water (about 1 in 40, at 15°) with some decomposition. The solution is alkaline and contains hydrogen peroxide which slowly decomposes at ordinary temperatures. It is more soluble in a solution of boric, tartaric, or citric acid and in glycerin; its solubility is also increased by the presence of magnesium or ammonium sulphate.

Standard.—Sodium perborate contains not less than 96 per cent. and not more than the equivalent of 103 per cent. of $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$.

Assay.—Dissolve about 0.3 gramme, accurately weighed, in 50 millilitres of water; add 2 grammes of potassium iodide dissolved in 10 millilitres of water and 10 millilitres of dilute sulphuric acid and titrate with N/10 sodium thiosulphate, using starch mucilage as indicator; each millilitre of N/10 sodium thiosulphate is equivalent to 0.007694 gramme of $\text{NaBO}_3 \cdot 4\text{H}_2\text{O}$.

Action and Uses.—Sodium perborate is employed as an antiseptic and deodorant, its activity being due to liberation of oxygen by contact with catalysts or organic matter in the presence of moisture. As an application to wounds and ulcers it may be used in solution (2 per cent.), or as a dusting powder (2 to 10 per cent.), or the dressing may be dusted with the powdered substance. The solution may also be used as a vaginal douche. In Vincent's angina, sodium perborate is employed as a thick paste and allowed to remain in the mouth for five minutes before rinsing out. As an antiseptic and healing application a 1 per cent. sodium perborate ointment in soft paraffin is sometimes used. Oxygenated water may be prepared by mixing 170 grammes of sodium perborate and 60 grammes of citric acid in one litre of water, the strength of this solution being approximately equivalent to a 10 volume solution of hydrogen peroxide. Sodium perborate is used in conjunction with a suitable catalyst in some "oxygen bath salts" and is employed extensively in laundry work. As a dentifrice it may be diluted with 2 to 4 parts of precipitated chalk.

CALCI PERBORAS.—Calcium perborate may be prepared by double decomposition from solutions of calcium chloride and sodium perborate. Its composition is uncertain; the formula $\text{Ca}(\text{BO}_3)_2 \cdot 7\text{H}_2\text{O}$ has been assigned to it, but the salt rarely yields as much active oxygen as is indicated by this formula. It occurs as a bulky powder, but is not so stable as sodium perborate. Calcium perborate resembles sodium perborate in its properties. Mixed with twice its weight of precipitated chalk it has been used as a dentifrice.

MAGNESII PERBORAS.—Magnesium perborate may be prepared by the interaction of magnesium chloride and sodium perborate. Its composition is uncertain; the formula $\text{Mg}(\text{BO}_3)_2 \cdot 7\text{H}_2\text{O}$ has been assigned to it, but the commercial salt rarely yields as much active oxygen as is indicated by this formula. It occurs as a somewhat bulky powder which gradually decomposes with loss of oxygen. Magnesium perborate mixed with twice its weight of precipitated chalk has been used as a dentifrice.

SODII PHENOLSULPHONAS

(Sod. Phenolsulphon.)

Sodium Phenolsulphonate

Synonym—Sodium Sulphocarbolate.

Sodium phenolsulphonate, $\text{C}_6\text{H}_4(\text{OH})\text{SO}_2\text{ONa} \cdot 2\text{H}_2\text{O}$, may be prepared by digesting a mixture of phenol in excess of sulphuric acid at a temperature of 100° to 110° for about six hours, and converting the *p*-phenolsulphonic acid so obtained into the sodium salt. It occurs in colourless, odourless, transparent, rhombic prisms, slightly efflorescent in dry air, and having a saline and somewhat bitter taste. On heating to a little above 100° , the salt loses all its water of crystallisation (15·5 per cent.) and becomes white. At a higher temperature it chars, giving off inflammable vapours having an odour of phenol, and finally leaving a residue of sodium sulphate equivalent to about 30·6 per cent. of the original salt.

Soluble in water (1 in 6), boiling water (10 in 7), alcohol (1 in 150), boiling alcohol (1 in 10) and glycerin (1 in 5·5).

Standard.—Sodium phenolsulphonate contains not less than 99 per cent. and not more than the equivalent of 103 per cent. of $\text{C}_6\text{H}_5\text{O}_4\text{SNa}_2 \cdot 2\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit test for sulphates. 0·1 gramme dissolved in 10 millilitres of water is not rendered turbid by the addition of bromine solution (limit of free phenol).

Assay.—Dissolve about 0·15 gramme, accurately weighed, in 50 millilitres of distilled water in a glass-stoppered flask of about 500 millilitres capacity; add 50 millilitres of N/10 bromine and 5 millilitres of hydrochloric acid and allow to stand for fifteen minutes; add 2 grammes of potassium iodide dissolved in 5 millilitres of water and titrate the liberated iodine with N/10 sodium thiosulphate. Treat 50 millilitres of the N/10 bromine solution in the same way and titrate with

N/10 sodium thiosulphate; the difference between the two titrations represents the N/10 bromine absorbed by the sodium phenolsulphonate; each millilitre of N/10 bromine is equivalent to 0.005803 gramme of $C_6H_5O_4SN_2 \cdot 2H_2O$.

Action and Uses.—The phenolsulphonates resemble phenol in their action, but are very much less poisonous. Sodium phenolsulphonate diminishes putrefaction in the alimentary canal; it is absorbed and excreted in the urine unchanged. It is employed in cases of gastric flatulence and fermentative dyspepsia, and is best **administered** in solution in mixture form.

Dose.—0.3 to 1 gramme (5 to 15 grains).

SODII PHOSPHAS

(Sod. Phosph.)

Sodium Phosphate

Synonym—Di-sodium Hydrogen Phosphate.

Sodium phosphate may be obtained by the interaction of sodium carbonate and the solution of calcium acid phosphate produced on mixing bone-ash and sulphuric acid. Crystallisation is conducted below 35° in order to avoid deposition of the dihydrate, $Na_2HPO_4 \cdot 2H_2O$. It occurs as large, colourless, odourless, transparent, rhombic prisms, having a cooling, saline taste. The crystals are efflorescent in dry air, gradually losing 5 molecules of water of crystallisation. The aqueous solution is alkaline to bromocresol green. When heated to 40° the salt fuses, at 100° it loses its water of crystallisation, and at a dull red heat it is converted into the pyrophosphate, $Na_4P_2O_7$. When a solution of sodium phosphate is treated with an equimolecular proportion of sodium hydroxide and the solution evaporated, crystals of tribasic sodium phosphate, $Na_3PO_4 \cdot 12H_2O$, are obtained.

Soluble in water (1 in 7); almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium phosphate contains not less than 99 per cent. and not more than the equivalent of 105 per cent. of $Na_2HPO_4 \cdot 12H_2O$. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for calcium and magnesium, chloride and sulphate.

Action and Uses.—Sodium phosphate is a saline cathartic, resembling in its mode of action other salines of a similar nature. Owing to its comparative tastelessness it is used as an aperient for children, and also in some forms of children's diarrhoea. It may be given in milk or soup, or mixed with food. A small proportion of the salt is absorbed and exerts a mild diuretic action and is used as an "antilithic" in gout. Sodium phosphate is **administered** in solution in mixture form, or as

Sodii Phosphas Effervescens. The exsiccated salt is preferable to the crystalline salt for dispensing in bulk with other salts or in weighed powders.

Dose.—2 to 16 grammes ($\frac{1}{2}$ to 4 drachms).

SODII PYROPHOSPHAS.—Sodium pyrophosphate, $\text{Na}_4\text{P}_2\text{O}_7, 10\text{H}_2\text{O}$, may be prepared by exposing crystallised sodium phosphate to warm, dry air until it has effloresced and then heating the residue to dull redness. The product is dissolved in water and crystallised. It occurs in the form of colourless, odourless, transparent, monoclinic prisms or as a crystalline powder. On heating to 100° it loses its water of crystallisation. It is soluble in boiling water (1 in 1.1) and insoluble in alcohol. Sodium pyrophosphate is used only in the preparation of metallic pyrophosphates.

SODII PYROPHOSPHAS ACIDUS.—Sodium acid pyrophosphate is prepared by heating sodium acid phosphate, and occurs in commerce as the anhydrous compound, $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$, which is a white, amorphous powder. It is very soluble in water, the solution being neutral to methyl orange and acid to phenolphthalein. Sodium acid pyrophosphate is used in the manufacture of certain baking powders.

Preparation

Sodii Phosphas Effervescens, B.P.—(Sod. Phosph. Efferv.)—Effervescent Sodium Phosphate. It contains the equivalent of about 50 per cent. of sodium phosphate. It should be stored in well-closed containers. **Dose.**—4 to 16 grammes (1 to 4 drachms).

SODII PHOSPHAS ACIDUS

(Sod. Phosph. Acid.)

Sodium Acid Phosphate

Synonyms—Sodium Di-hydrogen Phosphate; Sodium Biphosphate.

Sodium acid phosphate may be prepared by combining sodium phosphate in hot solution with an equimolecular proportion of phosphoric acid. The resulting solution is concentrated, cooled and allowed to crystallise. It occurs as colourless, odourless crystals or as a crystalline powder, having an acid, saline taste. When heated at 100° it loses all its water of crystallisation. It melts at about 204° and decomposes, forming sodium acid pyrophosphate, $\text{Na}_2\text{H}_2\text{P}_2\text{O}_7$, and at about 250° it yields sodium metaphosphate, NaPO_3 . The aqueous solution is neutral to bromocresol green and acid to phenolphthalein.

Soluble in water (about 1 in 1), almost insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium acid phosphate contains not less than 98 per cent. of $\text{NaH}_2\text{PO}_4, 2\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for di-sodium phosphate, calcium and magnesium, chloride and sulphate.

Action and Uses.—Sodium acid phosphate is employed to render

the urine acid and is frequently combined with hexamine in the treatment of urinary infections and after operations on the bladder. Small repeated doses are preferred; they are less likely to set up diarrhoea and they produce a continuous excretion of the acid salt. It is **administered** in dilute, aqueous solution. For producing a general acidosis, ammonium chloride in 60 grain doses is more effective than sodium acid phosphate.

Dose.— 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm).

SODII PHOSPHAS EXSICCATUS

(Sod. Phosph. Exsic.)

Exsiccated Sodium Phosphate

Synonym—Anhydrous Sodium Phosphate.

Exsiccated sodium phosphate may be prepared by allowing sodium phosphate to effloresce for several days in warm air at a moderate temperature, further drying at 100° and maintaining it at that temperature until it ceases to lose weight. It occurs as a white powder which readily absorbs moisture. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 15).

Standard.—Exsiccated sodium phosphate, determined by the method of the British Pharmacopœia for Sodii Phosphas, contains not less than 99 per cent. of Na_2HPO_4 , calculated on the substance dried at 100° ; each millilitre of N/2 sulphuric acid is equivalent to 0.07101 gramme of Na_2HPO_4 . Loss on drying at 100° , not more than 2 per cent. Arsenic limit, 10 parts per million. Lead limit, 10 parts per million. It complies also with the limit tests for chlorides, sulphates and calcium and magnesium in Sodii Phosphas, using two-fifths the weight of substance for each test.

Action and Uses.—Exsiccated sodium phosphate has the same action as the crystalline salt. It is used for preparing effervescent granules or powders and in certain preparations where it would be disadvantageous to use the ordinary salt.

Dose.— 0.6 to 5 grammes (10 to 75 grains).

SODII SALICYLAS

(Sod. Salicyl.)

Sodium Salicylate

Sodium salicylate, or sodium *o*-hydroxybenzoate, $\text{C}_6\text{H}_4(\text{OH})\cdot\text{COONa}$, may be obtained by the interaction of salicylic acid and sodium

carbonate. It is sometimes described as "physiologically pure." A variety is also obtainable known as "natural" sodium salicylate and is prepared by neutralising "natural" salicylic acid with sodium hydroxide or carbonate. Sodium salicylate occurs in small, colourless crystals or crystalline flakes or as a white powder. The synthetic variety is odourless, but the "natural" compound has a faint, aromatic, characteristic odour. Sodium salicylate has an unpleasant, sweetish, saline taste. The saturated aqueous solution is liable to deposit crystals of a less soluble hydrated salt, $C_7H_5O_3Na \cdot 6H_2O$. An aqueous solution gives an intense violet colour on the addition of a trace of ferric chloride solution.

Soluble in water (1 in 1) and alcohol (90 per cent.) (about 1 in 6).

Standard, B.P.—Sodium salicylate contains not less than 99.5 per cent. of $C_7H_5O_3Na$, calculated on the substance dried at 110° . Loss on drying at 110° , not more than 1 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. Melting-point of the separated salicylic acid, 158° to 159° . It complies also with limit tests for free alkali or free acid, chloride and sulphate.

Action and Uses.—When taken internally sodium salicylate is absorbed very rapidly, circulating in the blood as such. It increases tissue break-down to a small extent and for twenty-four to forty-eight hours only, in spite of its administration being continued. The nitrogen (urea, uric acid, etc.), sulphates, phosphates, and chlorides in the urine are all increased, but the uric acid is increased out of proportion to the urea. It exerts a marked antipyretic action; about fifteen minutes after administration, dilatation of the skin vessels and some perspiration appear, followed by a fall in temperature. There is increased loss of heat so that the temperature falls in spite of the augmented metabolism. Salicylates have the power of cutting short an attack of acute rheumatism, their mode of action in this respect being unknown. They appear to produce a specific effect, since local application of volatile salicylates, such as methyl salicylate, or injection of soluble salicylates into the affected joints affords speedy relief. The salicylates are excreted as salicyluric acid (2-hydroxyhippuric acid), a compound of glycocholic acid with salicylic acid; it is a non-toxic substance and has none of the specific effects of the salicylates on acute rheumatism. Sodium salicylate is largely employed in acute rheumatism, and 1.25 grammes (20 grains) may be given every three hours until the temperature is reduced; the dose may be increased to 16 grammes (240 grains) daily, and in very severe cases 25 grammes (400 grains) daily have been given; large doses are given with twice as much sodium bicarbonate. It is more rarely employed as an antipyretic in pneumonia, typhoid fever and other pyrexias, and is given also in influenza, acute tonsillitis, chronic rheumatism, sciatica and all neuralgias of rheumatic origin. It exerts some antiseptic action in the stomach and arrests gastric fermentation; it is so rapidly absorbed, however, that it is useless as an intestinal antiseptic and a less soluble form, such as salol, is therefore preferred.

Sodium salicylate exerts a mild cholagogue action and is of value in hepatic and gall-bladder infections.

Some individuals exhibit an idiosyncrasy to salicylates, but everyone is liable to certain objectionable symptoms after large doses. These are headache, noises in the ears, confusion, indistinctness of vision, excessive sweating, skin eruptions, dyspnoea and a condition of collapse with subnormal temperature, weak pulse and unconsciousness. Gastro-intestinal disturbances are an indication for the temporary withholding of the drug. Salicylates must be used with care when there is renal inflammation.

Sodium salicylate is **administered** in solution in mixture form, when its taste may be disguised with tincture of orange or infusion of clove. It may be injected hypodermically at the seat of pain in doses of 0.06 to 0.1 gramme (1 to $1\frac{1}{2}$ grains). Solutions of 20 per cent. or 40 per cent. have been used as sclerosing injections for varicose veins. Great care is required in the use of sodium salicylate for this purpose since any solution which escapes into the surrounding tissues may give rise to sloughing. A solution of sodium salicylate is used for ionic medication in obstinate cases of fibrositis. When prescribed with alkali bicarbonates or with ammonium carbonate, the solution gradually acquires a reddish-brown colour; if the prescriber will authorise the addition, this change may be retarded by the addition of 1 grain of sodium pyrosulphite to an eight ounce mixture. Sodium salicylate forms a deep reddish-brown solution with spirit of nitrous ether, and a deep purple solution with iron salts; it is **incompatible** with acids and with solutions of some alkaloids. Mixtures containing quinine salts or cinchona preparations with sodium salicylate should contain no added acid; the alkaloidal salt in powder or the tincture or liquid extract of cinchona should be mixed with water containing one-eighth of its bulk of mucilage of acacia and the salicylate added in dilute solution. A solution of sodium salicylate for **injection** may be sterilised by tyndallisation or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.6 to 2 grammes (10 to 30 grains).

SODII SILICOFLUORIDUM

(Sod. Silicofluor.)

Sodium Silicofluoride

$\text{Na}_2\text{SiF}_6 = 188.1$

Synonyms—Sodium Fluosilicate; Sodium Silicifluoride.

Sodium silicofluoride may be prepared by neutralising an aqueous solution of hydrofluosilicic acid with a solution of sodium carbonate, or by adding hydrofluosilicic acid to a saturated solution of pure sodium chloride, washing the gelatinous precipitate of sodium silicofluoride thus obtained with distilled water, and thoroughly drying. It occurs in

the form of a fine, white, granular or crystalline powder, which is odourless, non-volatile, non-deliquescent, and gelatinous when moist. On cooling the boiling saturated solution, the salt is deposited in small, regular, hexagonal prisms. It melts at a red heat, giving off silicon tetrafluoride, SiF_4 . The aqueous solution is usually turbid and always acid in reaction. The corresponding acid does not attack glass.

Soluble in water (about 1 in 200) and boiling water (about 1 in 40); insoluble in alcohol.

Action and Uses.—Sodium silicofluoride in very dilute solution (1 in 500) has been used as an antiseptic, in which dilution it is non-caustic and non-poisonous. In concentrated solution it attacks surgical instruments and the enamel of porcelain.

SODII SULPHAS

(Sod. Sulph.)

Sodium Sulphate

Synonym—Glauber's Salt.

Sodium sulphate is obtained as a by-product in the manufacture of nitric and hydrochloric acids by heating the corresponding sodium salts with sulphuric acid. Large quantities are produced from the mineral deposits at Stassfurt by double decomposition between sodium chloride and mineral residues containing magnesium sulphate. It occurs in the form of colourless, odourless crystals, having a bitter, saline taste. It rapidly effloresces in dry air, forming the anhydrous salt. When heated to about 33° , the crystals liquefy owing to decomposition of the decahydrate into the anhydrous salt and water, which forms a saturated solution. The anhydrous salt fuses at a red heat without decomposition. Sodium sulphate readily forms a supersaturated solution when a saturated solution prepared above 33° is cooled.

Soluble in water (1 in 3 at 15° , or 3 in 1 at 33°), at higher temperatures the solubility decreases to 2 in 1 at 100° ; insoluble in alcohol (90 per cent.).

Standard, B.P.—Sodium sulphate contains not less than 99 per cent. and not more than the equivalent of 102 per cent. of $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$. Loss on drying at 100° , not less than 55 per cent. and not more than 56.35 per cent. Arsenic limit, 2 parts per million. Lead limit, 5 parts per million. It complies also with limit tests for acidity or alkalinity, iron and zinc, magnesium and chloride.

Action and Uses.—Sodium sulphate is not absorbed to any considerable extent and it therefore possesses the property, incidental to solutions of non-absorbable salts, of abstracting liquid from the tissues of the intestinal walls and acting as a saline cathartic. These saline

cathartics are best given in dilute solution except when it is desired, as in dropsical conditions, to abstract as much water from the tissues as possible, in which case concentrated solutions should be used. The presence of the salts in solution promotes this abstraction, and the large bulk of liquid in the intestine sets up reflex peristalsis without producing irritation. Sodium sulphate and the other saline cathartics are much employed in habitual constipation due to deficient peristalsis, the best results being obtained by taking the dose, well diluted, early in the morning on an empty stomach. Its action is rapid and is unaccompanied by pain or griping. It is used to lessen intestinal putrefaction by clearing out the contents of the bowels, and is also of service in some forms of obesity. Repeated doses of 4 grammes (60 grains) are given for bacillary dysentery. Sodium bicarbonate may usefully be given with sodium sulphate; the mixture closely resembles "Carlsbad salt" and is especially used in constipation associated with gouty or hepatic disorder. A small percentage of sulphate is absorbed and excites the kidney to increased secretion. Many aromatic substances are excreted in combination with sulphates, and where an excess of such bodies finds its way into the blood, either from excessive putrefaction in the alimentary canal or in poisoning by phenol and allied bodies, the administration of sulphates is required.

Sodium sulphate is **administered** in mixture form or as *Sodii Sulphas Effervescens*. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. The dried salt may be prescribed in powders, mixed with sodium bicarbonate and ginger, if so desired. The powdered crystalline salt forms a damp mass with sodium bicarbonate after being mixed for some hours. An effective freezing mixture is formed by adding to the crystals half their weight of strong hydrochloric acid, the temperature produced being the same as that of a mixture of ice and salt (-18°).

Dose.—2 to 16 grammes ($\frac{1}{2}$ to 4 drachms).

SODII SULPHAS ACIDUS.—Sodium acid sulphate, $\text{NaHSO}_4 \cdot \text{H}_2\text{O}$, or sodium bisulphate, occurs in crystals or fused masses. It is readily soluble in water and the solution has an acid reaction. Sodium acid sulphate is used with sodium bicarbonate for effervescing baths, and has been used for sterilising drinking water.

Preparations

Sal Carolinum Factitium, B.P.C.—(Sal Carol. Fact.)—Artificial Carlsbad Salt. It contains sodium sulphate, potassium sulphate, sodium carbonate and sodium chloride; $1\frac{1}{2}$ drachms is approximately equivalent to 1 pint of the natural water. **Dose.**—2 to 6 grammes ($\frac{1}{2}$ to $1\frac{1}{2}$ drachms).

Sal Carolinum Factitium Effervescens, B.P.C.—(Sal. Carol. Fact. Efferv.)—Effervescent Artificial Carlsbad Salt. *Syn.*—Effervescent Carlsbad Powder. An effervescing powder containing about 1 in 10 of exsiccated sodium sulphate and about 1 in $2\frac{1}{2}$ of sodium potassium tartrate, with sodium chloride, sodium bicarbonate, saccharin and tartaric acid. **Dose.**—4 to 8 grammes (1 to 2 drachms).

Sodii Sulphas Effervescens, B.P.—(Sod. Sulph. Efferv.)—Effervescent Sodium Sulphate. It contains the equivalent of about 50 per cent. of sodium sulphate. It should be stored in well-closed containers. **Dose.**—4 to 16 grammes (1 to 4 drachms).

SODII SULPHAS EXSICCATUS

(Sod. Sulph. Exsic.)

Exsiccated Sodium Sulphate

Synonyms—Anhydrous Sodium Sulphate; Exsiccated Glauber's Salt.

Exsiccated sodium sulphate may be prepared by drying sodium sulphate at 100° until it ceases to lose weight. It occurs as a white powder which readily absorbs moisture. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 8).

Standard.—Exsiccated sodium sulphate, determined by the method of the British Pharmacopœia for Sodii Sulphas, contains not less than 99 per cent. of Na_2SO_4 , calculated on the salt dried at 100°; each gramme of residue is equivalent to 0.6086 gramme of Na_2SO_4 . Loss on drying at 100°, not more than 5 per cent. Arsenic limit, 4 parts per million. Lead limit, 10 parts per million. It complies also with the limit tests for chlorides, iron and zinc, and magnesium in Sodii Sulphas, using half the weight of substance for each test.

Action and Uses.—Exsiccated sodium sulphate has the same action as the crystalline salt. It is used for preparing effervescing granules and powders, and for powders and certain other preparations for which the powdered crystals of sodium sulphate are not suitable.

Dose.—1 to 8 grammes ($\frac{1}{4}$ to 2 drachms).

SODII SULPHIS

(Sod. Sulphis)

Sodium Sulphite

Sodium sulphite may be prepared by the interaction of sulphurous acid and sodium carbonate. It occurs in colourless, odourless, transparent, monoclinic prisms, having a saline, sulphurous taste. It is efflorescent in air, becoming opaque and slowly oxidised to sulphate. Its aqueous solution is neutral or faintly alkaline to litmus and is more rapidly oxidised than the solid salt. On boiling a cold, saturated, aqueous solution, the anhydrous salt separates out as a crystalline powder which redissolves on cooling. On gently heating, the salt softens but does not fuse; above 100°, the crystals lose their water of crystallisation (practically 50 per cent.) without melting or losing their shape; at a red heat the salt fuses, yielding an orange-red mixture of sodium sulphide and sodium sulphate.

Soluble in water (1 in 2) and glycerin (1 in 25); insoluble in alcohol.

Standard.—Sodium sulphite contains not less than 94 per cent. of $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. 10 millilitres of an aqueous solution (1 in 10) is not rendered turbid on the addition of hydrochloric acid (limit of thiosulphate).

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 50 millilitres of N/10 iodine and titrate the excess of iodine with N/10 sodium thiosulphate, using starch mucilage as indicator; each millilitre of N/10 iodine is equivalent to 0.01261 gramme of $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$.

Action and Uses.—Sodium sulphite is an antiseptic, and in the presence of free acids sulphur dioxide is liberated (see *Acidum Sulphurosum*). Sulphites are also employed as food preservatives and they appear to be much less harmful than boric acid. A solution in glycerin and water (1 in 8) is used as a paint in aphthous conditions of the mouth and a 5 per cent. solution is used as a lotion in parasitic skin diseases. It is given internally in gastric fermentation due to yeasts and sarcinae and is best **administered** in solution in mixture form. It is **incompatible** with acids. Sodium sulphite is used largely as a reducing agent in the arts.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

POTASSII PYROSULPHIS.—Potassium pyrosulphite, potassium metabisulphite or potassium bisulphite, $\text{K}_2\text{S}_2\text{O}_5$, may be prepared by passing sulphur dioxide to saturation into a solution of caustic potash or potassium carbonate. It is used as a reducing agent in photography and, in small quantities, for preventing discolouration in certain ointments, especially those containing resorcinol.

SODII PYROSULPHIS.—Sodium pyrosulphite, sodium metabisulphite, or sodium bisulphite, $\text{Na}_2\text{S}_2\text{O}_5$, may be prepared by passing sulphur dioxide to saturation into a solution of caustic soda or sodium carbonate. As the solution cools, crystals are deposited. It occurs in the form of opaque, prismatic crystals or as a white, amorphous powder, having an unpleasant, sulphurous, saline taste. It is liable to deteriorate when kept under unfavourable conditions and should be stored in well-closed containers in a cool place. On exposure to air and moisture, it becomes slowly oxidised to sulphate. It dissolves sulphur, forming sodium thiosulphate and also the haloid salts of silver. When heated, it decrepitates and gives off sulphur dioxide and sulphur, leaving a residue of sodium sulphate. It is a powerful reducing agent owing to the facility with which it passes into sodium sulphate. It is readily soluble in water and in boiling water (about 1 in 2). Sodium pyrosulphite is used as a reducing agent, and as a reagent for the preparation of organic sulphite compounds. It is also used largely as a food preservative (see *Acidum Sulphurosum*).

SODII TAUROGLYCOCHOLAS

(Sod. Tauroglycochol.)

Sodium Tauroglycocholate

Synonym—Bile Salts.

Sodium tauroglycocholate consists chiefly of a mixture of sodium taurocholate, $\text{C}_{26}\text{H}_{44}\text{O}_7\text{NSNa}$, and sodium glycocholate, $\text{C}_{26}\text{H}_{42}\text{O}_6\text{NNa}$.

It may be prepared by extracting dried ox or pig bile with dehydrated alcohol, decolourising with charcoal and precipitating the salts from the solution by adding an excess of ether. It occurs as a yellowish-brown, hygroscopic powder, having a sweet but afterwards bitter taste, and an odour resembling that of fresh bile. The aqueous solution froths when shaken and possesses the power of dissolving fatty acids. The solution is precipitated by lead acetate, ferric chloride, or silver nitrate. On hydrolysis with alkali these salts are split up into cholic acid and taurine and glycerin respectively. On adding concentrated sulphuric acid drop by drop to an aqueous solution in which a small crystal of cane sugar has been dissolved or to which a trace of furfural has been added, a brownish-red colour is formed changing to violet and becoming blue on keeping. Sodium tauroglycocholate is often erroneously termed sodium "taurocholate" or sometimes "choleate." Sodium tauroglycocholate should be **stored** in a cool place protected from moisture, but preferably not in stoppered bottles.

Soluble in water (2 in 1) and alcohol; insoluble in ether.

Standard.—Sodium tauroglycocholate yields not less than 16 per cent. of sulphated ash.

Action and Uses.—Sodium tauroglycocholate is given in cases of supposed deficiency of biliary secretion to assist emulsification of fats and as a purgative. It is a true cholagogue, and is of service in some forms of intestinal dyspepsia since it assists pancreatic digestion. It is of value in facilitating the action of some purgatives and in forming emulsions. Sodium tauroglycocholate is best **administered** in capsules. It is a constituent of some bacteriological culture media; the sodium salts of taurocholic and glycocholic acids, while having some lytic action on pneumococci, have only a fraction of that possessed by desoxycholic acid and its salts, and therefore sodium tauroglycocholate is not suitable for use in the identification of pneumococci. A mixture containing 1 per cent. of sodium tauroglycocholate with 5 per cent. of oil of eucalyptus in water is used for the destruction of pediculi.

Dose.—0·12 to 0·4 gramme (2 to 6 grains).

SODII DESOXYCHOLAS.—Sodium desoxycholate, or sodium deoxycholate, $C_{24}H_{39}O_4Na$, may be prepared by hydrolysing sodium tauroglycocholate with alkali and crystallising the bile acids, separating on acidification, from glacial acetic acid. Desoxycholic acid separates in colourless crystals. Sodium desoxycholate occurs as a white powder, readily soluble in water. It is extremely irritating when inhaled.

SODII GLYCOCHOLAS.—Sodium glycocholate, $C_{26}H_{42}O_6NNa$, may be prepared from sodium tauroglycocholate by precipitating with lead acetate and decomposing the precipitate suspended in alcohol with hydrogen sulphide. Glycocholic acid is set free and may be converted into the sodium salt by neutralisation with sodium hydroxide.

SODII TAUROCHOLAS.—Sodium taurocholate, $C_{28}H_{44}O_7NSNa$, is obtained from the filtrate from the lead acetate precipitation of sodium tauroglycocholate and may be purified by precipitation with basic lead acetate. The free acid is liberated from its lead salt and neutralised with sodium hydroxide.

SODII THIOSULPHAS

(Sod. Thiosulph.)

Sodium Thiosulphate*Synonym*—Sodium Hyposulphite.

Sodium thiosulphate may be prepared by boiling a solution of sodium sulphite with powdered roll sulphur, filtering, and evaporating the solution to crystallisation, or, on the large scale, by exposing soda-waste to air, thereby converting the calcium sulphite contained in it into calcium thiosulphate, and decomposing the latter by means of sodium carbonate or sulphate, separating the insoluble lime salt formed and recovering the sodium thiosulphate from the solution by filtration, evaporation and crystallisation. Gas-lime treated in a similar way is also used for its manufacture. Sodium thiosulphate occurs in the form of colourless, odourless, transparent, monoclinic prisms, having a cooling and afterwards bitter, slightly alkaline and sulphurous taste. The crystals are somewhat damp to the touch; they are slightly deliquescent in moist air and efflorescent in dry air above 33°. On boiling, the aqueous solution is rapidly decomposed. When rapidly heated, sodium thiosulphate melts in its water of crystallisation at 50°, at 100° it loses all its water of crystallisation and at a red heat it is decomposed with liberation of sulphur, leaving a residue of sodium sulphide and sulphate. It also loses its water of crystallisation over sulphuric acid. On acidifying the aqueous solution, it is decomposed with the production of sulphurous acid and sulphur, the latter forming a white precipitate (distinction from sulphites).

Soluble in water (5 in 3); slightly soluble in oil of turpentine; insoluble in alcohol.

Standard.—Sodium thiosulphate contains not less than 99 per cent. of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. The 10 per cent. w/v aqueous solution is neutral or not more than faintly alkaline to litmus. 0.5 gramme dissolved in 10 millilitres of water produces no turbidity with ammonium oxalate solution (limit of calcium).

Assay.—Dissolve about 1 gramme, accurately weighed, in water and titrate with N/10 iodine, using starch mucilage as indicator; each millilitre of N/10 iodine is equivalent to 0.02482 gramme of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$.

Action and Uses.—Sodium thiosulphate has been recommended for internal use similar to that of sodium sulphite, but is rarely so employed. A solution in sterilised water, 0.3 to 0.9 gramme in 10 millilitres (5 to 14 grains in 150 minims), is administered by intravenous injection as an antidote in cases of over-dosage of arsphenamine compounds and salts of bismuth, mercury and gold. After extraveneous leakage of arsphenamine compounds the area should be infiltrated immediately

with a sterile solution of sodium thiosulphate. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration. Sodium thiosulphate is extensively used in photography on account of its property of forming double salts with silver. In fixing photographic prints it acts by dissolving the unaltered portion of the sensitive film, forming soluble double salts with the silver chloride, bromide, or iodide. A strong solution in water has been used in gas-masks to absorb chlorine, and as an "antichlor" it is used for removing the chlorine remaining after bleaching operations.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

MAGNESII THIOSULPHAS.—Magnesium thiosulphate, $\text{MgS}_2\text{O}_3 \cdot 6\text{H}_2\text{O}$, may be prepared by the interaction of barium thiosulphate and magnesium sulphate. It occurs as colourless, odourless crystals which effloresce in dry air. It is soluble in water (1 in 1.5), the solution being slightly alkaline to litmus, but insoluble in alcohol. Magnesium thiosulphate has been used in the treatment of asthma. It is administered by intramuscular injection in doses of 5 to 10 millilitres of a 10 per cent. solution at intervals of four days, and by the mouth in doses of 1 gramme (15 grains) three times a day.

SODII VALERIANAS

(Sod. Valer.)

Sodium Valerianate

Synonym—Sodium Valerate.

Sodium valerianate may be prepared by neutralising valerianic acid with a solution of sodium hydroxide, evaporating the solution to dryness, heating the saline residue carefully until it melts, and breaking up the cooled mass into small fragments. The salt is difficult to crystallise from water, but by evaporation of the neutral solution in dry air at 32° crystals may be obtained. It occurs in the form of white, hygroscopic masses, unctuous or soapy to the touch, having a neutral or slightly alkaline reaction, a weak odour of valerian when quite dry, more pronounced when moistened and warmed, and a sweetish taste with a somewhat bitter and pungent after-taste. When heated at 140°, it melts without decomposition to a colourless liquid and on cooling it solidifies with a crystalline structure; at a higher temperature it gives off pungent, acid vapours and inflammable gas, and on complete ignition it leaves a residue of sodium carbonate. When a concentrated solution is acidified, valerianic acid separates as an oily layer on the surface of the liquid. It should be **stored** in well-stoppered bottles.

Freely **soluble** in water and alcohol.

Standard.—Sodium valerianate, determined by the method of the British Pharmacopœia for Sodii Salicylas, contains not less than 85 per cent. of $\text{C}_6\text{H}_9\text{O}_2\text{Na}$; each millilitre of N/2 sulphuric acid is equivalent to

0.06203 gramme of $C_6H_5O_2Na$. Arsenic limit, 5 parts per million. Lead limit, 10 parts per million. 1 gramme complies with the limit test for sulphates. 1 gramme dissolved in water requires not more than 1 millilitre of N/10 sodium hydroxide for neutralisation to phenolphthalein (limit of free acid).

Action and Uses.—Sodium valerianate resembles other valerianates in its action and is used for its psychical effect in hysteria and other nervous disorders. In other respects its action is similar to that of sodium acetate. It is sometimes **administered** in pills with zinc and iron valerianates, or in solution in mixture form with ammonium valerianate or aromatic spirit of ammonia. It is **incompatible** with acids.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

SOJA

(Soya)

Soya

Synonyms—Sojæ Semina; Soy Beans; Soya Beans.

Soya consists of the seeds of *Glycine Soja* Sieb. and Zucc. (Fam. Leguminosæ), an annual plant cultivated in China, Japan, India, Manchuria, America and the Dutch East Indies.

The seeds are usually pale yellow in colour although brown or black varieties also occur. They are roundly ovoid in shape, measuring on the average 8 millimetres long, 7 millimetres wide and 6 millimetres thick. The hilum is 3 to 4 millimetres long and is found in the middle of one of the longer edges of the seed. The leathery and somewhat translucent seed coat surrounds two plano-convex cotyledons which enclose a small radicle and plumule. The seeds are without odour, and the taste is bland and oily.

The chief diagnostic **microscopical** characters are the palisade cells of the seed coat epidermis up to 50 microns high and 20 microns wide; the single row of thick-walled bearer cells varying in length from 40 to 120 microns and in width from 20 to 35 microns; the cells of the cotyledons filled with closely packed aleurone grains, 3 to 11 microns wide, and droplets of fixed oil; the occasional cells containing prismatic crystals of calcium oxalate about 25 microns long and 5 microns wide. Starch is absent.

Soya **contains** fixed oil (about 18 per cent.), proteins (about 40 per cent.), carbohydrates (about 22 per cent.), and the enzyme, urease. The proteins are remarkable on account of the large proportion soluble in water. The ash is about 5 per cent.

Uses.—Soya is used chiefly for the production of soya oil. It is sometimes used in the manufacture of food products, and soya cake is

used as a fertiliser and for cattle food. Soya is also used for the determination of urea.

UREASUM.—Urease is an enzyme, present in soya, which has the power of converting urea into ammonium carbonate. It is extracted by means of dilute alcohol or acetone, and a partly purified form is sometimes used instead of soya in the determination of urea in blood and urine.

SPARTEINÆ SULPHAS

(Spart. Sulph.)

Sparteine Sulphate

Sparteine sulphate is a salt of the dibasic alkaloid, sparteine, and may be prepared by neutralising the colourless alkaloid, 10 parts, with dilute sulphuric acid, about 40 parts of 10 per cent. solution, rapidly concentrating the solution, and allowing to crystallise in a warm place. Under varying conditions it crystallises with different proportions of water, and may also be obtained in the form of an anhydrous salt, but by recrystallisation from diluted alcohol the salt containing five molecules of water of crystallisation is obtained. It occurs in the form of colourless, odourless, rhombohedral crystals or as a white, crystalline powder, having a slightly saline and bitter taste. The aqueous solution is neutral or slightly acid to methyl red. The 10 per cent. aqueous solution gives with sodium hydroxide a white precipitate which soon changes into oily drops and is soluble in ether and chloroform. On adding 25 millilitres of ether to about 0·1 gramme of the salt, then a few drops, but not an excess, of solution of ammonia, and afterwards an ethereal solution of iodine, 1 in 50, until the solution on shaking turns from orange to dark reddish-brown in colour, the sides of the vessel containing the solution become covered in a short time with minute, dark greenish-brown crystals. The specific rotation, determined on a 10 per cent. w/v solution of the hydrated salt and calculated for anhydrous sparteine sulphate, is about $-27\cdot6^\circ$.

Soluble in water (2 in 1) and alcohol (1 in 5); insoluble in ether and chloroform.

Standard.—Sparteine sulphate, after drying at 115° , does not melt below 150° . Loss on drying at 110° , not less than 20 per cent. and not more than 22 per cent. Ash, not more than 0·1 per cent.

Action and Uses.—Sparteine resembles coniine in its general effects, but it is very much less poisonous. It has little action on the central nervous system, but large doses paralyse sympathetic nerve cells and the peripheral terminations of the motor nerves. Depression of autonomic nerve cells causes a fall in blood pressure with vasodilatation, and its employment has been recommended in cases of high blood pressure. It does, however, act as a cardiac depressant, the rhythm being slow and the contraction weak. Sparteine sulphate is the most

commonly used salt of the base and has been given in doses as large as 0·8 gramme (12 grains). It is **administered** in pills, or by hypodermic injection in doses of from 0·12 to 0·4 millilitre (2 to 6 minims) of a 15 per cent. solution. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0·06 to 0·12 gramme (1 to 2 grains).

SPARTEINA.—Sparteine, $C_{15}H_{25}N_2$, is a volatile, liquid alkaloid obtained from scoparium. It occurs as a transparent, oily liquid, colourless when freshly prepared, but absorbing oxygen under the influence of air and light and becoming yellowish to dark brown in colour, and thicker; it is heavier than water, and has a penetrating odour resembling that of aniline and an intensely bitter taste. The aqueous solution is strongly alkaline. It is sparingly soluble in water, soluble in alcohol, ether and chloroform, but insoluble in benzene and petroleum oils.

SPIRITUS METHYLATUS INDUSTRIALIS

(Sp. Meth. Indust.)

Industrial Methylated Spirit

Synonym—Industrial Methylated Spirits.

Industrial methylated spirit is a mixture made by a legally authorised methylator of 19 volumes of alcohol (95 per cent.) with 1 volume of approved wood naphtha, and is of the quality known as “66 O.P. Industrial Methylated Spirits”. It is a colourless, transparent, mobile and volatile liquid with a burning taste and an odour of alcohol and of wood naphtha. 0·5 millilitre diluted with water to 5 millilitres and tested for methyl alcohol as described in the British Pharmacopœia gives an intensely violet-coloured solution. This spirit is also obtainable in other strengths, one of the most common being “64 O.P. Industrial Methylated Spirits”.

Standard, B.P.—Industrial methylated spirit has a specific gravity not higher than 0·817. Residue on evaporation and drying at 100°, not more than 0·01 per cent. w/v. It complies also with limit tests for acidity, alkalinity and for oily and resinous substances.

Uses.—Industrial methylated spirit is now widely used in pharmacy. The Board of Customs and Excise permit, subject to the observance of the conditions laid down in their regulations, the use of industrial duty-free spirit in the preparation of a range of specified preparations intended for external use only. These scheduled preparations include certain inhalations, liniments, lotions, parogens, sprays, spirits, solutions and tinctures of the British Pharmacopœia or British Pharmaceutical Codex, in addition to a formulary of medicinal, surgical, toilet and other preparations. Industrial methylated spirit may also be used in the preparation of certain extracts, resins and surgical dressings, provided that in each case no alcohol remains in the finished product. Provisions governing the dispensing, on the prescriptions of qualified

medical, dental and veterinary practitioners, of industrial methylated spirit or preparations of which it is an ingredient and its utilisation in ways other than those mentioned, are also contained in the regulations issued by the Board of Customs and Excise. Industrial methylated spirit, as usually supplied, contains acetone and should not be used for the preparation of iodine solutions, since an irritating compound is formed by reaction between the iodine and acetone; for such preparations industrial methylated spirit (acetone-free) is used. In cases of **poisoning** by industrial methylated spirit or mineralised methylated spirit the procedure described under Alcohol Methylicum should be adopted.

Preparation

Spiritus Chirurgicalis, B.P.C.—(Sp. Chir.)—Surgical Spirit. No. 1 contains industrial methylated spirit with castor oil, 2·5 per cent., methyl salicylate and ethyl phthalate. No. 2 contains industrial methylated spirit with castor oil, 2·75 per cent., mineral naphtha and ethyl phthalate.

SPIRITUS METHYLATUS INDUSTRIALIS SINE ACETONO

(Sp. Meth. Indust. s. Aceton.)

Industrial Methylated Spirit (Acetone-free)

Industrial methylated spirit (acetone-free) is a mixture, made by a legally authorised methylator, of 19 volumes of alcohol (95 per cent.) with 1 volume of approved wood naphtha or other approved denaturant, and is of the quality known as "66 O.P. Industrial Methylated Spirits," but free from acetone. It is a colourless, transparent, mobile and volatile liquid, with a burning taste and an odour of alcohol and of wood naphtha. 0·5 millilitre diluted with water to 5 millilitres and tested for methyl alcohol as described in the British Pharmacopœia gives an intensely violet-coloured solution.

Standard.—Industrial methylated spirit (acetone-free) has a specific gravity not greater than 0·817. It complies with the limit tests for residue on evaporation and drying at 100°, acidity, alkalinity, and for oily and resinous substances in Spiritus Methylatus Industrialis. Dilute 5 millilitres with water to 10 millilitres and add 1 millilitre of 1 per cent. solution of *o*-nitrobenzaldehyde in alcohol (50 per cent.), followed by 1 millilitre of 15 per cent. w/v sodium hydroxide solution; the colour produced at the end of fifteen minutes is not greater than that produced by similarly treating 10 millilitres of 0·025 per cent. v/v solution of acetone in alcohol (50 per cent.) (limit of acetone).

Uses.—Industrial methylated spirit (acetone-free) is used in the preparation of iodine paint and other spirituous solutions of iodine intended for external use instead of ordinary industrial methylated spirit, the acetone content of which is very liable to produce irritating vapours when solutions of iodine are used over large areas, as in pre-operative work.

STAPHISAGRIA

(Staphisag.)

Staphisagria*Synonyms*—Staphisagriae Semina; Stavesacre Seeds.

Staphisagria consists of the seeds obtained from *Delphinium Staphisagria* Linn. (Fam. Ranunculaceæ), a herb indigenous to Asiatic Turkey and Southern Europe and cultivated in France and Italy.

The seeds, which are pointed at one end, are from 6 to 8 millimetres in length and breadth, obscurely four-sided and of irregular pyramidal shape, one side being distinctly arched and broader than the others, which are flattened. Usually they appear grey in colour, but when freed from the dust with which they are covered, are seen to be dark brown. The surface is coarsely reticulated and covered with minute papillæ. Near the pointed end the hilum can be seen as a narrow line. A vertical section passing through the hilum shows a minute embryo embedded in a large, yellowish-white, oily endosperm. The seed coats are tasteless, but the endosperm is bitter and acrid.

The diagnostic **microscopical** characters are the brown epidermal cells varying in size and shape, with strongly thickened walls characterised by ridges which project from the outer wall; the polygonal cells of the inner layer of the testa, exhibiting wrinkles which take the form of linear projections; the cells of the endosperm containing granular protein together with fixed oil.

Staphisagria **contains** about 1 per cent. of alkaloids, the most important of which are delphinine, $C_{34}H_{47}O_9N$, (rhombic crystals, which begin to decompose at 120° , before the melting-point is reached), delphisine and delphinidine, with traces of staphisagroine. It also contains about 25 to 35 per cent. of fixed oil which, on expression, carries with it the greater part of the alkaloid. The ash varies from 10 to 15 per cent.

Action and Uses.—Staphisagria is used chiefly in the form of ointment and lotion to destroy pediculi. An ointment may also be prepared by mixing the fixed oil with seven parts of benzoinated lard. Delphinine resembles aconitine in its physiological action.

Preparations

Lotio Staphisagriae, B.P.C.—(Lot. Staphisag.)—Stavesacre Lotion. *Syn.*—Nursery Hair Lotion. Stavesacre, 10 per cent. w/v, with acetic acid, alcohol (90 per cent.), glycerin and distilled water, perfumed with oils of geranium, lavender and lemon.

Unguentum Staphisagriae, B.P.C.—(Ung. Staphisag.)—Stavesacre Ointment. A mixture of yellow beeswax and benzoinated lard in which stavesacre, about 20 per cent., has been digested.

This ointment was included in the British Pharmacopœia, 1914.

STILLINGIA

(Stilling.)

Stillingia*Synonyms*—Queen's Root; Yaw Root.

Stillingia is the dried root of *Stillingia sylvatica* Linn. (Fam. Euphorbiaceæ), a perennial plant indigenous to the United States of America. Stillingia should not be **stored** for a longer period than two years after the date of collection.

The root occurs in slenderly fusiform or cylindrical pieces of various lengths, usually about 15 to 20 centimetres, and from 0.5 to 2 centimetres in thickness; occasionally very long, fibrous rootlets are attached. Externally, the root is reddish brown and finely or coarsely wrinkled longitudinally, the thicker pieces showing transverse cracks at intervals. It breaks with a fibrous fracture, the fractured surface being whitish in the bark and cinnamon-brown in the wood. The smoothed, transverse surface shows a wide, starchy bark containing numerous resin cells, and a central, porous wood which is easily separable from the bark. The drug has a characteristic odour and the taste is slightly bitter and acrid.

Stillingia **contains** sylvacrol (an acrid resin), fixed oil, volatile oil (3 to 4 per cent.), together with tannin, starch and calcium oxalate.

Standard.—Stillingia contains not more than 2 per cent. of foreign organic matter.

Action and Uses.—Stillingia, by virtue of its mildly irritant properties, acts reflexly as a sialagogue and expectorant. In large doses it has emetic and cathartic properties.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

STRAMONII SEMEN

(Stramon. Sem.)

Stramonium Seed*Synonym*—Thornapple Seed.

Stramonium seed consists of the seeds of *Datura Stramonium* Linn. (Fam. Solanaceæ), a bushy annual plant about three feet in height growing throughout the warmer temperate regions.

The seeds are flattened and reniform in shape, measuring about 3 millimetres in length, 2 millimetres in width and 1 millimetre in thickness. The hilum appears as a light spot on the concave edge. They vary in colour from purple to nearly black. The seed coat is finely pitted and shows a network of more or less well-marked, characteristic, reticulate depressions. A section cut parallel to the flat surface of the seed shows a whitish, curved embryo embedded in a

translucent, oily endosperm. The seeds have a scarcely perceptible odour, and the taste is somewhat bitter and oily.

The diagnostic **microscopical** characters are the large sclerenchymatous cells of the epidermis, not exceeding 350 microns in height, having dark-coloured walls and narrow lumina, but without pits in the basal walls, and the cells of the endosperm containing oil and aleurone grains which frequently show a distinct crystalloid and globoid.

Stramonium seed **contains** from about 0.1 to about 0.5 per cent. of alkaloid, the average being about 0.2 per cent., consisting chiefly of hyoscyamine associated with small quantities of atropine and hyoscine; it also contains from 15 to 30 per cent. of fixed oil; the latter has a specific gravity of about 0.919 and contains daturic and other acids. The ash is about 5 per cent.

Action and Uses.—The properties of stramonium seed resemble those of stramonium leaf.

STRAMONIUM

(Stramon.)

Stramonium

Synonyms—Stramonii Folia; Stramonium Leaves; Thornapple Leaves.

Stramonium consists of the dried leaves and flowering tops of *Datura Stramonium* Linn. and of *D. tatula* Linn. (Fam. Solanaceæ), bushy annuals cultivated in England, Germany, Hungary and the United States of America. The leaves and young shoots are collected while the plant is in flower, from about June to September.

The leaves are dark greyish-green and much shrivelled and twisted as the result of drying; when expanded they are ovate or triangular-ovate in outline, with a sinuate-dentate margin, 8 to 25 centimetres long and 7 to 20 centimetres broad. The apex is acuminate and the base usually unequal. The petiole is often short and twisted. The young leaves bear numerous trichomes, but the older ones are almost glabrous. The stems are dichotomously branched. The flowers occur solitary at the forks and are about 7.5 centimetres long, erect and shortly pedicellate; the corolla is white or purplish-blue, plicate and funnel-shaped. The ovary is superior, conical, spuriously tetralocular in the lower part, and covered with short, stiff emergences. The odour is disagreeable and characteristic, and the taste is unpleasant and bitter.

The diagnostic **microscopical** characters are the smooth cuticle and wavy anticlinal walls of the epidermal cells; the stomata of the cruciferous type, rare in the upper epidermis, but numerous in the lower; straight or slightly curved, uniseriate, conical trichomes with thin, warty walls, usually 3-celled, the basal cell being the largest and usually exceeding 50 microns in length and 35 microns in breadth; the glandular trichomes which are usually curved and composed of a short 1- or 2-celled pedicel and a 2- to 7-celled glandular head; the single row of palisade

cells and, beneath it, the crystal layer containing in most of the cells a single cluster-crystal of calcium oxalate or occasional prisms or micro-sphenoidal crystals; the presence of perimedullary phloem in the midrib; the trichomes of the stem epidermis, resembling those of the leaf but often attaining a length of 800 microns; the occasional pericyclic fibres; the numerous wood fibres and vessels; the crystal sacs and perimedullary phloem of the stems.

Stramonium **contains** from 0.3 to 0.5 per cent. of alkaloid, which consists chiefly of hyoscyamine, associated with atropine and hyoscine.

Varieties.—The leaves and stems of *Datura Stramonium* are green in colour and the corollas of the flowers are white. The stems and petioles of *D. tatula* are tinted with red and the corollas are purplish-blue; the leaves are a somewhat darker green than those of *D. Stramonium*. Stramonium is sometimes imported in a broken (laminated) condition and is then not infrequently adulterated.

Substitutes.—The leaves of *Xanthium Strumarium* Linn. (Fam. Compositæ) have large, usually 3-celled, conical hairs containing cystoliths, and have no cluster-crystals of calcium oxalate. The leaves of *Carthamus helenioides* Desf. (Fam. Compositæ) have large epidermal cells with straight walls and striated cuticle, no cluster-crystals, and well-developed secreting ducts. Those of *Chenopodium hybridum* Linn. (Fam. Chenopodiaceæ) have small epidermal cells with nearly straight walls, and trichomes terminated by a large, bladderly, water-storing cell.

Standard, B.P.—Stramonium contains not more than 2 per cent. of foreign organic matter, not more than 20 per cent. of its stem, not more than 1 per cent. of its stem having a width greater than 4 millimetres and not less than 0.25 per cent. of the alkaloids of stramonium, calculated as hyoscyamine. Ash, not more than 20 per cent. Acid-insoluble ash, not more than 4 per cent.

Stramonium, in powder (Pulvis Stramonii : Pulv. Stramon.), contains the constituents and possesses the diagnostic microscopical characters of Stramonium, and complies with the standard for alkaloids. ash and acid-insoluble ash of the unground drug.

Action and Uses.—The properties of stramonium are virtually those of the alkaloid, hyoscyamine. The drug is used chiefly to relieve the spasmodic contractions of the bronchioles in asthma; it paralyzes the peripheral ends of the vagi in the bronchioles, so that the latter relax. Stramonium, in doses of 2½ grains three times a day, increased to 15 or 20 grains daily, is used for the sequelæ of encephalitis lethargica. Definite improvement has been observed following the administration of large doses, but too rapid an increase of dosage may lead to paralysis of accommodation. The leaf is smoked in cigarettes and is an ingredient of Pulvis Stramonii Compositus and other powders intended to be burnt for asthma, but the use of such powders is not to be recommended owing to the vicious circle set up by the irritant fumes resulting from combustion. Stramonium is **administered** in pills or tablets, as Tinctura Stramonii in mixture form, often with tincture of lobelia and potassium iodide, or as extract or liquid extract. In cases of **poisoning** by stramonium the procedure described under Atropina should be followed.

Dose.—0.03 to 0.2 gramme (½ to 3 grains).

Preparations

Extractum Stramonii, B.P.C.—(Ext. Stramon.)—Extract of Stramonium. This extract contains from 0.95 to 1.05 per cent. of the alkaloids of stramonium; 0.06 gramme contains about 0.0006 gramme, and 1 grain contains about $\frac{1}{100}$ grain, of alkaloids. Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

Extractum Stramonii Liquidum, B.P.C.—(Ext. Stramon. Liq.)—Liquid Extract of Stramonium. This liquid extract contains from 0.225 per cent. to 0.275 per cent. of the alkaloids of stramonium; 0.2 millilitre contains about 0.0005 gramme, and 3 minims contains about $\frac{1}{100}$ grain, of alkaloids. Dose.—0.03 to 0.2 millilitre ($\frac{1}{4}$ to 3 minims).

Mistura Lobeliae et Stramonii Composita, B.P.C.—(Mist. Lobel. et Stramon. Co.)—Compound Mixture of Lobelia and Stramonium. Each fluid ounce contains 4 grains of ammonium carbonate, 5 grains of potassium iodide and 10 minims each of ethereal tincture of lobelia and tincture of stramonium, in chloroform water. Dose.—15 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

Pulvis Lobeliae Compositus, B.P.C.—(Pulv. Lobel. Co.)—Compound Lobelia Powder. Equal parts of lobelia, stramonium and tea, impregnated with potassium nitrate and oil of anise.

Pulvis Stramonii Compositus, B.P.C.—(Pulv. Stramon. Co.)—Compound Stramonium Powder. Stramonium, 1 in 2, with lobelia, anise and tea, impregnated with potassium nitrate and oil of eucalyptus.

Tinctura Stramonii, B.P.—(Tinct. Stramon.)—Tincture of Stramonium. It is prepared by percolation with alcohol (45 per cent.), and contains 0.025 per cent. w/v of the alkaloids of stramonium, calculated as hyoscyamine (limit, 0.0225 to 0.0275); 2 millilitres contains 0.0005 gramme, and 30 minims contains about $\frac{1}{100}$ grain, of alkaloids. It is approximately half the strength of the corresponding preparation of the British Pharmacopœia, 1914. Dose.—0.3 to 2 millilitres (5 to 30 minims).

Unguentum Stramonii, B.P.C.—(Ung. Stramon.)—Stramonium Ointment. Extract of stramonium, 10 per cent., in hydrous wool fat and benzoinated lard.

STRONTII BROMIDUM

(Stront. Brom.)

Strontium Bromide

Strontium bromide may be prepared by treating diluted hydrobromic acid with a slight excess of strontium carbonate, filtering the mixture, and evaporating the filtrate until crystals begin to form. On cooling, the separated salt is collected and carefully dried at a moderate heat. It occurs in colourless, transparent, odourless crystals which are very deliquescent and have a bitter, saline, unpleasant, metallic taste. It is precipitated from an alcoholic solution on the addition of an equal volume of ether. The aqueous solution is neutral to litmus and deposits a crystalline precipitate on the addition of calcium sulphate solution. On heating, the salt first melts in its water of crystallisation and then becomes anhydrous at 120° to 130°. The anhydrous salt melts at about 630° without decomposition. It should be **stored** in well-closed containers.

Soluble in water (2 in 1) and alcohol (1 in 3); insoluble in ether.

Standard.—Strontium bromide, determined by the method of the British Pharmacopœia for Potassii Bromidum, contains not less than 97 per cent. of $\text{SrBr}_2 \cdot 6\text{H}_2\text{O}$; each millilitre of N/10 silver nitrate is equivalent to 0.01778 gramme of $\text{SrBr}_2 \cdot 6\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. Lead limit, 20 parts per million. It complies with the limit tests for chloride and bromate in Potassii Bromidum. 2 grammes complies with the limit test for sulphates. 0.5 gramme complies with the limit test for iron. Dissolve 2 grammes in 10 millilitres of dilute acetic acid and add a few drops of potassium dichromate solution; no turbidity appears within three minutes (limit of barium).

Action and Uses.—Strontium salts are somewhat similar in action to calcium salts; they are absorbed very slowly from the intestine and are excreted chiefly by the bowel. Strontium bromide is sometimes used in place of potassium bromide and it is stated, erroneously, to be less depressing than the latter; it is also said to be less liable to produce a rash. Owing to its slower rate of absorption, it is not so useful in epilepsy as potassium bromide. It is **administered** in solution in mixture form. Strontium salts are **incompatible** with alkali carbonates and bicarbonates.

Dose.—0.3 to 2 grammes (5 to 30 grains).

STRONTII IODIDUM

(Stront. Iod.)

Strontium Iodide

Strontium iodide may be prepared by neutralising hydriodic acid with strontium carbonate, filtering the solution, concentrating and crystallising. It occurs in colourless, transparent, odourless plates or crystalline masses which are deliquescent and have a bitter, saline taste. When cautiously heated, the crystals melt and gradually lose their water of crystallisation; at a red heat, the salt is decomposed, losing iodine. An aqueous solution is neutral or faintly alkaline to litmus. It should be **stored** in well-closed containers.

Soluble in water (2 in 1) and alcohol; slightly soluble in ether.

Standard.—Strontium iodide, determined by the method of the British Pharmacopœia for Potassii Iodidum, contains not less than 99 per cent. of $\text{SrI}_2 \cdot 6\text{H}_2\text{O}$; each millilitre of M/20 potassium iodate is equivalent to 0.02248 gramme of $\text{SrI}_2 \cdot 6\text{H}_2\text{O}$. Arsenic limit, 2 parts per million. Lead limit, 20 parts per million. 2 grammes complies with the limit test for sulphates. Dissolve 2 grammes in 10 millilitres of dilute acetic acid and add a few drops of potassium dichromate solution; no turbidity appears within three minutes (limit of barium).

Action and Uses.—Strontium iodide possesses properties similar to those of the alkali iodides and has been used in chronic endocarditis, asthma and rheumatism.

Dose.—0.3 to 1 gramme (5 to 15 grains).

STROPHANTHINUM

(*Strophanthin*.)

Strophanthin

Synonyms—Kombé Strophanthin; K-Strophanthin.

Strophanthin is a mixture of glycosides obtained from *Strophanthus kombé*. It consists of cymarín, k-strophanthin- β , and other glycosides, and may be isolated from the freshly powdered seeds by extracting first with ether or carbon disulphide to remove fat and then with alcohol, the latter being distilled off, the residue dissolved in water and the solution filtered. The filtrate is treated with tannic acid and the washed precipitate mixed with lead oxide, dried, and extracted with alcohol. On adding excess of ether to the alcoholic solution, strophanthin is precipitated; it is collected, and dried *in vacuo*. Strophanthin is adjusted to the required standard by admixture with lactose. The undiluted mixture of glycosides occurs as a white or yellowish-white powder which may contain microcrystalline particles. The aqueous solution is neutral to litmus and is dextrorotatory. By decomposition with dilute mineral acids, strophanthin is hydrolysed into strophanthidin and a biose. Strophanthin may be distinguished from ouabain by dissolving a small quantity in a cold mixture of 4 volumes of sulphuric acid and 1 volume of water, when an emerald-green colouration is produced. Strophanthin should be **stored** in well-closed containers and protected from light.

Soluble in water and alcohol (90 per cent.); less soluble in dehydrated alcohol; sparingly soluble in chloroform; almost insoluble in ether, benzene and light petroleum.

Standard, B.P.—Strophanthin is adjusted by admixture with lactose so that it possesses an activity equal to 40 per cent. of that of the international standard ouabain. A standard preparation of strophanthin for use in Great Britain and Northern Ireland, of known potency compared with the international standard ouabain, is kept in the National Institute for Medical Research, London. Loss on drying in a vacuum desiccator over sulphuric acid, not more than 3 per cent. Ash, not more than 1 per cent.

Action and Uses.—Strophanthin acts on the heart in a manner similar to that of digitalis, but while digitalis produces marked peripheral vasoconstriction, strophanthin is almost without this action. For this reason it is to be preferred when the heart is weak. It is absorbed more rapidly, is non-cumulative, and is less likely to produce gastro-intestinal irritation than digitalis; it occasionally, however, causes

diarrhœa. It is a more efficient diuretic since it raises blood pressure without producing constriction of the renal vessels, so that more blood passes through the kidneys. It is an extremely powerful poison, arresting the action of the heart in systole, and it should be used with caution. It should be **administered** intramuscularly or intravenously; subcutaneous injections are absorbed less readily and may give rise to inflammation. Small doses have been given intravenously with great success in urgent cases. A solution for **injection** is prepared by aseptic methods and transferred to sterilised containers which are afterwards sealed to exclude bacteria; the solution is then heated to 80° for one hour and should be used within twenty-four hours. In cases of **poisoning** by strophanthin, the procedure described for *Strophanthus* should be adopted.

Dose.—0·00025 to 0·001 gramme ($\frac{1}{4000}$ to $\frac{1}{1000}$ grain), by intramuscular or intravenous injection.

OUABAINUM.—Ouabain, or g-strophanthin, is present in the wood of *Acokanthera Schimper* Oliver (Fam. Apocynaceæ), and is obtained from the seeds of *Strophanthus gratus* Franch. It crystallises with about 12 per cent. of water of crystallisation and is rendered anhydrous by heating at 130°. It begins to soften at about 180°, and gives a red colouration with sulphuric acid. The specific rotation of anhydrous ouabain is from $-31\cdot3^\circ$ to $-31\cdot9^\circ$. Ouabain is nearly twice as toxic as k-strophanthin, and is used as an international standard for the control of the standard preparation of strophanthin which is used for the biological assay of strophanthin and tincture of strophanthus. The standard preparation of strophanthin is compared with international standard ouabain by the frog method, and issued by the National Institute for Medical Research, London. The standard tincture of strophanthus is equivalent in activity to a 0·42 per cent. w/v solution of the standard ouabain, or to a 0·33 per cent. w/v solution of anhydrous ouabain, when the comparison is made by the frog method.

STROPHANTHUS

(*Strophanth.*)

Strophanthus

Synonyms—*Strophanthi Semina*; *Strophanthus Seeds*.

Strophanthus consists of the dried, ripe seeds, freed from the awns, of *Strophanthus kombé* Oliver (Fam. Apocynaceæ), a climbing plant indigenous to tropical East Africa.

The seeds are about 12 to 18 millimetres long, 3 to 5 millimetres broad and 2 millimetres thick, lanceolate to linear-lanceolate, with a truncated-acuminate apex and an obtuse and slightly winged base. The surface is silky, due to appressed hairs directed towards the apex, the colour being feebly greyish-green or greenish-fawn. A ridge runs longitudinally from the centre of the ventral side to the apex. Within the testa, a narrow, oily endosperm surrounds a large, white, straight embryo with oily cotyledons. The odour is characteristic and the taste is very bitter.

The diagnostic **microscopical** characters are the outer epidermal cells of the testa, elongated-polygonal in shape, with straight, thickened and lignified anticlinal walls, many extended into trichomes each having on the under side a single, longitudinal, lignified rib; the occasional cluster-crystals and single prisms of calcium oxalate in the cells of the testa; the parenchyma of the endosperm and embryo containing aleurone grains and fixed oil. When treated with a drop of sulphuric acid (66 per cent. v/v), the endosperm exhibits an intense green colour.

Strophanthus contains from 7 to 10 per cent. of a mixture of glycosides, known as k-strophanthin, together with about 25 per cent. of fixed oil. K-strophanthin consists of cymarín, k-strophanthin- β and other glycosides, and yields on hydrolysis with a dilute mineral acid strophanthidin and a biose. The drug also contains kombic acid, choline and trigonelline.

Substitutes.—The seeds of *Strophanthus hispidus* DC. are smaller and brownish in colour; they bear scattered hairs, the greater part having been removed by friction; they give a green colouration with sulphuric acid; only a few clusters and prisms of calcium oxalate are present in the seed coat. The seeds of *S. Courmonti* Sacl. have a brownish tinge, and are smaller in size, more lanceolate, less bitter, and have abundant prismatic crystals of calcium oxalate in the testa; they give a red to violet colouration with sulphuric acid. The seeds of *S. Nicholsoni* Holmes have a covering of whitish, woolly hairs; calcium oxalate is absent; they give a red colouration with sulphuric acid. The seeds of *S. gratus* Franch. are brown, and glabrous to the naked eye, the trichomes being reduced to conical papillæ; calcium oxalate is absent; they give a red colouration with sulphuric acid and contain the glycoside, ouabain (known also as g-strophanthin), which is more toxic than strophanthin. The seeds of *S. Emini* Aschers are shining brownish-yellow, being thickly covered with hairs; they give a red to violet colouration with sulphuric acid; calcium oxalate crystals are absent. The seeds of *S. sarmentosus* DC. are reddish-brown to greenish; the trichomes are yellowish and easily break off; cluster-crystals of calcium oxalate are abundant in the cotyledons, while both single crystals and clusters occur in the seed coat; with sulphuric acid they give a pale rose-red colouration.

Standard, B.P.—Strophanthus contains not more than 2 per cent. of foreign organic matter. Ash, not more than 5 per cent.

Action and Uses.—The properties of strophanthus are virtually those of strophanthin. Strophanthus is used in place of digitalis when a rapid cardiac action is required, since tincture of strophanthus acts in from half to one hour, whilst tincture of digitalis requires from thirty-six to forty-eight hours. Strophanthus differs from digitalis not only in its smaller effect on blood vessels, but in its smaller action on the vagus nerve. It does not, therefore, slow the heart to the same extent as digitalis. It is, however, undoubtedly a more dangerous drug to use since it is easily absorbed and much more readily induces delirium cordis. In mitral disease with sudden failure of compensation, and in the cardiac weakness of pneumonia and other acute illnesses, strophanthus is of especial value and it sometimes succeeds when digitalis fails. In some cases it has been found an advantage to give alternate courses of strophanthus and digitalis. The tincture is the most generally used preparation of strophanthus; it is extremely rapid in its action and should be given in small doses, 0.12 to 0.3 millilitre (2 to 5 minims).

In cases of **poisoning** by *strophanthus*, the stomach pump should be employed or emetics given, followed in either case by an aqueous solution of gallic or tannic acid and stimulants. The heart becomes very rapid, beats are dropped and later become uncountable, resulting in the condition known as "delirium cordis." Death occurs suddenly. Everything should be done which is likely to depress the increased irritability of the heart; inhalations of chloroform are most likely to be successful.

Preparations

Extractum Strophanthi, B.P.C.—(Ext. *Strophanth.*)—Extract of *Strophanthus*.

A dry extract, 1 in 2. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

This extract was included in the British Pharmacopœia, 1914.

Tinctura Strophanthi, B.P.—(Tinct. *Strophanth.*)—Tincture of *Strophanthus*.

It is prepared by percolating *strophanthus*, previously defatted with light petroleum, with alcohol (70 per cent.), and possesses a degree of activity equivalent to that of the standard tincture of *strophanthus*. Dose.—0·12 to 0·3 millilitre (2 to 5 minims).

Tinctura Strophanthi I.A. is prepared with alcohol (70 per cent.) from 10 per cent. w/w of the defatted seeds of *Strophanthus hispidus* or *S. kombé*. *Tinctura Strophanthi grati I.A.* is prepared with alcohol (70 per cent.) from 10 per cent. w/w of the defatted seeds of *S. gratus*.

STRYCHNINA

(Strych.)

Strychnine

Strychnine is the chief alkaloidal constituent of the seeds of various species of *Strychnos*. It may be prepared by extracting a mixture of ground nux vomica beans and slaked lime with benzene, the total alkaloids being subsequently transferred to dilute sulphuric acid, from which the bases are again regenerated by sodium hydroxide solution. Crude strychnine may be obtained by crystallisation from alcohol, and may be purified by conversion into, and recrystallisation of, the sulphate. The alkaloid may be precipitated by ammonia from an aqueous solution of the sulphate thus obtained and then recrystallised from boiling alcohol.

Strychnine occurs in the form of translucent, trimetric, odourless, colourless, anhydrous prisms or as a white, crystalline powder, having an extremely bitter and afterwards metallic taste; it is very poisonous. The aqueous solution is intensely bitter, the bitterness being discernible in a solution of 1 in 700,000. Strychnine melts, with decomposition, between 270° and 280°. The specific rotation in alcohol is about -133° . It is precipitated by alkalis from its acid solutions. Even very dilute solutions of strychnine salts yield precipitates with the usual alkaloidal reagents. Sulphuric acid containing 1 per cent. of ammonium vanadate gives a deep violet-blue colour, changing to deep purple, and

on dilution with water a cherry-red colour is produced which persists for some time. When a small fragment is dissolved in 2 or 3 drops of sulphuric acid on a white porcelain plate, and a small crystal of potassium dichromate is slowly moved through the solution, an intense violet colour is produced which passes through red to yellow.

Soluble in water (about 1 in 7000), boiling water (1 in 2500), alcohol (90 per cent.) (1 in 150), boiling alcohol (90 per cent.) (1 in 12), dehydrated alcohol (1 in 350), boiling dehydrated alcohol (1 in 40) and chloroform (1 in 6), benzene (1 in 160); nearly insoluble in ether.

Standard.—Strychnine contains not less than 99 per cent. of $C_{21}H_{22}O_2N_2$. Ash, not more than 0.1 per cent. 0.25 gramme dissolves in 5 millilitres of sulphuric acid, the solution being not more than faintly yellow (limit of readily carbonisable impurities). To 0.1 gramme add 1 millilitre of a mixture of equal parts of nitric acid and water; a yellow but not a red or reddish colour is produced (limit of brucine).

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 10 millilitres of N/10 sulphuric acid and titrate with N/10 sodium hydroxide using solution of cochineal as indicator; each millilitre of N/10 sulphuric acid is equivalent to 0.03342 gramme of $C_{21}H_{22}O_2N_2$.

Action and Uses.—Strychnine has the action of a bitter in the mouth, increasing the appetite and augmenting the flow of gastric juice. It is rapidly absorbed as it reaches the intestines, the alkaloid and its salts being more readily absorbed than the preparations of *nux vomica*. After absorption strychnine exerts its characteristic effects upon the central nervous system. Through its action on the sensory portion of the cord, the reflexes are exaggerated and the normal tonus of striped muscle increased. The medulla is stimulated, the movements of respiration are deepened and quickened, peripheral vessels are constricted through stimulation of the vasomotor centre, and the heart slowed through excitation of the vagal centre. The sense organs are stimulated, so that the senses of smell, touch, hearing and vision are rendered more acute. The blood pressure is raised by the vasoconstriction produced, so that strychnine improves the pulse and is a valuable tonic to the circulatory system in cardiac failure. Strychnine acts as an aphrodisiac in the male, on account of its action in augmenting the reflexes of the cord. It reflexly increases the tonus of plain muscle, and also has a direct stimulant effect, so that it is of value in such conditions as chronic constipation, atony of the bladder, etc. Strychnine is excreted very slowly, and its action is therefore cumulative. Warning signs are increased reflexes and twitching of muscles.

Strychnine is much used as a gastric tonic in dyspepsia and as a general tonic in convalescence from acute disease; with atropine it is used hypodermically, and by the mouth in dipsomania. It is **administered** as solution of the hydrochloride in mixture form, often with mineral acids, or in pills, or in syrups such as Easton's syrup and compound syrup of hypophosphites. It is added to aperient pills to increase

peristalsis, but preparations of *nux vomica* are often preferred for this purpose. It is used in surgical shock and in cardiac failure, large doses, up to 0.006 gramme ($\frac{1}{16}$ grain), being given by hypodermic injection. It is also added to solutions of local anæsthetics for high intraspinal injections (0.0005 to 0.001 gramme) to prevent respiratory failure, but it is not uniformly successful for this purpose. It is used as an antidote in chloral and chloroform poisoning. Strychnine, given hypodermically in the form of strychnine nitrate in doses varying from 0.004 gramme ($\frac{1}{16}$ grain) up to as much as 0.067 gramme ($\frac{1}{8}$ grain), has been used with success in the treatment of snake bite.

Symptoms of poisoning may supervene suddenly, with tremors, twitching of limbs and violent convulsions; the body becomes rigid; the face muscles become contracted, producing a characteristic grinning expression known as "risus sardonicus." In cases of **poisoning** by strychnine, apomorphine by injection, emetics, or the stomach pump should be used, and tannin or potassium permanganate administered to render the strychnine inactive, or charcoal in fine powder may be given to adsorb the poison. The convulsions are controlled by chloroform anæsthesia, or by large doses of chloral or bromide. The administration of urethane in large doses (10 to 20 grammes), or the intravenous injection of soluble barbitone or soluble phenobarbitone, is considered of value as an antidotal measure. Artificial respiration or inhalation of oxygen containing 10 per cent. v/v of carbon dioxide is employed if paralysis intervenes. Strychnine is the principal ingredient of many vermin killers.

Dose.—0.002 to 0.008 gramme ($\frac{1}{80}$ to $\frac{1}{8}$ grain).

Preparations

Pilulæ Aloini et Strychninæ Compositæ, B.P.C.—(Pil. Aloin. et Strych. Co.)—Compound Aloin and Strychnine Pills. Each pill contains $\frac{1}{8}$ grain of aloin, $\frac{1}{80}$ grain of strychnine, $\frac{1}{16}$ grain of dry extract of belladonna, and $\frac{1}{80}$ grain of powdered ipecacuanha. Dose.—1 or 2 pills.

Syrupus Ferri Bromidi cum Quinina et Strychnina, B.P.C.—(Syr. Ferr. Brom. c. Quinin. et Strych.)—Syrup of Ferrous Bromide with Quinine and Strychnine. Strychnine, about 0.03 per cent. w/v, and quinine dihydrobromide, 2 per cent. w/v, with dilute hydrobromic acid, distilled water and syrup of ferrous bromide; each fluid drachm contains about $\frac{1}{80}$ grain of strychnine, $\frac{1}{16}$ grains of quinine dihydrobromide and 4 grains of ferrous bromide. Dose.—2 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

STRYCHNINÆ HYDROCHLORIDUM

(Strych. Hydrochlor.)

Strychnine Hydrochloride

Strychnine hydrochloride may be prepared by dissolving strychnine

in hydrochloric acid and crystallising from neutral solution. It crystallises with a slightly variable proportion of water of crystallisation, corresponding to from $1\frac{1}{2}$ to 2 molecules. Strychnine hydrochloride occurs in colourless, odourless, prismatic crystals, having an intensely bitter taste. It is permanent in air. The aqueous solution is neutral to litmus and is lævorotatory. The salt is less soluble in acid solutions than in water, and is precipitated from a 1 per cent. aqueous solution on the addition of hydrochloric acid. On the addition of alkalis to the aqueous solution, the alkaloid is precipitated. It responds to the tests with sulphuric acid and potassium dichromate and ammonium vanadate described under Strychnina. With platinum chloride it yields a yellowish-white precipitate which is almost insoluble in water and separates from hot diluted alcohol in golden crystals. It loses its water of crystallisation at 110° , but is not decomposed, even at 150° .

Soluble in water (about 1 in 40) and alcohol (90 per cent.) (about 1 in 80); insoluble in ether.

Standard, B.P.—Strychnine hydrochloride loses, on drying at 110° , not less than 7 per cent. and not more than 9 per cent. of its weight. Ash, not more than 0.1 per cent. It complies also with limit tests for brucine, sulphate and readily carbonisable substances.

Action and Uses.—Strychnine hydrochloride resembles strychnine in its action. It is **administered** usually as Liquor Strychninæ Hydrochloridi in mixture form, this solution being best prescribed in acid mixtures. The solution may be used for hypodermic injection, but Injectio Strychninæ, which is prepared without alcohol, is preferable. Strychnine hydrochloride is **incompatible** with alkalis and their carbonates, aromatic spirit of ammonia, solution of sodium arsenate, alkaline arsenical solution and iodides. When more than 8 minims of a 1 per cent. solution to 1 fluid ounce of water is prescribed with alkalis, the strychnine is liable to be precipitated. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.002 to 0.008 gramme ($\frac{1}{80}$ to $\frac{1}{8}$ grain).

STRYCHNINÆ ARSENAS.—Strychnine arsenate, $C_{21}H_{22}O_2N_2 \cdot H_2AsO_4 \cdot \frac{1}{2}H_2O$, occurs in the form of small, white, acicular crystals or as a white, crystalline powder. It is soluble in water (about 1 in 14) and in hot water (about 1 in 5). Strychnine arsenate has been used hypodermically in phthisis, and has also been given internally in doses of 0.001 to 0.004 gramme ($\frac{1}{80}$ to $\frac{1}{16}$ grain) in bronchial asthma and emphysema.

STRYCHNINÆ FORMAS.—Strychnine formate, $C_{21}H_{22}O_2N_2 \cdot H \cdot COOH$, occurs in the form of a white, crystalline powder composed of small, acicular crystals. It is soluble in water (about 1 in 5) and in alcohol. Strychnine formate is used as a nerve stimulant and muscular tonic with other formates in the preparation of compound syrups and elixirs. It has been administered hypodermically in doses of 0.001 gramme ($\frac{1}{80}$ grain).

Preparations

Extractum Malti Liquidum cum Quinina et Strychnina, B.P.C.—(Ext. Malt. Liq. c. Quinin. et Strych.)—Liquid Extract of Malt with Quinine and Strychnine. 4 fluid drachms contains about $\frac{1}{2}$ grain of quinine hydrochloride and $\frac{1}{16}$ grain of strychnine hydrochloride, in liquid extract of malt. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Injectio Strychninæ, B.P.C.—(Inj. Strych.)—Injection of Strychnine. It contains 0.75 per cent. w/v of strychnine hydrochloride; 0.6 millilitre contains 0.0045 gramme, and 5 minims contain about $\frac{1}{30}$ grain, of strychnine hydrochloride. Dose.—0.3 to 0.6 millilitre (5 to 10 minims), by subcutaneous injection.

This injection was included in the British Pharmacopœia, 1914, under the name of Injunctio Strychninæ Hypodermica.

Liquor Quininae et Strychninae, B.P.C.—(Liq. Quinin. et Strych.)—Solution of Quinine and Strychnine. It contains quinine sulphate equivalent to from 8.51 to 9.01 per cent. w/v of anhydrous quinine, and strychnine hydrochloride equivalent to from 0.186 to 0.206 per cent. w/v of strychnine, with hypophosphorous acid, glycerin and water. A syrup differing from Syrupus Ferri Phosphatis cum Quinina et Strychnina B.P. only in the presence of 0.75 per cent. v/v of hypophosphorous acid may be made by mixing 1 fluid ounce of this solution, 1 fluid ounce of solution of ferrous phosphate, $\frac{1}{2}$ fluid ounce of glycerin and 1 fluid ounce of distilled water with sufficient syrup to produce 8 fluid ounces.

Liquor Strychninae Hydrochloridi, B.P.—(Liq. Strych. Hydrochlor.)—Solution of Strychnine Hydrochloride. It contains 1 per cent. w/v of strychnine hydrochloride (limits, 0.95 to 1.05) in alcohol (90 per cent.) and distilled water; 0.8 millilitre contains 0.008 gramme, and 12 minims contains about $\frac{1}{4}$ grain, of strychnine hydrochloride. Dose.—0.2 to 0.8 millilitre (3 to 12 minims).

Pilulae Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Pil. Ferr. Phosph. c. Quinin. et Strych.)—Iron Phosphate Pills with Quinine and Strychnine. *Syn.*—Pilulae Trium Phosphatum; Easton's Pills; Pilulae Ferri et Quininae et Strychninae Phosphatum. Each pill contains $1\frac{1}{2}$ grains of saccharated iron phosphate, about $\frac{1}{2}$ grain of quinine sulphate and $\frac{1}{16}$ grain of strychnine hydrochloride, and is approximately equivalent to $\frac{1}{2}$ fluid drachm of syrup of ferrous phosphate with quinine and strychnine. Dose.—1 or 2 pills.

Syrupus Ferri Phosphatis cum Quinina et Strychnina, B.P.—(Syr. Ferr. Phosph. c. Quinin. et Strych.)—Syrup of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Easton's Syrup. It contains iron equivalent to 1.8 per cent. w/v of anhydrous ferrous phosphate, $\text{Fe}_3(\text{PO}_4)_2$ (limits, 1.62 to 1.98), 1.09 per cent. w/v of anhydrous quinine (limits, 1.04 to 1.2), and 0.0246 per cent. w/v of strychnine (limits, 0.022 to 0.027), with syrup, glycerin and distilled water. 4 millilitres contains the equivalent of 0.072 gramme of anhydrous ferrous phosphate or about 0.034 gramme of iron, about 0.059 gramme of quinine sulphate and about 0.0012 gramme of strychnine hydrochloride; 1 fluid drachm contains the equivalent of about 1 grain of anhydrous ferrous phosphate or about $\frac{1}{2}$ grain of iron, about $\frac{1}{2}$ grain of quinine sulphate and about $\frac{1}{16}$ grain of strychnine hydrochloride. The proportion of strychnine is approximately one half the proportion of strychnine contained in the corresponding preparation of the British Pharmacopœia, 1914. It should be stored in completely-filled, well-closed containers and protected from light. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tabellae Ferri Phosphatis cum Quinina et Strychnina, B.P.C.—(Tab. Ferr. Phosph. c. Quinin. et Strych.)—Tablets of Ferrous Phosphate with Quinine and Strychnine. *Syn.*—Tabellae Trium Phosphatum; Easton's Tablets; Tabellae Eastonii; Tabellae Ferri et Quininae et Strychninae Phosphatum. Each tablet contains about $2\frac{1}{2}$ grains of saccharated iron phosphate, $\frac{1}{2}$ grain of quinine sulphate, and about $\frac{1}{16}$ grain of strychnine hydrochloride, and is approximately equivalent to 1 fluid drachm of syrup of ferrous phosphate, with quinine and strychnine. Dose.—1 tablet.

STRYCHNINÆ NITRAS

(Strych. Nit.)

Strychnine Nitrate

Strychnine nitrate may be prepared by dissolving strychnine in nitric acid and crystallising from a neutral solution. It occurs in colourless, glistening needles which are odourless and have an intensely bitter taste. When heated, the salt decomposes without melting. Its aqueous solutions are neutral to methyl red and are lævorotatory.

Soluble in water (1 in 60), alcohol (1 in 120), glycerin and chloroform.

Standard.—Strychnine nitrate leaves not more than 0.1 per cent. of ash. Dissolve 0.2 gramme in 5 millilitres of hot water, and add 0.5 millilitre of barium chloride solution; the liquid remains clear on boiling (limit of sulphate). It complies with the limit test for brucine in Strychnina.

Action and Uses.—Strychnine nitrate is used for similar purposes to the hydrochloride. An aqueous solution (1 in 100) is **administered** as a hypodermic injection. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.002 to 0.008 gramme ($\frac{1}{82}$ to $\frac{1}{8}$ grain).

STRYCHNINÆ SULPHAS

(Strych. Sulph.)

Strychnine Sulphate

Strychnine sulphate may be prepared by adding powdered strychnine, in slight excess, to warm dilute sulphuric acid, filtering the solution, concentrating and crystallising. It occurs in colourless, odourless crystals or as a white, crystalline powder, and has an intensely bitter taste. The salt loses its water of crystallisation when heated at 100° and melts at about 200°. Its aqueous solution is neutral to methyl red and is lævorotatory.

Soluble in water (1 in about 50) and alcohol (1 in 135); slightly soluble in chloroform; insoluble in ether.

Standard.—Strychnine sulphate loses, on drying at 100°, not less than 9 per cent. and not more than 11 per cent. of its weight. Ash, not more than 0.1 per cent. It complies with the limit test for brucine in Strychnina.

Action and Uses.—Strychnine sulphate is used for similar purposes to the hydrochloride. An aqueous solution is **administered** as a

hypodermic injection. Solutions for **injection** may be sterilised by heating in an autoclave, by tyndallisation, or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.002 to 0.008 gramme ($\frac{1}{80}$ to $\frac{1}{8}$ grain).

STYRAX

(Styr.)

Storax

Synonyms—Styrax Præparatus; Prepared Storax.

Storax is the purified balsam obtained from the trunk of *Liquidambar orientalis* Mill. (Fam. Hamamelidaceæ), a tree indigenous to the South-West of Asiatic Turkey. The secretion of the crude balsam, which is not a normal production of the tree, is induced by wounding the bark. The injury thus inflicted on the cambium results in the formation of numerous oleo-resin ducts in which the balsam is secreted and from which it is discharged into the wounded bark. The latter is removed, and the balsam separated by pressing, boiling with water, again pressing, and finally separating the aqueous layer. Thus obtained it forms an opaque, greyish, viscid liquid which on standing separates into a supernatant aqueous liquid and a dark brown oleo-resinous layer; it contains about 20 to 30 per cent. of water together with fragments of bark, etc. From these it is purified by solution in alcohol, filtration and evaporation.

Storax occurs as a brown, viscous liquid which is transparent in thin layers and has an agreeable balsamic odour and taste. When warmed with an aqueous solution of potassium chromate and sulphuric acid, the odour of benzaldehyde is evolved. Storax consists of a resin mixed with an oily liquid. The former consists of storesinol partly free and partly combined with cinnamic acid. The oily liquid contains styrol, vanillin and free cinnamic acid, together with its ethyl, phenyl-propyl and cinnamyl esters.

Soluble in alcohol (90 per cent.), ether, carbon disulphide, chloroform and glacial acetic acid.

Standard, B.P.—Storax contains not less than 30 per cent. of total balsamic acids, calculated on the substance dried on a water-bath for one hour. Loss on drying in a thin layer on a water-bath for one hour, not more than 5 per cent. Acid value, 55 to 90; ester value, 100 to 133; saponification value, 170 to 200, all being calculated on the substance dried on a water-bath for one hour.

Action and Uses.—Storax closely resembles balsam of Peru in its action. An ointment prepared with benzoinated lard (1 in 4) is used as a parasiticide in scabies and other parasitic skin affections.

Dose.—0.6 to 2 grammes (10 to 30 minims).

SUCCUS AURANTII

(Succ. Aurant.)

Orange Juice

Orange juice is the expressed juice of the sweet orange, *Citrus sinensis* (Linn.) Osbeck. It occurs as a turbid, yellow liquid with the characteristic odour and taste of fresh oranges. It contains the antiscorbutic vitamin C. Orange juice may be concentrated *in vacuo* to about one-seventh of its volume without appreciable loss of vitamin C. It is in this form, with or without the addition of sugar or partial removal of the citric acid, that it is most frequently found in commerce. During concentration it loses most of the orange odour and flavour. Such concentrates retain their antiscorbutic activity for a considerable length of time. The assay for vitamin C potency of concentrated orange juice is conducted by a method described for vitamin C concentrates, the unit being the unit of antiscorbutic vitamin C recommended by the Permanent Commission on Biological Standardisation of the League of Nations.

Standard.—Orange juice complies with the Public Health (Preservatives in Food) Regulations, when it contains either not more than 350 parts per million of sulphur dioxide, or not more than 600 parts per million of benzoic acid, and contains no other preservative.

Action and Uses.—Orange juice is used as an antiscorbutic. The protective dose, to replace fresh fruit and vegetables in the diet, is about four ounces daily. The characters and uses of vitamin C are described under *Succus Limonis*.

SUCCUS LIMONIS

(Succ. Limon.)

Lemon Juice

Lemon juice is the expressed juice of the ripe fruit of *Citrus Limonia* Osbeck. It occurs as a slightly turbid, yellow liquid, with a sharply acid taste and an odour of fresh lemons. It may be preserved by the addition of 10 per cent. of alcohol. Lemon juice contains the water-soluble vitamin C. It may be concentrated *in vacuo* to about one-seventh of its volume without appreciable loss of vitamin; in this form, with or without the addition of sugar or partial removal of the citric acid, it is also met with in commerce. The assay for vitamin C potency of lemon juices is conducted by a method described for vitamin C concentrates, the unit being the unit of antiscorbutic vitamin C recommended by the Permanent Commission on Biological Standardisation of the League of Nations.

Standard.—Lemon juice contains not less than 7 per cent. and not more than 9 per cent. w/v of acid, calculated as citric acid, $C_6H_8O_7 \cdot H_2O$.

Specific gravity, 1.030 to 1.045. Ash, not more than 0.5 per cent. w/v. It complies with the Public Health (Preservatives in Food) Regulations, when it contains either not more than 350 parts per million of sulphur dioxide, or not more than 600 parts per million of benzoic acid, and contains no other preservative.

Assay.—Titrate 20 millilitres with N/1 sodium hydroxide, using phenolphthalein as indicator; each millilitre of N/1 sodium hydroxide is equivalent to 0.07003 gramme of $C_6H_8O_7 \cdot H_2O$.

Action and Uses.—Lemon juice is employed as a means of administering vitamin C for the prevention or treatment of scurvy. Vitamin C in the form of orange juice or lemon juice is regarded as a necessary adjunct to the diet in infant feeding, owing to the paucity of vitamin C in milk and the ease with which it is destroyed on heating. Lemon juice well diluted is used as a cooling and refreshing beverage in febrile conditions. It may also be given in effervescence with alkali bicarbonates as an antacid drink, and for the sedative effect on the stomach of the evolved carbon dioxide.

VITAMIN C CONCENTRATES.—Vitamin C is present in the juice of lemon, orange, grape fruit, and some other fruit juices, in fresh green vegetables and in the germinating seeds of pulses. Decitrated orange and lemon juices are convenient starting points in making concentrates of vitamin C. When concentrated to one-tenth of their volume, they keep well when acidified by the addition of 7 grammes of citric acid per litre and stored in the dark in air-free containers. The activity of decitrated lemon juice can be increased by fermentation with yeast in an atmosphere of carbon dioxide. Concentration of vitamin C from lemon juice may be effected by precipitating the organic acids by an excess of calcium carbonate. After the mixture has stood for one hour, the liquid is filtered through a Buchner funnel, and a saturated solution of normal lead acetate added. The quantity of lead acetate must be such that the final preparation has a reducing power to 0.02 per cent. solution of phenolindophenol of not less than 6 millilitres for an equivalent of 5 millilitres of the original decitrated juice. After immediate filtration, or separation by means of a centrifuge, the liquid is adjusted to pH 7.2 to 7.4 by addition of 6 per cent. solution of ammonia. The precipitate, which contains the vitamin, is removed by means of a centrifuge and dissolved in 10 per cent. acetic acid. The lead is removed by addition of saturated magnesium sulphate solution and 2 volumes of alcohol. After filtration, the solution is concentrated to a small volume to remove the greater part of the acetic acid.

In the absence of the water-soluble vitamin C from the diet, scurvy develops in human beings in about four months, the principal symptoms being sore and bleeding gums, diarrhoea, œdema and sub-periosteal hæmorrhage. Some cases of purpura hæmorrhagica are probably due to a deficiency of vitamin C, for it is found that when the supply of this vitamin is inadequate, changes occur in the endothelium of the blood vessels, with escape of red blood cells into the tissues. Chronic hypertrophy of the gums occurring in children may likewise be due to a deficiency of vitamin C. Experimental scurvy in guinea-pigs fed upon a diet free from vitamin C commences in about three weeks, after which a decline in weight sets in and death ensues within six weeks. The histological changes at the rib junction are diagnostic, varying from slight disarrangement in incipient scurvy to complete breakdown at the junction of cartilage cells and bony trabeculae. The earliest recognisable symptom of scurvy is degeneration of the pulp and dentine of the teeth. The nerve cells, blood vessels and odontoblastic cells are converted into a fibroid mass without any trace of cellular organisation.

The biological assay for vitamin C may be carried out by feeding guinea pigs on a diet complete in all respects except in its content of vitamin C. To this diet is added various proportions of the substance under investigation, and the least

amount of the substance necessary to protect the animal from contracting scurvy is taken as the minimum protective dose. The length of time required for this assay varies from one to three months. A more rapid method is to follow the incidence of scurvy by microscopic examination of sections of the roots of the lower incisor teeth of the guinea pig. The advantages of this method of assay are the shorter time required for the test and the greater accuracy in fixing the fully protective dose. The dose required for complete protection, as judged by this method, is about twice that required to prevent the macroscopic lesions of scurvy. The antiscorbutic potency of the preparation under test is determined in terms of the dose of a standard antiscorbutic substance, which would afford the same degree of protection against scurvy. The unit of the antiscorbutic vitamin C recommended by the Permanent Commission on Biological Standardisation of the League of Nations is the vitamin C activity of 0.1 millilitre of fresh lemon juice. This is about one-tenth of the daily dose necessary to prevent the development of macroscopic scorbutic lesions in a young guinea pig maintained on a scurvy-producing diet. The fresh lemon juice may be decitrated by filtration through muslin and adding an excess of calcium carbonate until effervescence ceases; after standing for one hour, the mixture is filtered, and the juice, which should have a pH of about 6, should be administered to the experimental animals within two hours of filtration.

Vitamin C is soluble in water, alcohol and methyl alcohol; insoluble in butyl alcohol and light petroleum. It is sensitive to oxidising agents and to air. Inactivation takes place rapidly at room temperature in alkaline solution in the presence of air, but not in the absence of air. At pH 12.5 decitrated lemon juice loses 80 per cent. of its potency on exposure to air for thirty minutes, and all its potency in three hours. When preserved anaerobically, it does not appreciably decrease in potency during twenty-four hours. Even in the absence of all preservatives, comparatively little change occurs in lemon juice kept at 0° for several months. It does not deteriorate in eighteen months at room temperature in the presence of a small proportion of oil of lemon. The zone of optimal stability at ordinary temperatures is in the neighbourhood of the natural acidity of the juice (pH 2.2) and natural juice can be kept without loss of potency for as long as fourteen months at room temperature without any addition, although it becomes heavily infected with mould and yeast. Conditions which preserve sterility tend to cause deterioration of antiscorbutic potency. Orange juice retains its antiscorbutic potency for eighteen months at room temperature in presence of a small proportion of oil of orange, but at 7° it loses its activity.

Vitamin C is believed to be identical with ascorbic acid, $C_6H_8O_6$, which has been obtained from the cortex of the suprarenal gland and also from paprika, the fruit of a Hungarian variety of *Capsicum annuum*. The antiscorbutic potency of suprarenal cortex is about three times that of orange juice, and is proportional to its content of ascorbic acid. Ascorbic acid, in doses of 1 milligram daily, protects guinea pigs from scurvy. It exerts a marked reducing action on 2:6-dichlorophenolindophenol, and this reaction has been made the basis of a chemical method of assay for antiscorbutic potency. Results by this method are closely in agreement with those obtained biologically, but the test is apparently not truly specific for vitamin C.

SUCROSUM

(Sucros.)

Sucrose

Synonyms—Saccharum Purificatum; Refined Sugar.

Sucrose may be obtained from the juice of the sugar cane, *Saccharum officinarum* Linn. (Fam. Gramineæ), or of the sugar beet, *Beta vulgaris* var. *Rapa* Dumort. (Fam. Chenopodiaceæ). It is extracted from the

sugar cane by boiling the neutralised expressed juice with milk of lime, and evaporating the filtered liquid under reduced pressure. The crude sugar thus obtained is decolourised with charcoal and recrystallised. Sucrose is obtained from the sugar beet by allowing the non-colloidal materials to diffuse from the cells into hot water, the resulting solution being then treated as described above. In both cases the mother liquors contain a considerable quantity of sugar which is separated as the sparingly soluble double compound of sucrose with barium or strontium hydroxide. Occasionally the yellowish tinge of imperfectly purified sugar is masked by the addition of a blue dye; when ultramarine is used, such sugars are liable to produce unpleasant odours when used in the preparation of acid syrups and should not be used for pharmaceutical purposes.

Sucrose occurs in odourless, colourless, crystals or crystalline masses, having a sweet taste. When heated, it fuses at about 160° and does not crystallise on cooling; at higher temperatures it becomes black and froths, forming a bulky carbonaceous residue with a bitter taste. Sucrose does not reduce Fehling's solution. The aqueous solution is clear, colourless and odourless, and is dextrorotatory; when boiled with dilute acids, the sucrose is hydrolysed into equimolecular proportions of lævulose and dextrose, or "invert sugar;" the solution is then lævorotatory and, after neutralisation, readily reduces Fehling's solution. The rate of hydrolysis is very much more rapid than that of any other disaccharide.

Soluble in water (1 in 0.5) and alcohol (90 per cent.) (about 1 in 60).

Standard, B.P.—Sucrose has a specific rotation in 10 per cent. w/v aqueous solution of not less than $+66^{\circ}$ and not more than $+66.7^{\circ}$. Ash, not more than 0.05 per cent. Arsenic limit, 1 part per million. Lead limit, 2 parts per million. It complies also with a test for neutrality, with a test for absence of ultramarine, and with limit tests for reducing sugars and for barium and strontium.

Action and Uses.—Sucrose is employed in pharmacy chiefly as a sweetening agent, and as a demulcent and preservative. In large quantities sucrose irritates the stomach and bowels and exerts a mild aperient action. Weak solutions of sucrose are prone to ferment, but saturated solutions may be preserved indefinitely, the osmotic conditions preventing the growth of bacteria and fungi. The use of sucrose in large quantities is recommended in such wasting diseases as phthisis and cancer. Intravenous injections of sucrose in cases of cardiac failure are stated to exert a marked recuperative effect. Solutions of sucrose dissolve calcium hydroxide freely, forming a calcium saccharate. The syrups are used as flavouring agents and as permanent solutions of active medicinal substances.

SACCHARUM USTUM.—Burnt sugar, or caramel, may be prepared by heating sucrose, with occasional stirring, at about 180° to 200° until a black, viscid mass is formed. It is then mixed with sufficient hot water to produce a liquid of specific gravity 1.4, and strained. Burnt sugar is used as a colouring agent; it is precipitated by alcohol.

THERIACA.—Treacle is the uncrystallisable residue from the refining of cane sugar. It occurs as a thick, brown, sweet, fermentable syrup, free from empyreumatic odour or taste, and does not crystallise on standing.

Preparations

Liquor Sacchari Usti, B.P.C.—(Liq Sacch Ust)—Solution of Burnt Sugar. Burnt sugar and chloroform water, equal parts.

Syrupus, B.P.—(Syr)—Syrup. Sucrose, 66.7 per cent w/w, dissolved in water. Specific gravity, 1.320 to 1.332. Optical rotation, +56° to +59°.

SULPHARSPHENAMINA

(Sulpharsphenamin.)

Sulpharsphenamine

Synonym—Sulpharsenobenzene.

Sulpharsphenamine consists mainly of disodium 3 : 3'-diamino-4 : 4'-dihydroxyarsenobenzene - N : N' - dimethylenedisulphite, $(\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_2\text{Na})(\text{OH})\text{C}_6\text{H}_3\text{As}:\text{AsC}_6\text{H}_3(\text{OH})(\text{NH}\cdot\text{CH}_2\cdot\text{O}\cdot\text{SO}_2\text{Na})$. This compound is the disodium salt of an acid differing from the principal constituent of arsphenamine in the replacement of one hydrogen atom in each of the two amino groups by a methylenedisulphonic group, the replacement being effected by treating the dihydrochloride of arsphenamine with formaldehyde and sodium acid sulphite.

Sulpharsphenamine occurs as a dry, yellow powder, freely mobile in contact with glass surfaces and without odour, except that due to traces of ether or alcohol. It is distributed in sealed glass phials from which the air has been evacuated or replaced by an inert gas. It contains, when determined by an approved method, not less than 18 per cent. and not more than 21 per cent. of As. The proportion of arsenic may be determined by the method given under Sodii Arsenonas. The aqueous solution decolourises solution of iodine. It may be distinguished from neoarsphenamine by the absence of a precipitate on the addition of 1.5 millilitres of dilute hydrochloric acid to a solution of 0.5 gramme in 1.5 millilitres of water, but a yellow precipitate is produced in a few minutes on mixing a 10 per cent. w/v aqueous solution with five times its volume of dilute hydrochloric acid; when the acidified aqueous solution is boiled, sulphur dioxide is evolved. It may also be distinguished from neoarsphenamine by mixing a 10 per cent. w/v aqueous solution with an equal volume of 0.01 per cent. w/v aqueous solution of indigo carmine and maintaining the mixture at 50° for five minutes; the blue colour is not discharged. Sulpharsphenamine evolves formaldehyde when distilled with phosphoric acid as described under Neoarsphenamina. Sulpharsphenamine should be **stored** at a temperature below 15°. If it has become darker in colour, it should not be used.

Soluble in water; insoluble in alcohol (95 per cent.) and ether.

Standard, B.P.—Sulpharsphenamine is controlled by regulations made under the Therapeutic Substances Act, 1925. The standard preparation for Great Britain and Northern Ireland is a quantity of sulpharsphenamine kept in the National Institute for Medical Research, London. It complies with biological tests, carried out in an institution or laboratory approved by the licensing authority, for maximum toxicity and therapeutic potency. When 0·6 gramme of the powder is added to 1 millilitre of water, it dissolves rapidly and completely, forming a clear yellow solution free from suspended particles. No precipitate is produced on shaking a 10 per cent. w/v aqueous solution with an equal volume of N/1 sodium carbonate (absence of arsphenamine). The product in sealed phials, kept at a temperature of 56° for not less than twenty-four hours, retains its colour, physical properties and solubility.

Action and Uses.—Sulpharsphenamine possesses the spirochætidal action of the arsphenamines. It has the advantage of being less toxic than arsphenamine and is the drug of choice for intramuscular injection because no local pain is produced. A further point of great importance is that, experimentally, it has proved more efficient in destroying trypanosomes introduced into the subarachnoid space, an observation which indicates its value in syphilitic affections of the central nervous system. For infants with congenital syphilis the intramuscular route is commonly employed, the dose being gauged by the weight and general condition, although acetarsol by mouth is often considered more satisfactory. Sulpharsphenamine which has become darker in colour should not be used. Solutions for **injection** may be prepared by dissolving the contents of a sealed container in the required quantity of sterile, freshly distilled water and should be used immediately.

Dose.—0·1 to 0·6 gramme (1½ to 10 grains), by subcutaneous or intramuscular injection.

SULPHONAL

(Sulphonal)

Sulphonal

Sulphonal is diethylsulphonedimethylmethane, $(\text{CH}_3)_2\text{C}(\text{SO}_2\cdot\text{C}_2\text{H}_5)_2$, and may be prepared by passing hydrogen sulphide into a mixture of anhydrous acetone and anhydrous mercaptan, whereby mercaptol, $(\text{CH}_3)_2\text{C}(\text{SC}_2\text{H}_5)_2$, is obtained as an oily liquid with a disagreeable odour; it is purified by washing with water and dilute sodium hydroxide solution and is then oxidised with a solution of potassium permanganate. The resulting sulphonal is purified by recrystallisation from water or alcohol.

Sulphonal occurs in colourless, odourless and almost tasteless, prismatic crystals or as a white powder; it is permanent in air. Sulphonal is a very stable body and is scarcely affected by acids or alkalis even on boiling, or by oxidising agents. It dissolves in sulphuric acid and is reprecipitated unchanged from the solution on diluting with water. When heated with carbon, mercaptan is produced and may be recognised by its unpleasant odour. Heated with reduced iron, it evolves a garlic-like odour and leaves a residue containing ferrous sulphide which may be recognised by adding hydrochloric acid, when hydrogen sulphide is evolved. Heated with a few drops of sulphuric acid and a trace of phenol, it becomes emerald-green in colour and gives off a strong sulphurous odour. Heated with anhydrous sodium acetate, hydrogen sulphide is evolved. When fused with three times its weight of potassium hydroxide, it becomes yellow, then red, and on diluting with water, a blue colouration results which, on adding hydrochloric acid, turns a transient violet with separation of sulphur.

Soluble in water (1 in 450), boiling water (1 in 15), alcohol (90 per cent.) (1 in 80), ether (1 in 90), chloroform (1 in 3), benzene (1 in 11) and light petroleum (about 1 in 1000).

Standard, B.P.—Sulphonal has a melting-point of 125° to 127° . Ash, not more than 0.05 per cent. It complies also with limit tests for free acid and for readily oxidisable substances.

Action and Uses.—Sulphonal is a pure hypnotic, possessing no analgesic properties and acting by virtue of its easy solubility in brain lipid and insolubility in water. It is employed in simple insomnia when pain is absent. It is absorbed very slowly on account of its insolubility, and the dose should, therefore, be administered five or six hours before its hypnotic effect is desired. It is excreted even more slowly, and successive doses may have a cumulative effect and give rise to symptoms of poisoning. The hypnotic effect may also be prolonged, so that there is drowsiness on the day following its administration. Continued use of sulphonal may give rise to hallucinations, gastritis and liver damage, and to the destruction of hæmoglobin in the blood with the appearance of hæmatoporphyrin in the urine, which acquires a cherry-red colour. The urine of patients taking sulphonal has a distinct reducing action on Fehling's solution. The tendency to accumulate and to produce hæmatoporphyrinuria renders this drug one of the most dangerous hypnotics for other than occasional use.

Sulphonal is best **administered** in the form of a mixture, suspended with compound powder of tragacanth; the dose should be added to hot water with or without a little spirit. Taken in this way, its action is more rapid and a smaller dose suffices. It may also be dispensed as a powder to be swallowed with hot water or milk, or it may be enclosed in a cachet. When administered in tablets, they should be broken up or chewed, and swallowed with a draught of hot liquid. In cases of **poisoning** by sulphonal, alkaline liquids aid excretion.

Dose.—0.3 to 1.2 grammes (5 to 20 grains).

SULPHUR PRÆCIPITATUM

(Sulphur. Præcip.)

Precipitated Sulphur

S = 32.06

Synonym—Milk of Sulphur.

Precipitated sulphur may be prepared by boiling sublimed sulphur with calcium hydroxide and water for an hour or so, filtering, and decomposing the resulting complex solution of calcium polysulphides and thiosulphate by means of hydrochloric acid diluted with an equal volume of water and added in a thin stream with constant stirring until only a slight alkalinity remains. The precipitate is washed until the washings are tasteless and free from calcium, and is then dried rapidly at a moderate heat. By allowing the mixture to remain slightly alkaline, any arsenic which may have been present in the sulphur or the acid will remain in solution as a soluble thioarsenite. A mixture of precipitated sulphur and calcium sulphate prepared by precipitation with sulphuric acid is sometimes described as Lac Sulphuris.

Precipitated sulphur occurs as a soft, pale greyish-yellow or greenish-yellow powder, which is tasteless, free from grittiness and from any odour of hydrogen sulphide. It melts at about 115°, forming a yellow, mobile liquid which becomes dark and viscid on heating to about 160°. At higher temperatures, it burns with a blue flame and production of sulphur dioxide. It dissolves in hot aqueous solutions of alkali hydroxides with formation of polysulphides and thiosulphates.

Insoluble in water and alcohol (90 per cent.); almost completely soluble in carbon disulphide, the solution depositing the insoluble variety of sulphur on exposure to light; soluble in benzene, light petroleum, oil of turpentine, ether and chloroform.

Standard, B.P.—Precipitated sulphur leaves on ignition not more than 0.5 per cent. of residue. Examined microscopically, it is seen to consist of grouped amorphous globules without any crystalline particles. Arsenic limit, 5 parts per million. It complies also with a limit test for acidity.

Action and Uses.—When taken internally sulphur is partly absorbed as alkali sulphide from the intestine, the remainder being excreted in the fæces unchanged. Its action is entirely due to the sulphide formed, sulphur itself being an inert substance. It exerts a mild stimulant and antiseptic action in the intestine; it increases peristalsis and relaxes the bowels, producing a soft stool without causing pain or colic. The portion absorbed is excreted as sulphate in the urine; small quantities are also excreted by the lungs and by the skin, giving a disagreeable odour to the breath and perspiration. During excretion, sulphides increase the secretion of the bronchioles and skin.

Precipitated sulphur, mixed with milk, syrup, honey, or treacle, or as Confectio Sulphuris or Trochisci Sulphuris, is given to children for its

mildly laxative properties. It is applied to the skin in acne and other skin affections as *Lotio Sulphuris*. An emulsion of sulphur (*Emulsio Sulphuris*) for injection into sinuses is prepared by mixing precipitated sulphur, 1 part, with glycerin, 3 parts by weight, and 1 per cent. of phenol. Lotions of precipitated sulphur with lead acetate are sometimes employed to darken the colour of grey hair.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

Preparations

Confectio Sennæ et Sulphuris, B.P.C.—(*Conf Senn et Sulphur*)—Confection of Senna and Sulphur Equal parts of the confections of senna and sulphur
Dose—4 to 8 grammes (1 to 2 drachms)

Confectio Sulphuris, B.P.—(*Conf Sulphur*)—Confection of Sulphur Precipitated sulphur, about 40 per cent w/w, and potassium acid tartrate, about 10 per cent w/w, mixed with tragacanth, syrup, tincture of orange and glycerin
Dose—4 to 8 grammes (1 to 2 drachms)

Lotio Sulphuris, B.P.C.—(*Lot Sulphur*)—Sulphur Lotion Precipitated sulphur, about 7 per cent w/v, with glycerin, alcohol (90 per cent), rose water and solution of calcium hydroxide

Trochisci Sulphuris, B.P.C.—(*Troch Sulphur*)—Sulphur Lozenges Each lozenge contains 5 grains of precipitated sulphur

This lozenge, containing 0.3 gramme of precipitated sulphur, was included in the British Pharmacopœia 1914

SULPHUR SUBLIMATUM

(Sulphur. Sublim.)

Sublimed Sulphur

S = 32.06

Synonym—Flowers of Sulphur.

Sublimed sulphur is prepared by sublimation from sulphur which may be obtained from deposits of native sulphur occurring in volcanic districts of Italy and Sicily, but the bulk of the world's supply is derived from deposits in Louisiana where it has probably been formed by the action of bituminous matter and the atmosphere on calcium sulphate. In Sicily, it is extracted from the associated mineral matter by fusion and subsequent distillation. The deposits in Louisiana cannot be mined by ordinary methods owing to the presence of hydrogen sulphide and sulphur dioxide and to the fact that the deposit is covered with a quicksand. The sulphur is therefore extracted by pumping superheated steam into the deposit and raising the molten sulphur to the surface by means of compressed air. It is then allowed to solidify and reduced to powder or sublimed. For pharmaceutical purposes, crushed lump sulphur must not be used; it may be distinguished by its microscopical characters and its almost complete solubility in carbon disulphide.

Sublimed sulphur occurs as a fine, yellow, slightly gritty powder. It is odourless and tasteless when pure, but medicinal sublimed sulphur has a distinctly characteristic odour and a faintly acid taste. On exposure to moist air, it is gradually oxidised with formation of sulphuric acid. It burns with a blue flame and production of sulphur dioxide. Sublimed sulphur melts at about 115° , forming a yellow, mobile liquid; on further heating, it becomes dark and viscid at about 160° and boils at 440° .

Partly **soluble** in carbon disulphide; insoluble in water and alcohol (90 per cent.).

Standard, B.P.—Sublimed sulphur leaves on ignition not more than 0.25 per cent. of residue. Examined microscopically, it is seen to consist chiefly of almost opaque, rounded, amorphous particles or aggregates, occasionally associated with semi-crystalline masses. Arsenic limit, 5 parts per million. It complies also with limit tests for acidity and for matter soluble in carbon disulphide.

Action and Uses.—Sublimed sulphur resembles precipitated sulphur in its general properties and is used as a laxative, often with senna (as in *Pulvis Glycyrrhizæ Compositus*). It is much used in chronic skin diseases, gout, rheumatism and chronic bronchitis. Intramuscular injections of a 1 to 8 per cent. emulsion of sulphur in oil, repeated at intervals of five to six days, have been used to induce pyrexia in the treatment of arthritis and general paralysis. The administration of a full dose of sulphur nightly to patients before and while undergoing mercurial treatment for syphilis is found to prevent mercurial stomatitis.

Sulphur is used externally in the form of ointment and lotion as a mild antiseptic and parasiticide in scabies, acne and other skin diseases. When dusted between the toes, sublimed sulphur destroys the fungus producing epidermomycosis. The fumes of burning sulphur are employed as a disinfectant to prevent the spread of infectious diseases; for this purpose it is moulded into flat, circular cakes which are provided with a wick. From 2 to 4 pounds of sulphur should be burned for each 1000 cubic feet of air space.

Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

SULPHUR LOTUM.—Washed sulphur is prepared by digesting sublimed sulphur with water and solution of ammonia for twenty-four hours, with occasional agitation, after which it is washed with water until the washings are neutral. The washed sulphur is then pressed, thoroughly dried at a moderate heat, and passed through a fine sieve. It occurs as a bright greenish-yellow, tasteless and odourless powder. Unless it has been thoroughly dried after washing, it slowly oxidises and again becomes acid. Dose.—1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).

SULPHUR NIGRUM.—Black sulphur was formerly the grey or mouse-coloured, crude natural sulphur obtained from Sicily, but the name is now applied to the residuum from the subliming pots used in the preparation of flowers of sulphur, or to a mixture of sublimed sulphur and charcoal. It occurs as a dark grey or blackish powder. Black sulphur is used chiefly in veterinary medicine.

Preparations

Confectio Guaiaci Composita, B.P.C.—(Conf. Guaiac. Co.)—Compound Confection of Guaiacum. *Syn.*—Chelsea Pensioner. Guaiacum resin, 1 per cent., rhubarb, 2 per cent., and sublimed sulphur, 14·5 per cent., with potassium acid tartrate, nutmeg and purified honey. Dose.—4 to 8 grammes (1 to 2 drachms).

Tabellæ Guaiaci et Sulphuris, B.P.C.—(Tab. Guaiac. et Sulphur.)—Tablets of Guaiacum and Sulphur. Each tablet contains 3 grains of sublimed sulphur and 3 grains of guaiacum resin. Dose.—1 to 3 tablets.

Unguentum Sulphuris, B.P.—(Ung. Sulphur.)—Ointment of Sulphur. *Syn.*—Sulphur Ointment. Sublimed sulphur, 10 per cent., in simple ointment.

Unguentum Sulphuris Camphoratum, B.P.C.—(Ung. Sulphur. Camph.)—Camphorated Sulphur Ointment. Sublimed sulphur, 2 per cent., with phenol, resorcinol, camphor and solution of coal tar, in lard and white soft paraffin.

Unguentum Sulphuris Compositum, B.P.C.—(Ung. Sulphur. Co.)—Compound Sulphur Ointment. Sublimed sulphur and tar, of each 15 per cent., and calcium carbonate, 10 per cent., in lard and soft soap.

Unguentum Sulphuris et Resorcinolis, B.P.C.—(Ung. Sulphur. et Resorcin.) *Syn.*—Unguentum Sulphuris et Resorcini; Sulphur and Resorcin Ointment. Sulphur and Resorcinol Ointment. Sublimed sulphur, 4·5 per cent., and resorcinol, 3 per cent., in yellow soft paraffin.

SULPHURIS CHLORIDUM

(Sulphur. Chlorid.)

Sulphur Chloride

Synonym—Sulphur Monochloride.

Sulphur chloride is prepared by the direct combination of chlorine with sulphur. It occurs as a reddish-yellow, mobile liquid with a disagreeable, penetrating odour. Specific gravity, about 1·70; boiling-point, about 138°; solidifying-point, about -80°. It readily dissolves sulphur and is slowly decomposed by water, forming hydrochloric acid, sulphurous acid and sulphur. It reacts with carbon disulphide to form carbon tetrachloride and free sulphur, and with ethylene, yielding mustard gas and sulphur.

Soluble in benzene; decomposed by water, alcohol and ether.

Action and Uses.—Sulphur chloride is an ingredient of Unguentum Sulphuris Hypochloritis, which has been used in the treatment of acne, psoriasis and scabies.

Preparation

Unguentum Sulphuris Hypochloritis, B.P.C.—(Ung. Sulphur. Hypochlor.)—Sulphur Hypochlorite Ointment. Sublimed sulphur, 12 per cent., and sulphur chloride, 2 per cent., with oil of bitter almond, in lard.

SULPHURIS IODIDUM

(Sulphur. Iod.)

Sulphur Iodide*Synonym*—Sulphur Subiodide.

Sulphur iodide may be prepared by thoroughly mixing together 4 parts of iodine and 1 part of sulphur and heating the mixture gently until the mass assumes a uniformly dark colour, increasing the temperature until liquefaction ensues, allowing the mass to cool and reducing the sulphur iodide to fragments of a convenient size. It occurs as a greyish-black, crystalline solid with an odour resembling that of iodine. Iodine is evolved when sulphur iodide is boiled with water. It should be **stored** in well-closed containers.

Insoluble in water; soluble in glycerin (1 in 16), and carbon disulphide (1 in 4).

Standard.—Sulphur iodide contains not less than 70 per cent. of I.

Assay.—Triturate about 0.5 gramme, accurately weighed, with 20 millilitres of potassium iodide solution, and titrate the mixture with N/10 sodium thiosulphate, using starch solution as indicator; each millilitre of N/10 sodium thiosulphate solution is equivalent to 0.01269 gramme of I.

Action and Uses.—The action of sulphur iodide is virtually that of iodine; it is employed as Unguentum Sulphuris Iodidi in acne rosacea, and for ringworm, scabies and other parasitic diseases of the skin.

Preparation

Unguentum Sulphuris Iodidi, B.P.C.—(Ung. Sulphur. Iod.)—Sulphur Iodide Ointment. Sulphur iodide, 4 per cent., in glycerin and simple ointment.

SUMBUL

(Sumb.)

Sumbul*Synonyms*—Sumbul Root; Musk Root.

Sumbul consists of the transversely sliced and dried root or rhizome of *Ferula Sumbul* Hook. f. and other species of *Ferula* (Fam. Umbelliferae), plants of considerable size growing in Turkestan.

The drug occurs in more or less cylindrical or tapering pieces which are remarkable on account of their extreme lightness. They vary from about 3 to 10 centimetres in diameter and from 2 to 6 centimetres in thickness, often dividing in the upper part into two or more branches. Externally, they are covered with a thin, tough cork which is dark brown in colour, transversely wrinkled and can be stripped off easily. Pieces of

the rootstock bear encircling scars of fallen leaves which are beset with coarse fibres derived from the fibrovascular strands. Internally, the drug is spongy and coarsely fibrous, yellowish-white in colour, and frequently shows spots of exuded resin; it does not exhibit any well-defined structure. A transverse section of a small rhizome shows a pale bark, within which is a ring of narrow, yellowish, wood bundles; the central portion consists of parenchyma, through which vascular bundles pass in various directions. In large pieces the structure is less distinct. The drug has a bitter taste and a faint, musky odour. It contains a volatile oil, an aromatic resin having a bitter taste, and a yellow, viscid fixed oil; in addition it contains free umbelliferone.

Substitutes.—False sumbul is the root of *Dorema Ammoniacum* D. Don. It has a closer texture and a reddish or yellowish colour. There is reason to suppose that much of the commercial drug is obtained from *Ferula suaveolens* Aitchison and Hemsley. This root resembles that of *Ferula Sumbul*, but is devoid of the characteristic musky odour.

Action and Uses.—Sumbul is occasionally employed as a stimulant and antispasmodic in hysterical conditions, usually with preparations of valerian. It is generally prescribed in the form of tincture which requires the addition of mucilage of acacia to suspend the resin.

Preparation

Tinctura Sumbul, B.P.C.—(Tinct. Sumb.)—Tincture of Sumbul. 1 in 10.
Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SUPRARENALUM

(Supraren.)

Suprarenal

Synonyms—Dry Suprarenal Gland; Suprarenal Siccum; Desiccated Suprarenal.

Suprarenal consists of the clean, dried and powdered suprarenal glands obtained from oxen and other mammals. The suprarenal glands are situated above the kidneys. Each gland consists of two parts, an outer cortex and an inner medulla. From the cortex extract of suprarenal cortex may be prepared; from the medulla adrenaline may be obtained. The fresh gland yields about one-sixth of its weight of suprarenal.

Action and Uses.—Suprarenal has been used in doses of 0.06 to 0.3 gramme (1 to 5 grains) in conjunction with injections of adrenaline for the treatment of Addison's disease, but it is now being replaced by Extractum Suprarenali Corticis. Its mode of action is not understood, except that it replaces the natural secretions of the suprarenal glands, which are deficient in Addison's disease. There is evidence that the suprarenal gland has an intimate connection with sodium metabolism.

SYMPHYTUM

(Symphyt.)

Comfrey*Synonyms*—Symphyti Radix; Comfrey Root.

Comfrey consists of the dried root and rhizome of *Symphytum officinale* Linn. (Fam. Boraginaceæ), a widely distributed perennial herb. It is cultivated in Britain and in the United States of America.

The drug consists mainly of segments of the dried root, and occurs in cylindrical pieces from about 10 to 40 millimetres in length and about 5 to 10 millimetres in diameter. Externally, it is nearly black in colour and exhibits glistening crystals on the surface; it is strongly wrinkled longitudinally. The fracture is short, the fractured surface being greyish-white and horny. The smoothed, transverse surface shows a narrow bark, separated by a dark cambium line from the radiate wood, which is composed of narrow bundles separated by wide medullary rays. It has a mucilaginous taste but is without odour.

Comfrey **contains** allantoin, 0.6 to 0.8 per cent., gum, tannin, resin and a trace of starch.

Action and Uses.—The healing action of comfrey has been attributed to the presence of allantoin, which has acquired some reputation as a cell proliferant. Comfrey has been used as an application to wounds, sores and ulcers of various kinds, a mucilaginous decoction of fresh root, peeled and bruised into a pulp, being applied. A decoction has also been given internally in gastralgia and gastric ulcer.

SYMPHYTI FOLIUM.—Comfrey leaf consists of the dried leaves of *S. officinale*. The leaves are broadly lanceolate, often 20 to 25 centimetres in length. The apex is acute and the margin slightly wavy. The leaves are green or brownish-green in colour and extremely rough, due to the presence of numerous short, stiff hairs. The lower leaves are petiolate, and the upper leaves sessile and decurrent along the stem. The microscopical characters are stomata of the cruciferous type on both surfaces; the numerous thick-walled hairs, frequently one-celled, but sometimes with a short basal cell, very sharply pointed, and many, especially those on the lower surface, strongly curved at the tip in the form of a hook; the small, spherical-headed cystolith hairs with unicellular stalks; the slightly wavy-walled, epidermal cells.

TABACUM

(Tabac.)

Tobacco

Tobacco consists of the leaves obtained from *Nicotiana Tabacum* Linn. (Fam. Solanaceæ), a large herb indigenous to America and cultivated in temperate and subtropical countries. The leaves are collected, allowed to wilt, and are then heaped and covered with mats upon which the moisture given off by the leaves condenses. When this "sweating"

process is completed, the leaves are tied into bundles and packed in heaps. The temperature of the heaps rises rapidly and is kept as near as possible to 50° by turning them. The leaves are finally dried.

The leaves are ovate, ovate-lanceolate, or oblong-ovate, brown, and sometimes exceed 50 centimetres in length. The margin is entire, the apex acute, the surface glandular and hairy, and the texture brittle. The venation is pinnate, the lateral veins anastomosing near the margin, and the base is decurrent. The odour is characteristic and the taste nauseous, bitter and acrid.

The diagnostic **microscopical** characters are the stomata of the cruciferous type; the numerous hairs, some of which are glandular, with unicellular or uniseriate stalks, and others are covering hairs, uniseriate or occasionally branched, with acute terminal cells; the sandy crystals of calcium oxalate.

Tobacco **contains** from 1 to 8 per cent. of nicotine. It also contains small quantities of the following bases: nicotine, nicotene, *isonicotine*, nicotone, nicotelline, pyrrolidine, N-methylpyrrolidine; traces of resin and volatile oil are also present.

Action and Uses.—Tobacco is rarely used in medicine. When tobacco is smoked, the nicotine and other substances are partly decomposed into pyridine, furfural, collidine, hydrocyanic acid, carbon monoxide and other bodies, to which the poisonous effect of tobacco smoke is mainly due. Many explanations of the soothing effect of smoking upon the nervous system have been put forward, but agreement is general only in the statement that it is not entirely due to the action of nicotine. Over-indulgence in smoking gives rise to hoarseness and cough, due to congestion of the throat and air-passages. In more severe cases there is a feeble and intermittent action of the heart, depression of the central nervous system, impaired memory, dimness of vision, loss of colour perception, and tremors. The effect of cigar smoking on those who are not accustomed to it is to constrict blood vessels, increase intestinal movements and raise blood pressure; these effects continue for about twenty minutes, during which time the blood pressure may be raised by from 10 to 40 millimetres of mercury. Collapse then ensues, respiration becomes very feeble, the patient breaks out into a cold sweat, and blood pressure falls by from 30 to 50 millimetres of mercury. These effects are probably due to the stimulant action of the nicotine on nerve cells, followed later by the paralytic effect. Those accustomed to tobacco smoking experience none of these symptoms because their tissues are able to oxidise a certain amount of nicotine. In cigarette smoking, carbon monoxide is formed plentifully and, if inhaled, is absorbed owing to its great affinity for hæmoglobin, so that a smoker of 25 cigarettes a day may have 5 per cent. of his hæmoglobin temporarily thrown out of use.

Preparations of tobacco and crude solutions of nicotine are used as insecticides in horticulture by dusting or spraying, or by vaporisation. In cases of **poisoning** by preparations of tobacco, the treatment described under *Nicotina* should be adopted.

TALCUM PURIFICATUM

(Talc. Pur.)

Purified Talc

Synonyms.—Powdered Talc; Creta Gallica Purificata; Purified French Chalk.

Purified talc is a native magnesium silicate, $Mg_6(Si_2O_5)_4(OH)_4$, purified by boiling with dilute hydrochloric acid, decanting the liquid, washing the residue with water and drying at 110° . It occurs as a very fine, white, tasteless and odourless powder, and sometimes contains a small amount of aluminium silicate. Specific gravity, about 2.2 to 2.8. When rubbed on the skin it imparts a feeling of greasiness.

Insoluble in water and dilute solutions of acids and alkali hydroxides.

Standard.—Purified talc loses, on ignition at a red heat, not more than 1 per cent. of its weight. The solution obtained by boiling 5 grammes with 25 millilitres of water for thirty minutes, replacing any water lost by evaporation, and filtering, adding 5 millilitres of nitric acid, and diluting to 50 millilitres, complies with the limit test for iron (limit of water-soluble iron salts). 5 grammes, boiled with 25 millilitres of water for thirty minutes and filtered, produces a filtrate which is neutral to litmus and which, on evaporation, yields not more than 0.005 gramme of residue. On digesting 2 grammes with 40 millilitres of dilute hydrochloric acid for fifteen minutes, filtering and evaporating the filtrate and igniting, not more than 0.01 gramme of residue remains.

Action and Uses.—Purified talc is used as a dusting powder to allay irritation and prevent chafing from friction; for this purpose it is often mixed with zinc oxide, boric acid, or starch, and suitably perfumed. It is also used as an aid in filtering liquids containing finely divided matter in suspension, as a lubricant to facilitate massage operations, and sometimes as a lubricant in tablet making.

TAMARINDUS

(Tamarind.)

Tamarind

Tamarind consists of the fruits of *Tamarindus indica* Linn. (Fam. Leguminosæ), freed from the brittle outer part of the pericarp and preserved with sugar. The tamarind tree is indigenous to Africa, but is cultivated in India and the West Indies. The pod is about 20 centimetres long and 2 centimetres wide and consists of a rough, brownish, rather thin epicarp, a fleshy mesocarp and a leathery endocarp covering each of the 3 to 6 seeds. From the stalk, down the two margins and the midrib, run strong fibrous vascular strands, with finer lateral branches.

The pods, freed from their epicarps, are preserved by pouring hot cane-sugar syrup on them. Copper vessels must not be used for preparing or storing tamarind.

Tamarind is a dark, reddish-brown, moist, sugary mass, in which are embedded the fibrous strands and the large reddish-brown, glossy seeds which are hard and exendospermous, usually sub-quadrangular in shape (about 15 by 12 by 5 millimetres), and enclosed in the tough endocarp. The taste is pleasantly acid and sweet, and the odour is fragrant and fruity.

Tamarind **contains** tartaric acid, potassium acid tartrate and invert sugar. The total acidity varies from 5 to 8 per cent., calculated as tartaric acid. In addition to these constituents it contains the sugar which has been used in the form of syrup to preserve the pulp.

Substitute.—East Indian tamarind consists of the pulp of the fruit pressed into a firm, black mass, with or without the addition of sugar or salt as a preservative, and containing portions of the epicarp in addition to the seeds and fibres. Its acidity varies from 11 to 13 per cent., calculated as tartaric acid.

Standard, B.P.—Tamarind yields no reactions characteristic of copper.

Action and Uses.—Tamarind is mildly laxative; it is an ingredient of *Confectio Sennæ*.

TARAXACUM

(*Tarax.*)

Taraxacum

Synonyms—*Taraxacum* Root; *Taraxaci* Radix; Dandelion Root.

Taraxacum is the fresh or dried root of *Taraxacum officinale* Wiggers (Fam. Compositæ). It is collected in the autumn.

The fresh root is yellowish-white in colour externally and often 30 centimetres or more in length and 12 to 25 millimetres in diameter. Internally, it is whitish and fleshy, and from the freshly cut surface a bitter, milky juice exudes, which may be observed to arise from concentric rings of tissue; a small yellow wood is found in the centre. The dried root is dark greyish-brown, much shrivelled and wrinkled longitudinally and nearly cylindrical in shape. The upper part passes into a short, vertical rhizome which frequently branches, the summit of each bearing the short remains of leaves, near the insertion of which brownish hairs may be seen. The root breaks with a short fracture, the fractured surface showing a narrow cork, a wide phloem in which are numerous, dark, concentric rings marking the position of laticiferous vessels, and a small, porous, yellow wood. The rhizome shows a small pith, and the yellow wood ring is broken at intervals. The drug has a bitter taste, but is without odour.

Taraxacum **contains** a small quantity of the crystalline, bitter substance, taraxacin, together with choline, resin, the phytosterols, taraxasterol

and homotaraxasterol, various fatty acids and variable quantities of sugar and inulin. In the fresh root the inulin is dissolved in the cell sap, but in the dried root it forms amorphous irregular lumps not readily soluble in cold water. The autumnal root has been found to contain 25 per cent. of inulin, whereas the spring root contained 18 per cent. of lævulin and 17 per cent. of uncrystallisable sugar. The dried root yields to alcohol (20 per cent.) about 40 per cent. of extractive.

Action and Uses.—Taraxacum is used as a bitter in atonic dyspepsia, and as a mild laxative in habitual constipation; it has no action on the liver. It is administered as extract, liquid extract and juice.

Preparations

Extractum Taraxaci, B.P.C.—(Ext. Tarax.)—Extract of Taraxacum. A soft extract prepared from the juice of the fresh drug. Dose.—0·3 to 1 gramme (5 to 15 grains).

This extract was included in the British Pharmacopœia, 1914.

Extractum Taraxaci Liquidum, B.P.C.—(Ext. Tarax. Liq.)—Liquid Extract of Taraxacum. 1 in 1, prepared from the dried root. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Succus Taraxaci, B.P.C.—(Succ. Tarax.)—Juice of Taraxacum. The juice expressed from fresh taraxacum root, mixed with one-third its volume of alcohol (90 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This juice was included in the British Pharmacopœia, 1914.

TARTRAZINA

(Tartrazin.)

Tartrazine

Tartrazine (Colour Index No. 640) is the sodium salt of 4-*p*-sulphobenzeneazo-1-*p*-sulphophenyl-5-hydroxypyrazole-3-carboxylic acid, and may be prepared by the condensation of 2 molecules of phenylhydrazine-*p*-sulphonic acid with 1 molecule of dihydroxytartaric acid. It occurs as an orange-yellow powder and usually contains a large proportion of sodium chloride. The colour of the aqueous solution is unaltered on the addition of hydrochloric acid, becomes orange-yellow with sulphuric acid and reddish-yellow with sodium hydroxide. It is readily reduced by titanous chloride.

Soluble in water yielding a golden-yellow solution; incompletely soluble in alcohol.

Standard.—Tartrazine leaves not more than 80 per cent. of sulphated ash. Arsenic limit, 5 parts per million. Lead limit, 50 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is obtained (limit of zinc).

Uses.—Tartrazine is practically unaffected by acids and alkalis, or by light. It is used for colouring lemonade and lemonade powders, the proportion being such that the product will contain about 2 parts per million. In combination with orange G, as in *Liquor Tartrazinæ Compositus*, it forms a useful substitute for the colouring matter of saffron in medicines and foods. The addition of 5 minims of *Liquor Tartrazinæ Compositus* to each fluid ounce of a colourless liquid imparts a stable, saffron-like colour equivalent to that produced by 25 minims of glycerin of saffron or $12\frac{1}{2}$ minims of freshly prepared tincture of saffron. Tartrazine is also used in the manufacture of photographic light filters and of self-screened photographic emulsions.

Preparation

Liquor Tartrazinæ Compositus, B.P.C.—(*Liq. Tartrazin. Co.*)—Compound Solution of Tartrazine. *Syn.*—*Liquor Flavus*. Tartrazine, 0.75 per cent. w/v, and orange G, 0.25 per cent. w/v, in glycerin and chloroform water.

TEREBENUM

(*Tereben.*)

Terebene

Terebene is a mixture of dipentene and other hydrocarbons obtained by shaking oil of turpentine with sulphuric acid, added in successive small quantities, and distilling the separated product in a brisk current of steam. It occurs as a colourless or very pale yellow liquid, having an agreeable, characteristic odour and an aromatic, terebinthinate taste.

Soluble in alcohol (90 per cent.) (1 in 5); almost insoluble in water; miscible with dehydrated alcohol, ether and chloroform.

Standard, B.P.—Terebene has a specific gravity of 0.862 to 0.870. Optical rotation, -2° to $+2^{\circ}$. Refractive index at 20° , 1.471 to 1.474. It distils between 160° and 190° , leaving only a slight viscous residue; not less than 80 per cent. v/v distils between 165° and 185° . Residue on rapid evaporation in a flat dish on a water-bath, not more than 2 per cent. w/w.

Action and Uses.—Terebene closely resembles oil of turpentine in its properties, but its odour is more agreeable. A few drops sprinkled in the room act as a deodorant. It stimulates secretion by the respiratory mucous membrane during its excretion, and is used as an antiseptic and expectorant either taken internally or as an inhalation; it is more especially prescribed in chronic bronchitis, winter cough and phthisis. When taken internally in large doses it may give rise to albuminuria and hæmaturia. It may be **administered** on sugar or enclosed in gelatin capsules; lozenges and pastilles are also prepared. For ordinary administration in mixture form, an emulsion may be prepared by the

usual process for volatile oils. Terebene is used as an inhalation from an oro-nasal respirator; or a suspension in water (1 in 12) may be made with magnesium carbonate and added to hot water.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

TEREBINTHINA CANADENSIS

(Tereb. Canad.)

Canada Balsam

Synonyms—Canada Turpentine; Balsam of Fir.

Canada balsam is an oleo-resin from the balsam fir, *Abies balsamea* Mill. (Fam. Pinaceæ), indigenous to Canada and the Northern United States of America and collected chiefly in Quebec. The oleo-resin is secreted in schizogenous ducts in the bark and collects in cavities which form blisters on the surface; these are punctured, and the oleo-resin collected.

The oleo-resin forms a pale yellow, viscid liquid, often exhibiting a slight green fluorescence. The odour is agreeable and terebinthinate, and the taste is bitter and acrid. It becomes more viscid on keeping, and dries to a hard, transparent varnish that shows little disposition to crystallise. It solidifies when mixed with about one-sixth of its weight of heavy magnesium oxide and a little water (distinction from other coniferous resins). It is soluble in all proportions of benzene, xylene, chloroform and ether, freely soluble in oil of turpentine, and about 80 per cent. soluble in alcohol (90 per cent.).

Canada balsam **contains** a bitter principle which is soluble in water, but consists essentially of a mixture of about 66 per cent. of resin and about 33 per cent. of volatile oil which consists chiefly of *l*- α -pinene. The resin contains about 20 per cent. of an indifferent resene (canadoresene), 20 per cent. of amorphous canadonic acid, and 60 per cent. of amorphous α - and β -canadolonic acids, with which is associated a trace of crystalline canadolic acid. The specific gravity of canada balsam is about 0.987 to 0.994; optical rotation, $+1^{\circ}$ to $+4^{\circ}$; refractive index at 20° , 1.520 to 1.523; acid value, 80 to 90.

Substitute.—Oregon balsam is obtained from the Douglas fir, *Pseudotsuga taxifolia* (Lamb.) Britton, and can be distinguished by its failure to respond to the magnesium oxide test.

Standard.—Canada balsam remains clear when cooled to 10° (absence of excess of moisture).

Action and Uses.—Canada balsam is not given internally. It is used in microscopy as a mounting medium. For this purpose the balsam is warmed in an open dish until a portion of the mass, transferred to a slab, sets to a brittle solid. It is then dissolved in an equal quantity of xylene or other suitable solvent. Such a solution forms a

non-crystallising mounting medium, having a refractive index approximating to that of ordinary glass and therefore involving a minimum dispersion of light.

TERPINI HYDRAS

(Terpin. Hydr.)

Terpin Hydrate

Synonym—Terpene Hydrate.

Terpin hydrate, $\text{C}_{10}\text{H}_{18}(\text{OH})_2 \cdot \text{H}_2\text{O}$, is the hydrate of terpin, $\text{C}_{10}\text{H}_{18}(\text{OH})_2$, and may be prepared by the action of nitric acid on a mixture of alcohol and oil of turpentine. It may be purified by recrystallisation from alcohol. Terpin hydrate occurs in the form of colourless, glistening, rhombic prisms or as a crystalline powder having a slightly aromatic odour and a somewhat bitter taste; it is optically inactive. It melts with loss of water of crystallisation; when heated at 100° it sublimes in fine needles, without decomposition. When a few drops of sulphuric acid are added to its hot aqueous solution, the liquid becomes turbid and acquires a very pleasant odour of lilac, due to the formation of terpineol. Terpin hydrate is rendered anhydrous over sulphuric acid, yielding terpin. Terpin melts at 102° to 103° , and sublimes at 258° without decomposition. Terpin hydrate should be stored in a cool place.

Soluble in water (1 in 280), boiling water (1 in 32), alcohol (90 per cent.) (1 in 14), boiling alcohol (1 in 2), alcohol (60 per cent.) (1 in 46), ether (about 1 in 100) and chloroform (1 in 200); slightly soluble in ethereal oils; insoluble in light petroleum.

Standard.—Terpin hydrate melts between 116° and 119° . Ash, not more than 0.05 per cent. It has no odour of oil of turpentine. The hot aqueous 1 per cent. w/v solution is not acid to litmus.

Action and Uses.—The action of terpin hydrate closely resembles that of oil of turpentine. It is used to lessen cough and expectoration in phthisis and chronic bronchitis and for this purpose may be administered in pills massed with glycerin of tragacanth, or as an elixir.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

TERPINEOL.—Terpineol, $\text{C}_{10}\text{H}_{17}\text{OH}$, is a product of the fractional distillation of terpinol, and may be prepared by treating terpin hydrate with 0.1 per cent. sulphuric acid. Terpineol occurs usually as a colourless, viscid liquid, having a strong, pleasant odour of hyacinth and lilac, and a bitter, feebly pungent taste. Specific gravity, about 0.94; boiling-point, about 216° . Optically inactive. It should be stored in well-stoppered, dark-coloured bottles. It is insoluble in water, and soluble in alcohol and ether. Terpineol is used largely in soap-making and perfumery.

TERPINOL.—Terpinol, $\text{C}_{10}\text{H}_{16}$, is a mixture of several terpenes such as terpinene, terpinolene and dipentene, with variable proportions of oxygenated

bodies (terpineol and cineole), prepared by distilling 1 part of terpin hydrate with 5 parts of 10 per cent. sulphuric acid. The colourless or nearly colourless liquid, with a strong odour of hyacinth, passes over between 160° and 220°. It is insoluble in water, and readily soluble in alcohol and ether. Terpinol has been given internally in place of terpin hydrate. It is used in soap-making and perfumery.

Preparations

Elixir Æthylmorphinæ et Terpini, B.P.C.—(Elix. Æthylmorph. et Terpin.)—

Elixir of Ethylmorphine and Terpin. Each fluid drachm contains approximately $\frac{1}{4}$ grain of ethylmorphine hydrochloride and $\frac{1}{16}$ grain of terpin hydrate, with alcohol (90 per cent.), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Diamorphinæ et Pini Compositum, B.P.C.—(Elix. Diamorph. et Pini Co.)—

Compound Elixir of Diamorphine and Pine. Each fluid drachm contains approximately $\frac{1}{16}$ grain of diamorphine hydrochloride and $\frac{1}{16}$ grain of terpin hydrate, with oil of pumilio pine, alcohol (90 per cent.), compound solution of tartrazine, glycerin and sucrose. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Diamorphinæ et Terpini, B.P.C.—(Elix. Diamorph. et Terpin.)—

Elixir of Diamorphine and Terpin. Each fluid drachm contains approximately $\frac{1}{16}$ grain of diamorphine hydrochloride and $\frac{1}{16}$ grain of terpin hydrate, with alcohol (90 per cent.), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Diamorphinæ et Terpini cum Apomorphina, B.P.C.—(Elix. Diamorph.

et Terpin. c. Apomorph.)—Elixir of Diamorphine and Terpin with Apomorphine. Each fluid drachm contains $\frac{1}{16}$ grain of diamorphine hydrochloride and $\frac{1}{16}$ grain of terpin hydrate, with apomorphine hydrochloride, alcohol (90 per cent.), glycerin and syrup of wild cherry. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

TETRACHLORETHYLENUM

(Tetrachlorethylene.)

Tetrachlorethylene

Synonym—Perchlorethylene.

Tetrachlorethylene, $\text{CCl}_2:\text{CCl}_2$, may be prepared by treating pentachlorethane, C_2HCl_5 , with milk of lime. It is a colourless, mobile liquid with an odour somewhat resembling that of carbon tetrachloride.

Insoluble in water; miscible with alcohol, ether and oils.

Standard.—Tetrachlorethylene boils between 117° and 122°. Specific gravity, 1.61 to 1.63. It complies with the limit tests for non-volatile residue, sulphur compounds, free chlorine and ionisable chlorides in Carbonei Tetrachloridum.

Action and Uses.—Tetrachlorethylene is used for the expulsion of hook-worms from man and animals; it is also useful against round-worms in animals. It may be administered in gelatin capsules. For the treatment of ankylostomiasis, it may be given in doses totalling 3, 4 and 5 millilitres on each of three consecutive days. The dose should be divided into portions of 1 millilitre each, given at intervals of one hour, and on the third day, about three hours after taking the last dose, a purge of

sodium sulphate should be administered. For debilitated patients the dose should not be more than 3 millilitres a day. During the treatment patients should be kept at absolute rest, they should avoid alcoholic drinks and take liberal quantities of milk. No serious ill effects have been noted during treatment, although some patients have experienced a transitory sensation of unsteadiness and vertigo immediately after taking the capsules. Although the drug is eliminated by the kidneys, albuminuria has never been noted. Tetrachlorethylene is less toxic than carbon tetrachloride; it does not produce liver damage. It has not been shown to have any action on the liver-fluke. Tetrachlorethylene is also used as a solvent for cellulose acetate in the manufacture of lacquers.

Dose.—1 millilitre (15 minims).

PENTACHLORETHANUM.—Pentachlorethane, $\text{CHCl}_2\cdot\text{CCl}_3$, may be obtained by the catalytic chlorination of trichlorethylene, and occurs as a colourless, non-inflammable, toxic liquid, having a specific gravity of 1.685 to 1.709, and a boiling-point of about 179° . It is used as a solvent in the manufacture of lacquers and varnishes.

TETRACHLORETHANUM.—Tetrachlorethane, $\text{CHCl}_2\cdot\text{CHCl}_2$, or acetylene tetrachloride, is a colourless liquid, having an odour resembling that of chloroform. Specific gravity, about 1.60. Boiling-point, about 146° . Tetrachlorethane is three to four times as toxic as chloroform. It should be used only in enclosed apparatus or in well-ventilated spaces. Toxic effects are shown by abnormal fatigue, nervousness, loss of appetite, nausea and vomiting, and, in severe cases, by jaundice and enlargement of the liver. It is used as a solvent for cellulose acetate, bitumen, waxes, resins, tar, pitch, sulphur and rubber. It is employed as a fumigant for the destruction of "white fly" in greenhouses; for 1000 cubic feet, 10 fluid ounces is allowed to volatilise.

TRICHLORETHYLENUM.—Trichlorethylene, $\text{CHCl}\cdot\text{CCl}_2$, has similar properties to tetrachlorethylene. Specific gravity, about 1.47. Boiling-point, about 88° . Trichlorethylene appears to have some selective action on the sensory endings of the trigeminal nerve and has been used in trigeminal neuralgia. Different individuals show wide differences in susceptibility to its actions; hence the dose necessary to afford relief varies. Therapeutic doses sometimes cause transitory giddiness, palpitation and nausea. It is administered by inhalation, 10 to 20 drops being inhaled from cotton wool. This may be repeated after a little time, but not more than 60 minims should be inhaled within twenty-four hours. Trichlorethylene is irritant, hence it should not be allowed to come into contact with the nose when the vapour is inhaled. Externally, it has been used to destroy body lice, a 1 in 4 solution of trichlorethylene in soft paraffin being rubbed on the affected parts. Trichlorethylene is rather more toxic than chloroform. It is used as a solvent for rubber, bitumen, resins, fats and sulphur, and to reduce the inflammability of lacquers.

THALLII ACETAS

(Thall. Acet.)

Thallium Acetate

$\text{C}_2\text{H}_3\text{O}_2\text{Tl} = 263.4$

Synonym—Thallous Acetate.

Thallium acetate, $\text{CH}_3\cdot\text{COOTl}$, may be prepared by neutralising an aqueous solution of thallous hydroxide with acetic acid. The salt may

be recrystallised from alcohol. It occurs as colourless needles or as a white, crystalline powder, melting at about 131° . When moistened with hydrochloric acid and introduced on a platinum wire into the bunsen flame, it gives a green colour to the flame. Hydrogen sulphide gives with thallous compounds in ammoniacal solution a black precipitate soluble in mineral acids, but insoluble in acetic acid. An aqueous solution of a thallous salt yields a light yellow precipitate with potassium iodide, a light yellow precipitate with platinic chloride, a scarlet precipitate with sodium cobaltinitrite, and a yellow precipitate with potassium chromate solution.

Soluble in water.

Standard.—Thallium acetate contains not less than 98 per cent. of $C_2H_3O_2Tl$. 1 gramme complies with the limit test for chlorides.

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 20 millilitres of hot water, add 5 millilitres of sulphurous acid and warm on a water-bath; cool, add about 0.5 gramme of potassium iodide and allow to stand for twelve hours. Collect the precipitate of thallous iodide, wash with a 1 per cent. w/v potassium iodide solution and then with alcohol, dry at 100° and weigh; 1 gramme of thallous iodide is equivalent to 0.7950 gramme of $C_2H_3O_2Tl$.

Action and Uses.—Thallium acetate is used principally for its action as a depilatory in the treatment of ringworm of the scalp. It must be used with great caution, since if given in other than therapeutic doses it is apt to produce marked toxic symptoms. In therapeutic doses the epilation is confined to the scalp; large doses cause epilation of all parts of the body and produce toxic symptoms such as diarrhoea and vomiting, stomatitis, albuminuria, delirium and collapse. The margin between the dose required for epilation and the toxic dose appears to be extremely small and it is too powerful a drug to be used in routine treatment.

The average dose is 0.008 gramme per kilogram ($\frac{2}{38}$ grain per pound) of body weight, except when there is a marked discrepancy between age and body weight. This dose must not be repeated within a period of three months owing to the cumulative action of the drug and consequent danger of poisoning. Epilation takes place in about a fortnight, and the hair starts to grow again in about the same time. Permanent baldness does not occur. Young children tolerate thallium acetate much better than those past the age of puberty, and it is generally agreed that this treatment should be confined to children under ten years of age. Some authorities recommend its use only for children of four years and under, or where X-rays have proved unsuccessful. Strict attention to dosage is essential and the drug is contra-indicated when there is albuminuria or any general constitutional disease. After puberty severe toxic symptoms are likely to be produced and may cause permanent injury to health. Thallium acetate is best **administered** in sweetened aqueous solution.

In the treatment of **poisoning** by thallium salts the stomach should

be emptied by lavage or by emetics, and a cathartic administered to eliminate unabsorbed material from the gastro-intestinal tract. In acute cases 25 grammes of dextrose should be given intravenously, heat applied to the extremities and caffeine or adrenaline given to overcome shock. Intravenous injection of sodium iodide to convert the toxic soluble thallium salts into the almost insoluble iodides has been suggested; from 0.3 to 1 gramme (5 to 15 grains) may be given daily, increased to 1.6 to 2.6 grammes (25 to 40 grains) or more. Subsequently intravenous injection of sodium thiosulphate in doses of 0.3 to 1 gramme daily for an adult, and proportionate doses for children, may be given to promote the gradual elimination of the thallium in the urine. If too large doses of sodium thiosulphate are given, the thallium may be eliminated too rapidly with a return of toxic symptoms.

THEA

(Thea)

Tea

Tea is prepared from the young leaves and leaf-buds of *Camellia sinensis* (Linn.) O. Ktze. (Fam. Theaceæ), a shrub cultivated in China, Japan, Assam, Ceylon and other tropical countries. The leaf buds, together with two or three of the youngest leaves, are collected, allowed to wilt, and then rolled by hand or machinery until they acquire the characteristic twist. They are then subjected to a process of fermentation, the leaves being allowed to reach a temperature of 35° to 40°, until the colour changes to a yellowish-brown; they are then rolled again, rapidly dried, and graded by sifting. In the production of green tea, the slightly wilted leaves are at once heated in a pan over an open fire; they are then collected and fermented, during which the green colour is more or less retained. The difference in colour is probably due to the destruction by heat of an oxidase (thease) which, in the case of black tea, acts upon the tannin, converting part of it into insoluble oxidation products, hence green tea contains more tannin than black. During the fermentation process, which is common to both black and green tea, changes are induced, resulting in the production of the characteristic aroma and the destruction of a bitter principle. The nature of these changes is rather obscure but they are probably due to enzyme action.

The leaf is usually broadly lanceolate, firm in texture, rather thick, and tapers to a short petiole. The upper surface is glossy, and the under surface, when the leaf is young, is pubescent, and in older leaves nearly glabrous. The serrated margin is slightly inrolled and bears characteristic, shrunken, glandular teeth which readily break off. Old leaves may attain 15 centimetres in length, but those used for the production of tea seldom exceed 5 centimetres.

The diagnostic **microscopical** characters are the occasional thick-walled, tapering, unicellular hairs, often attaining 500 to 700 microns in

length; the lignified, sclerenchymatous, branched idioblasts, especially in the petiole and midrib; the stomata on the under surface only, each stoma being surrounded by three or four tangentially elongated cells; the cluster-crystals of calcium oxalate in the spongy parenchyma. When the powder is heated, a characteristic micro-sublimate of caffeine is obtained.

Tea **contains** 1 to 4 per cent. of caffeine, 7 to 15 per cent. of tannin and a trace of volatile oil; traces of xanthine, hypoxanthine, adenine and theophylline have also been detected. The percentage of caffeine is usually between 3 and 4 per cent.; the commercial value of tea is, however, not determined by this factor alone, but by consideration of the size of the leaf and the taste of the infusion. The total ash varies from about 5 to 6.5 per cent.; the acid-insoluble ash is usually less than 0.5 per cent.

Standard.—Tea yields not less than 3 per cent. of water-soluble ash; alkalinity of the ash, calculated as K_2O , not less than 1.3 per cent.

Tea, in powder (*Pulvis Theæ* : *Pulv. Theæ*), contains the constituents and possesses the diagnostic microscopical characters of *Thea*, and complies with the limits for water-soluble ash and alkalinity of the ash of the unground drug.

Uses.—Tea is used principally as a beverage. It is used in mixtures prepared for smoking or burning in asthma. A strong decoction of tea is used as an antidote in cases of poisoning by alkaloids and heavy metals and as an extemporaneous means of preparing tannic acid solution for use in the treatment of burns.

CATHA.—Catha, or Kat, Kath, Arabian or Abyssinian tea, consists of the dried leaves of *Catha edulis* Forsk. (Fam. Celastraceæ), a small tree growing in Abyssinia and South-Western Arabia. The leaves are about 9 centimetres long and 4 centimetres wide; they are lanceolate or ovate-lanceolate, shortly petiolate, coriaceous and brownish-green; the upper surface is glossy, and the margin serrate. The odour is aromatic, and the taste, aromatic, sweet and astringent. Catha contains the alkaloids, *d*-nor-isoephedrine (cathine), cathidine and cathinine. Other constituents are sugar, tannin and volatile oil. The action of catha may be taken as essentially comparable with that of other vegetable products which are used as "stimulant narcotics." It dilates the pupils and excites the whole of the central nervous system, but precise knowledge as to its mode of action is lacking.

MATE.—Maté, Paraguay tea or Maté Folia, consists of the dried leaves of *Ilex paraguensis* Hook. and other species of *Ilex* (Fam. Aquifoliaceæ), shrubs indigenous to Brazil and Argentina. After collection and drying, the drug is reduced to a coarse powder, which is packed in hide serons or in sacks for transportation. The leaves are shortly petiolate, ovate or oblong-lanceolate, 5 to 15 centimetres long, and the margin is distantly crenate-serrate; the surface is nearly glabrous, pale or dark green in colour, and the texture is coriaceous. The odour is aromatic, and the taste bitterish, astringent and somewhat empyreumatic. The diagnostic microscopical characters are the small, isodiametric, straight-walled cells of the upper epidermis, with a thick, striated cuticle; the lower epidermis with numerous stomata, each of which is surrounded and overhung by four or five cells; the abundant prismatic and cluster-crystals of calcium oxalate, occurring particularly in the cortex of the midrib, which is accompanied by a sheath of lignified, pericyclic fibres. Maté contains from 0.2 to 2 per cent. of caffeine, and about 7 per cent. of tannin. It is used in the form of infusion as a refreshing drink.

THEOBROMATIS SEMEN

(Theobrom. Sem.)

Theobroma Seed*Synonyms*—Cacao Seed; Cocoa Seed.

Theobroma seed consists of the fermented and dried seeds of *Theobroma Cacao* Linn. (Fam. Sterculiaceæ), a native of tropical America and cultivated in most tropical countries. The bulk of the seed is exported from the West Coast of Africa, Ecuador and Brazil.

The seeds are flattened, ovoid, about 22 millimetres long, about 12 millimetres wide and about 6 millimetres thick. The testa is thin, brittle and brownish-red, and is marked with longitudinal veins radiating from the chalaza. The kernel consists of two irregularly folded, brown cotyledons which readily break into small, angular fragments (cocoa nibs), and into the folds of which the narrow endosperm penetrates. They have an agreeable odour when bruised or heated. The taste is at first astringent and bitter and then bland and oily.

The diagnostic **microscopical** characters are the elongated, polygonal cells of the seed coat epidermis, to which is nearly always attached the inner epidermis of the pericarp, the cells of which are narrow and elongated, crossing those of the epidermis at right angles; the large mucilage cells of the hypodermis; the sclerenchymatous layer of the seed coat; the polygonal cells of the cotyledons containing small starch grains; the epidermis of the cotyledons containing granules of brown pigment and bearing somewhat club-shaped, multicellular hairs.

The kernel **contains** about 0.9 to 3 per cent. of theobromine, together with a small amount of caffeine, 40 to 60 per cent. of solid fat, and about 2.5 per cent. of sugars, mainly sucrose and dextrose. The shell contains about 0.4 to 2 per cent. of theobromine and also mucilage.

Uses.—Theobroma seed is used as the source of oil of theobroma and for the preparation of cocoa powder and chocolate.

THEOBROMA PREPARATA.—Cocoa powder, or cocoa essence, is roasted theobroma seed, deprived of its shell, pressed to remove a portion of the fat, and finely ground. Before expression of the fat, the seeds are frequently subjected to a process of "alkalisation" with magnesium carbonate or a solution of sodium, potassium or ammonium carbonate. The powder is often flavoured by the addition of small amounts of vanillin or powdered cinnamon bark. Cocoa powder is a fine powder, varying in colour from light brown to dark reddish-brown, and having a flavour and odour similar to those of theobroma seed but more aromatic; it exhibits the microscopical characters described under theobroma seed. Cocoa powder contains from 20 to 30 per cent. of fat (cocoa butter), 0.05 to 2 per cent. of theobromine, and from 3 to 6 per cent. of moisture. The total ash varies from 4.5 to 7.5 per cent., and the acid-insoluble ash from 0.02 to 0.2 per cent. Cocoa powder is used in the preparation of certain tablets and lozenges, and in the preparation of compound powder of barium sulphate. It is also used as a nutritious beverage taken in hot milk or water.

THEOBROMA SACCHARATA.—Chocolate is roasted theobroma seed, deprived of its shell, finely ground and mixed with powdered sugar and a proportion of cocoa fat, with the addition of a small amount of vanillin or other flavouring

material. After incorporation of the ingredients, the mixture is subjected to hot milling and then poured into metal moulds. Chocolate usually occurs in the form of slabs or bars, which are brittle and break with a smooth, uniform fracture, or in powder; it is of a dark reddish-brown colour, and has a flavour and odour similar to those of theobroma seed but sweeter and more aromatic. Chocolate contains from about 28 to 38 per cent. of fat (cocoa butter), and from about 40 to 60 per cent. of sugar. The ash varies from about 2.5 to 4 per cent. Chocolate powder is used in the preparation of tablets and lozenges. Its agreeable flavour and preservative action also render it useful as a basis for preparing glyceryl trinitrate, erythryl tetranitrate and santonin tablets, and for coating pills.

THEOBROMINA

(Theobrom.)

Theobromine

Theobromine, or 3 : 7-dimethylxanthine, is an alkaloid contained in the seeds of *Theobroma Cacao* Linn. It is said not to be present as theobromine in the unfermented seeds, but to develop during the process of curing by the splitting up of a glycoside, dextrose and cacao-red being the other products. It may be prepared from cocoa husk by extracting with water and lime, neutralising and evaporating the extract, and subsequently purifying the crude theobromine by decolourising with charcoal and recrystallising from boiling water.

Theobromine occurs in the form of an odourless, white, crystalline powder or in rhombic needles, having a neutral reaction and a taste at first, slightly bitter, but gradually becoming more bitter. It sublimes at 290° without decomposition, and behaves both as an acid and as a weak base. When bromine water is added to a solution of theobromine in hydrochloric acid and excess of bromine is driven off, the solution turns blue on the addition of a trace of ferrous sulphate solution and a few drops of ammonia. On evaporating a mixture of theobromine and chlorine water to dryness and then adding ammonia, a purple colour is developed. The alkali hydroxides form salts and the alkaloid is not extracted from alkaline solution by shaking with immiscible solvents. Theobromine is readily and completely converted into caffeine by mixing a solution in a slight excess of sodium or potassium hydroxide with dimethyl sulphate. Neutral solutions are not precipitated by solutions of iodine in potassium iodide, but on the addition of acid a copious precipitate is produced. Neither neutral nor acid solutions are precipitated by potassio-mercuric iodide solution.

Soluble in water (1 in 1000), boiling water (1 in 115), alcohol (1 in 1400) and boiling alcohol (1 in about 260).

Standard.—Theobromine loses, on drying at 100°, not more than 3 per cent. of its weight. Ash, not more than 0.1 per cent. Potassio-mercuric iodide solution produces no cloudiness or precipitate in a 1 in 2000 aqueous solution (limit of other alkaloids). Dissolve 1 gramme in 10 millilitres of water and 5 millilitres of sodium hydroxide

solution and extract with two successive portions of 10 millilitres each of chloroform; filter the chloroform extracts through a dry filter, evaporate and dry at 100°; the residue weighs not more than 0.010 gramme (limit of caffeine). 0.4 gramme dissolves in 10 millilitres of sulphuric acid, the solution being coloured not more than faintly yellow (limit of readily carbonisable substances).

Action and Uses.—Theobromine resembles caffeine in its action, with the difference that, while its effect upon the central nervous system is very much less than that of caffeine, its action on muscle, and on the kidneys and heart is more pronounced. It is used principally for its diuretic effect, rendering the kidney structures more permeable to water. This action is exerted with more certainty and to a greater extent than with caffeine, and the nervous symptoms and cerebral excitement produced by the latter are absent. It is especially useful when there is an accumulation of fluid in the body resulting from cardiac failure, in which case it is often prescribed with digitalis. Although theobromine produces a general rise in blood pressure, the rise is less than that produced by caffeine and its employment in high blood pressure is not contra-indicated. It is sometimes used in angina pectoris and is employed in dropsy of renal or hepatic origin. It is contra-indicated in acute nephritis. In large doses it may cause nausea and loss of appetite.

Theobromine is best **administered** in powders or cachets. A combination of theobromine and phenobarbitone in tablet form, *Tabellæ Phenobarbitoni et Theobrominæ*, is sometimes employed to allay the nervous excitement and insomnia associated with arteriosclerosis and angina pectoris.

Dose.—0.3 to 0.6 gramme (5 to 10 grains).

THEOBROMINA ET SODII ACETAS.—Theobromine and sodium acetate is a mixture of sodium acetate with the sodium derivative of theobromine, and contains about 63 per cent. of theobromine. It occurs as a white, odourless, hygroscopic powder, soluble in water (1 in 2) and in alcohol (90 per cent.) (1 in 200). It is decomposed by acids and is incompatible with sodium bicarbonate, alkaloids and ammonium salts. Theobromine and sodium acetate is used for the same purposes as theobromine. **Dose.**—0.6 to 1 gramme (10 to 15 grains).

Preparation

Tabellæ Phenobarbitoni et Theobrominæ, B.P.C.—(*Tab. Phenobarbiton. et Theobrom.*)—Tablets of Phenobarbitone and Theobromine. Each tablet contains $\frac{1}{2}$ grain of phenobarbitone and 5 grains of theobromine. **Dose.**—1 or 2 tablets.

THEOBROMINA ET SODII SALICYLAS

(*Theobrom. et Sod. Salicyl.*)

Theobromine and Sodium Salicylate

Theobromine and sodium salicylate is a mixture of sodium salicylate and the sodium derivative of theobromine in approximately molecular

proportions. It may be obtained by dissolving 90 parts of theobromine in 100 parts of water containing 20 parts of sodium hydroxide, adding the solution to a solution of 80 parts of sodium salicylate in 75 parts of water, evaporating the mixed solutions rapidly, and drying the product. It occurs as a white, odourless, amorphous powder, having a sweetish, alkaline taste. The aqueous solution is strongly alkaline to phenolphthalein; when acidified with acetic acid and ferric chloride solution is added, a violet colour is produced. When the aqueous solution is neutralised with hydrochloric acid, a white precipitate of theobromine is produced which, when washed and dried, responds to the identity tests described under Theobromina. On ignition, theobromine and sodium salicylate leaves a residue of sodium carbonate. It should be **stored** in well-closed, glass-stoppered bottles and protected from light.

Soluble in water (1 in 1); insoluble in alcohol (90 per cent.), ether and chloroform.

Standard, B.P.—Theobromine and sodium salicylate contains not less than 46 per cent. of $C_7H_8O_2N_4$ (theobromine), not less than 41 per cent. of $C_7H_5O_3Na$ (sodium salicylate), and not more than 6.9 per cent. of Na additional to that contained in the sodium salicylate, all calculated on the substance dried at 110° . Loss on drying at 110° , not more than 5 per cent. Arsenic limit, 2 parts per million. Lead limit, 10 parts per million. A 20 per cent. w/v aqueous solution is clear and colourless or faintly yellow. It complies also with a limit test for caffeine.

Action and Uses.—The properties of theobromine and sodium salicylate resemble those of theobromine. It is used as a diuretic in cardiac dropsy and chronic Bright's disease with œdema; administered with digitalis, its diuretic action is prolonged. It may be pointed out that the use of any diuretic involves greater work for the kidneys; even the increased excretion of water causes the kidneys to absorb more oxygen and excrete more carbonate. Hence it is doubtful how far it is desirable to increase the activity of diseased kidneys. Theobromine and sodium salicylate is best **administered** in solution, cachets or tablets. It is **incompatible** with acids, ammonium salts and sodium bicarbonate.

Dose.—0.6 to 1.2 grammes (10 to 20 grains).

THEOPHYLLINA

(Theophyll.)

Theophylline

Theophylline, or 1:3-dimethylxanthine, is an isomeride of theobromine with which it is found associated in small quantities in tea. It may be isolated from the mother liquors obtained in the separation of theobromine from this source, but is also manufactured by synthesis from

dimethylcarbamide and ethylcyanacetate. It occurs as a white, crystalline powder containing one molecule of water of crystallisation, which can be removed by heating at 100°. It is odourless and has a bitter taste. Theophylline is a weak base, forming salts with acids and soluble derivatives with the alkali metals. It forms insoluble compounds with silver and mercury. 0.01 gramme with 1 millilitre of hydrochloric acid and 0.1 gramme of potassium chlorate, evaporated to dryness in a porcelain dish, leaves a reddish residue which becomes purple when exposed to the vapour of dilute solution of ammonia.

Soluble in water (1 in 160) and alcohol (90 per cent.) (1 in 100); sparingly soluble in ether; readily soluble in solutions of alkali hydroxides.

Standard.—Theophylline melts between 265° and 270°. Loss on drying at 100°, not more than 9.5 per cent. Residue on ignition, not more than 0.1 per cent. A saturated aqueous solution is neutral to litmus. 0.2 gramme dissolves readily and completely in 5 millilitres of sodium hydroxide solution, and in 5 millilitres of dilute solution of ammonia.

Action and Uses.—Theophylline has a more marked diuretic action than theobromine, but is liable to cause digestive disturbance. It is generally **administered** in the form of theophylline and sodium acetate.

Dose.—0.06 to 0.15 gramme (1 to 2½ grains).

THEOPHYLLINA ET SODII ACETAS

(Theophyll. et Sod. Acet.)

Theophylline and Sodium Acetate

Theophylline and sodium acetate may be obtained by mixing an aqueous solution of the sodium derivative of theophylline with an aqueous solution of an equimolecular proportion of sodium acetate, and evaporating the mixture to dryness. It occurs as a white, odourless, crystalline powder, with a bitter taste. The aqueous solution is alkaline to litmus; when neutralised with dilute acetic acid, it yields a white precipitate of theophylline which, when washed and rendered anhydrous by drying at 100°, has a melting-point of 265° to 272°. The separated theophylline responds to the test with hydrochloric acid, potassium chlorate and ammonia vapour described under *Theophyllina*; it may be distinguished from theobromine by its greater solubility in dilute solution of ammonia, forming a clear 4 per cent. w/v solution. When a suspension of theophylline and sodium acetate in alcohol (70 per cent.) is boiled with a few drops of sulphuric acid, the odour of ethyl acetate is evolved.

Soluble in water (1 in 25); insoluble in alcohol (90 per cent.), ether and chloroform.

Standard, B.P.—Theophylline and sodium acetate contains not less than 55 per cent. of anhydrous theophylline, $C_7H_8O_2N_4$. Arsenic limit, 2 parts per million. It complies also with a limit test for caffeine.

Action and Uses.—Theophylline and sodium acetate resembles theobromine in its action, but is a more powerful diuretic and, like theophylline, is more liable than theobromine to cause gastric disturbance. It may be **administered** in solution or in cachets. Theophylline and sodium acetate is **incompatible** with acids, ammonium salts and sodium bicarbonate.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

THIOSINAMINA

(Thiosinam.)

Thiosinamine

Synonyms—Allylthiocarbamide; Allylthiourea.

Thiosinamine, $CS(NH_2)NHC_3H_5$, may be prepared by mixing 2 parts of volatile oil of mustard with 1 part of dehydrated alcohol, adding 7 parts or excess of solution of ammonia, and heating the mixture at 40° for several hours. The odours of the oil and ammonia disappear and on evaporating the solution the thiosinamine crystallises. It may be decolourised with charcoal. It occurs in the form of white, glistening, prismatic crystals, sometimes odourless, but usually having a faint, garlic-like odour and a bitter taste. When heated, it evolves white alkaline vapours and leaves a carbonaceous residue. The aqueous solution forms a white precipitate with mercuric salts, a grey precipitate with mercurous salts, and a white precipitate with silver nitrate.

Soluble in water (1 in 17), alcohol (1 in 2) and ether.

Standard.—Thiosinamine melts between 72° and 74° . Ash, not more than 0.05 per cent.

Action and Uses.—Thiosinamine has been used as an injection for the removal of scar-tissue, exudates, lymphatic swellings, etc. It has been recommended for Dupuytren's contraction, the scars of burns, cirrhosis of the liver, fibrous ankylosis of joints and stenosis of the alimentary canal. The hypothesis that it causes absorption of fibrous tissue still requires proof. It has been employed in 10 per cent. solution in dilute glycerin, or as *Injectio Thiosinaminæ et Sodii Salicylatis*, to remove fibrous tissue in lupus scars, uterine indurations, urethral strictures, keloid, etc., the dose being 1 millilitre (15 minims). It should be injected in the neighbourhood of the tissue to be absorbed and the injections must be continued for several months. In the form of soap and plaster it has been used in hypertrophic conditions of the skin; it is also used in the form of dusting powder. Internally it has been given in capsules

containing 0.03 to 0.1 gramme ($\frac{1}{2}$ to $1\frac{1}{2}$ grains), with doubtful success, in rheumatic enlargements of the joints; it may also be administered, with caution, in alcoholic solution. Its value is probably negligible and though it is usually well borne, toxic effects sometimes occur; these are nausea, vomiting, headache and fever. Solutions of thiosinamine for **injection**, prepared with the addition of sodium salicylate or phenazone, may be sterilised by tyndallisation or by filtration.

Dose.—0.03 to 0.1 gramme ($\frac{1}{2}$ to $1\frac{1}{2}$ grains).

THIOSINAMINÆ ET ÆTHYLIS IODIDUM.—Thiosinamine ethyl iodide is prepared by combining molecular proportions of thiosinamine and ethyl iodide with the aid of gentle heat. The liquid solidifies on cooling into a crystalline mass. Thiosinamine ethyl iodide is a white, crystalline powder, with a faint odour of mustard oil. It is readily soluble in water (1 in 10), and melts at about 70°. As a fibrolytic agent, thiosinamine ethyl iodide, on account of its iodine content, probably possesses advantages over thiosinamine. It is used in the treatment of difficult and intractable cases of rheumatoid arthritis and allied conditions, and is said to be well tolerated and less depressing than potassium iodide. It may be administered either hypodermically or orally; for the latter purpose it should be given in gelatin capsules. Rapid and complete success is reported from its use hypodermically in the treatment of actinomycosis. An ointment or paint containing 15 per cent. of thiosinamine ethyl iodide may be employed as a local application or for gentle massage. Skin eruptions may occur during the administration of the drug, when it is advisable to discontinue the treatment for a time. A saline draught should be given each morning during the administration of thiosinamine ethyl iodide, and dietetic measures such as the avoidance of wines, beer, stout and red meat should be adopted, and a copious intake of water encouraged. **Dose.**—0.06 to 0.25 gramme (1 to 4 grains) daily, by the mouth; 0.2 to 0.4 gramme (3 to 6 grains) three times weekly, by injection.

Preparation

Injectio Thiosinaminæ et Sodii Salicylatis, B.P.C.—(Inj. Thiosinam. et Sod. Salicyl.)—Injection of Thiosinamine and Sodium Salicylate. Thiosinamine, 10 per cent. w/v, dissolved in an aqueous solution of sodium salicylate with 5 per cent. v/v of glycerin. **Dose.**—0.5 to 1 millilitre (8 to 15 minims), by intramuscular or subcutaneous injection.

THYMI HERBA

(Thym. Herb.)

Thyme

Thyme consists of the dried flowering tops of *Thymus vulgaris* Linn. (Fam. Labiata), a small aromatic shrub indigenous to Southern-Central Europe and widely cultivated in England, France, Germany, Spain and the United States of America.

The slender, ascending, quadrangular branches are from 10 to 20 centimetres long, greyish-brown or purplish in colour, with sessile or shortly stalked, opposite, linear-lanceolate or ovate-oblong leaves up to 9 millimetres long and 2 millimetres wide, with revolute margins and hairy on both surfaces. The shortly-stalked flowers are arranged in axillary and terminal verticillasters. The calyx is 5-toothed and 2-lipped, with a ring of stiff hairs in the throat; the corolla is bilabiate with a 3-lobed underlip and an erect, emarginate upper lip; it is pale rose or white in colour. The odour and taste are agreeable and aromatic.

The diagnostic **microscopical** characters are the epidermis of the leaves, the majority of the cells of which are prolonged with conical trichomes, those on the upper surface being mostly unicellular and up to 60 microns long, and those on the lower surface usually 2 to 3 celled and often knee-shaped, and up to 300 microns long; the presence of labiate stomata and glands, the 6- to 8-celled, uniseriate trichomes from the throat of the calyx, up to 400 microns long; the spherical pollen grains, about 40 microns in diameter.

Thyme **contains** from about 0.4 to 1.5 per cent. of volatile oil.

Standard.—Thyme contains not more than 3 per cent. of foreign organic matter and stems over 1 millimetre in diameter. Acid-insoluble ash, not more than 4 per cent.

Thyme, in powder (Pulvis Thymi Herbæ : Pulv. Thym. Herb.), contains the constituents and possesses the diagnostic microscopical characters of Thymi Herba, and complies with the limit for acid-insoluble ash of the unground drug.

Action and Uses.—Thyme has stimulating and carminative properties. The liquid extract is used in the preparation of cough linctuses.

Preparations

Elixir Thymi, B.P.C.—(Elix. Thym.)—Elixir of Thyme. Each fluid drachm contains $7\frac{1}{2}$ minims of liquid extract of thyme and 2 grains of ammonium bromide, with spirit of chloroform, glycerin, treacle and syrup. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Extractum Thymi Liquidum, B.P.C.—(Ext. Thym. Liq.)—Liquid Extract of Thyme. *Sym.*—Extractum Thymi Vulgaris Liquidum. 1 in 1. Dose.—0.6 to 4 millilitres (10 to 60 minims).

Linctus Diamorphinæ et Thymi, B.P.C.—(Linct. Diamorph. et Thym.)—Linctus of Diamorphine and Thyme. Each fluid drachm contains $\frac{1}{4}$ grain of diamorphine hydrochloride and $\frac{1}{8}$ grain of apomorphine hydrochloride, with liquid extract of thyme, solution of tolu and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

THYMOL

(Thymol)

Thymol

Thymol is 3-methyl-6-isopropylphenol, $\text{CH}_3 \cdot \text{C}_6\text{H}_3(\text{OH}) \cdot \text{C}_3\text{H}_7$, and may be obtained synthetically, or extracted from oil of thyme or from the oils of *Monarda punctata* Linn. (Fam. Labiatae) or *Trachyspermum Ammi* (Linn.) Sprague (Fam. Umbelliferae). Oil of thyme yields about 20 to 30 per cent. of thymol; the other two oils yield respectively about 60 per cent. and about 45 to 55 per cent. It is extracted by distilling off the hydrocarbons and extracting the residue with sodium hydroxide which forms with thymol a soluble sodium derivative. The solution obtained is acidified and the thymol thus liberated is recrystallised from alcohol or light petroleum. Synthetic thymol may be produced from piperitone, menthone, or *p*-cymene.

Thymol occurs in large, colourless, transparent crystals, having a pungent, aromatic, thyme-like odour and a pungent, aromatic taste. It sinks in cold water, but on heating to about 45° it rises to the surface and melts. An alcoholic solution shows no colouration on the addition of ferric chloride solution. The aqueous solution becomes turbid on the addition of bromine water, but no precipitate is produced. When triturated with an equal weight of menthol, phenol, or camphor, liquefaction takes place. If a small crystal is dissolved in 1 millilitre of glacial acetic acid, and 0.3 millilitre of sulphuric acid and 1 drop of nitric acid added, a bluish-green colouration is produced. When 1 gramme is heated on a water-bath with 2.5 millilitres of sodium hydroxide solution diluted with an equal volume of water, a solution is formed which becomes darker on standing, and on adding a few drops of chloroform and shaking, a violet colouration is produced. A purple-red colour is produced when a trace of thymol is heated with chloroform and a trace of potassium hydroxide; this reaction is also given by carvacrol. Thymol in alkaline solution forms a red, insoluble tetraiodo-derivative on adding a solution of iodine.

Soluble in water (about 1 in 1000), alcohol (90 per cent.) (1 in 1), ether (1 in 1.5) and chloroform (1 in 0.6).

Standard, B.P.—Thymol has a melting-point of 48° to 51°. Residue when heated in an open dish on a water-bath, not more than 0.05 per cent. The alcoholic solution is optically inactive and neutral to litmus. The 20 per cent. w/v solution in 10 per cent. w/v sodium hydroxide solution is clear and colourless or pale red; on standing, oily drops do not separate.

Action and Uses.—Thymol resembles phenol in its action, but owing to its insolubility in the fluids of the body it is absorbed much more slowly; it is also less irritant to wounds. Its germicidal action is greater than that of phenol, but less than that of betanaphthol. Its toxicity is about one-fourth that of phenol even after absorption. Thymol is sometimes used as an intestinal antiseptic in doses of 0.12 gramme (2 grains). It may colour the urine green. In oily solution (1 or 2 per cent.) it is applied to the respiratory passages by means of a spray in the treatment of nasal catarrh. The vapour from an alcoholic solution may be inhaled from hot water or from a dry inhaler, in laryngitis and bronchial affections.

Thymol is given internally in large doses, 2 grammes (30 grains) or more, repeated after two hours, to strong, healthy adults to expel intestinal parasites, especially *Ankylostomum duodenale*. It is taken fasting and followed after two hours by a saline purge, and the treatment is continued at weekly intervals until successful. As with other anthelmintics, liberal doses of sodium bicarbonate should be given for three days before the thymol. Between the times of taking the drug and the purge no alcohol or food should be taken, otherwise absorption may take place with production of toxic symptoms. To children and delicate persons not more than 0.6 gramme (10 grains) of thymol should be given. Frequently patients suffer from disagreeable after-effects,

characterised by nausea, vomiting and renal irritation, and carbon tetrachloride or oil of chenopodium is usually more satisfactory. In alcoholic solution, thymol penetrates the skin and produces local anaesthesia.

It is used as an antiseptic lotion and mouth-wash (1 in 2000, or as *Liquor Thymolis Compositus* or *Glycerinum Thymolis Compositum*), as a paint in ringworm (1 in 10 of alcohol, or alcohol and ether), and as an ointment (1 in 24 of soft paraffin, the thymol being dissolved with the aid of heat) for eczema, psoriasis, broken chilblains and parasitic skin affections. An ointment (1 in 12), perfumed with oil of lavender, is used to repel gnats and mosquitoes. For its action as a vermifuge it should be **administered** in a cachet or capsule, alcohol or other solvent being avoided. It is also used as an anthelmintic in veterinary practice.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains); as an anthelmintic, 1 to 2 grammes (15 to 30 grains).

Preparations

Glycerinum Thymolis Compositum, B.P.C.—(*Glycer. Thymol. Co.*)—Compound Glycerin of Thymol. *Syn.*—*Glycerinum Thymol Alkalinum*. An alkaline solution of thymol with other aromatic antiseptics.

Liquor Thymolis Compositus, B.P.C.—(*Liq. Thymol. Co.*)—Compound Solution of Thymol. *Syn.*—*Liquor Antisepticus*; *Antiseptic Solution*. It contains boric and benzoic acids, thymol, eucalyptol, oils of peppermint, sweet birch and thyme, with tincture of baptisia, alcohol (90 per cent.) and distilled water. *Dose.*—0.3 to 2 millilitres (5 to 30 minims).

Nebula Cocainæ Composita, B.P.C.—(*Neb. Cocain. Co.*)—Compound Cocaine Spray. Cocaine, 0.5 per cent. w/v, in compound menthol and thymol spray.

Nebula Mentholis et Thymolis Composita, B.P.C.—(*Neb. Menthol. et Thymol. Co.*)—Compound Menthol and Thymol Spray. Menthol, camphor and phenol, of each 2 per cent. w/v, and thymol, 0.2 per cent. w/v, in light liquid paraffin.

THYMOLIS IODIDUM

(Thymol. Iod.)

Thymol Iodide

Synonym—Dithymol-diiodide.

Thymol iodide, $[\text{C}_6\text{H}_2(\text{CH}_3)(\text{C}_3\text{H}_7)\text{OI}]_2$, may be prepared by the interaction of thymol and iodine. It occurs as a reddish-brown or brick-red, bulky, amorphous powder, having a very slight, aromatic odour; it is almost tasteless. Solutions should be made without the aid of heat and kept in amber-coloured glass bottles, protected from the action of light. On heating, it is decomposed with evolution of iodine vapours. Heated with concentrated sulphuric acid, it is decomposed with separation of iodine. Commercial samples of thymol iodide vary in composition, owing to differences in methods of preparation.

Insoluble in water, alcohol, glycerin, solution of sodium hydroxide,

hot or cold; soluble in ether (1 in 10) leaving a slight residue, chloroform (1 in 50), carbon disulphide, collodion, soft paraffin and fixed and volatile oils.

Standard.—Thymol iodide, determined by the method of the British Pharmacopœia for Iodophthaleinum, contains not less than 40 per cent. of I, calculated on the substance dried over sulphuric acid. Loss on drying over sulphuric acid, not more than 5 per cent. Sulphated ash, not more than 3.0 per cent. Digest 0.1 gramme with 50 millilitres of warm water for ten minutes, filter and cool; the solution complies with the limit test for chlorides (limit of soluble halides). 10 millilitres of water shaken with 0.5 gramme and filtered, forms a solution which is not alkaline to litmus and is not affected by starch mucilage (limit of free iodine).

Action and Uses.—Thymol iodide possesses weak local antiseptic properties and is used as an iodoform substitute. It has the advantage of being practically odourless, but it does not liberate iodine in the tissues and cannot, therefore, replace iodoform in surgery; moreover, on account of its extreme insolubility, even in the alkaline fluids of the body, the thymol is less active in this combination than in the free state. It passes through the body unchanged and unabsorbed. It is used as a dusting powder for burns and wounds, either in the pure state or mixed with 1 to 3 parts of purified talc. It is also used as an insufflation. As an ointment (2 to 10 per cent.), prepared with soft paraffin or hydrous wool fat, it is applied to the skin in eczema, psoriasis, etc.; a 3 per cent. ointment, made with soft paraffin, is applied to the nasal mucous membrane in ozæna.

THYMUS

(Thym.)

Thymus

Synonym—Thymus Siccus.

Thymus consists of the thymus glands of the healthy calf, freed from fat, dried and powdered. It occurs as a yellowish, amorphous powder, with a slight meat-like odour. The powder represents approximately five times its weight of fresh thymus. It is partly soluble in water. The thymus gland occurs as a long, narrow, reddish or greyish lobulated body, situated in front of the chest behind the sternum and partly in the lower portion of the neck, surrounded by a fibrous capsule in which the processes divide the glands into lobes and lobules, the latter being further sub-divided into follicles by fine connective tissues. The thymus is composed of lymphoid tissue. No active principle has been isolated from the thymus gland, and no evidence of the existence of such a principle has yet been adduced.

Action and Uses.—The thymus gland in man reaches its maximum size during the first two or three years of life and then becomes smaller,

usually disappearing with the onset of puberty. The thymus appears to promote growth, to favour calcium retention and to exercise a restraining influence on the reproductive organs. It undergoes atrophy when its function has been accomplished. The gland persists in the condition known as status-thymico-lymphaticus. "Rejuvenation" of the thymus is seen in exophthalmic goitre, acromegaly, Addison's disease and some other endocrine disorders. These cases of general endocrine hypoplasia are chiefly seen in adult life, the females being infantile and the males devoid of secondary sex characteristics. So far as is known there are no clinical indications for the administration of the gland, but it has been recommended in disorders of nutrition in children. It is **administered** in tablets.

Dose.- 0.12 to 0.25 gramme (2 to 4 grains).

THYROIDEUM

(Thyroid.)

Thyroid

Synonyms—Thyroideum Siccum; Dry Thyroid; Thyroid Extract; Thyroid Gland.

Thyroid is obtained from the thyroid gland of the ox, sheep, or pig. The connective tissue and external fat are removed from the glands which are then dried at a temperature not exceeding 60°, powdered, and defatted by extraction with light petroleum. The residue is dried, assayed, and diluted to the required strength with lactose. The organic iodine compounds present in thyroid occur in protein combination as thyroglobulins which are soluble in water. On desiccation of the thyroid gland at a temperature of 40° or below, as much as 70 per cent. of the thyroglobulins remains unaltered and is, therefore, extractable by water. If the desiccation has been done at 100° or by treatment with alcohol, followed by drying at 60°, the thyroglobulins are almost completely denatured and rendered insoluble. These facts have an important bearing on the assay of the official substance.

Thyroid occurs as a cream-coloured, amorphous powder, having a faint, meat-like odour and taste. When a small quantity is boiled for four hours with N/1 sodium hydroxide and the product adjusted to pH 5 by the addition of a 50 per cent. v/v solution of sulphuric acid, a precipitate forms which responds to the test with hydrochloric acid, sodium nitrite and ammonia described under Thyroxinsodium. It should be **stored** in well-closed containers in a cool place.

Partly **soluble** in water, the solution containing the inorganic iodine and the thyroglobulins not denatured during the desiccation of the glands.

Standard, B.P.—Thyroid contains not less than 0.09 per cent. and not more than 0.11 per cent. of iodine in combination as thyroxine, and not more inorganic iodine than 10 per cent. of the content of total iodine.

Action and Uses.—Thyroid exerts a powerful effect on metabolism; following its administration by mouth, the metabolic processes proceed more rapidly and a reduction in body weight occurs. There is an increase in the consumption of oxygen and increased destruction of fats and protein. The administration of thyroid thus increases the available energy, increases the appetite and brightens the mental outlook. Following large doses there is also an increased excretion of water by the kidneys. The chief use of thyroid is in the treatment of cretinism and myxœdema and the dose for the latter purpose should usually not exceed 0.12 gramme (2 grains). Children who are cretins owe their lack of mental and physical development to the non-functioning of the thyroid gland; myxœdematous patients similarly owe their dull mentality and their thickened subcutaneous tissues to a failure of the thyroid to maintain its normal function. Thyroid is also often beneficial in young children who are making little physical and mental progress and in women up to the age of twenty-five. It is also used to relieve œdema, but not œdema due to heart failure.

Thyroid and preparations containing it have been used for the treatment of obesity, but its use for this purpose requires care since a rapid loss of fat from the heart walls is dangerous; in some cases, notably those which show a resemblance to myxœdema, and in obesity developing at the menopause, it is apparently satisfactory. Excessive doses of thyroid may increase the pulse rate, lower arterial pressure and give rise to restlessness, insomnia and palpitation of the heart. As the aim of thyroid administration is to bring the rate of metabolism up to normal, the dose and frequency of administration can best be suited to individual needs by determination of the basal metabolic rate.

Some difficulty has arisen in the past over the interpretation of doses of thyroid, owing to uncertainty whether the prescriber intended grains of fresh gland or grains of desiccated gland. Doses of the British Pharmacopœia refer to the desiccated and standardised powder. The unstandardised gland, whether fresh or dry, may vary more than sixfold in its content of active material.

Dose.—0.03 to 0.3 gramme ($\frac{1}{2}$ to 5 grains).

Preparation

Extractum Thyroidei Liquidum, B.P.C.—(Ext. Thyroid. Liq.)—Liquid Extract of Thyroid. 1 in 4 $\frac{1}{2}$. Dose.—0.06 to 1.2 millilitres (1 to 20 minims).

THYROXINSODIUM

(Thyroxinsod.)

Thyroxine-sodium

Thyroxine-sodium is the monosodium salt of *dl*- β -[3:5-diiodo-4-(3':5'-diiodo-4'-hydroxyphenoxy) phenyl]- α -aminopropionic acid. It

may be obtained by the action of sodium carbonate on thyroxine which is obtained by the controlled hydrolysis of thyroid gland with barium hydroxide, and subsequent purification. Thyroxine can also be prepared synthetically. Thyroxine-sodium occurs as a white, crystalline powder. It is unstable in alkaline solutions. When a trace is dissolved in alcohol (50 per cent.) with the aid of one drop of hydrochloric acid, and one drop of a 20 per cent. w/v aqueous sodium nitrite solution is added, a yellow colour is produced which deepens on boiling; on cooling and adding excess of strong solution of ammonia, the colour changes to red. It should be **stored** in well-closed containers.

Slightly **soluble** in water; more soluble in solutions of sodium carbonate or sodium hydroxide.

Standard, B.P.—Thyroxine-sodium contains not less than 61 per cent. and not more than 65 per cent. of I.

Action and Uses.—Thyroxine-sodium is used for the same purposes as thyroid; it is the usual form for the administration of thyroxine, and when thyroxine is ordered, thyroxine-sodium may be dispensed. The action of thyroxine-sodium is qualitatively similar to that of thyroid, but the activity of the latter is quantitatively greater than that of the thyroxine-sodium equivalent to its thyroxine content. When given by mouth or by intravenous injection it does not usually cause an immediate effect, but in from twenty-four to thirty-six hours there is an increase in pulse rate. It is said that the maximum effect from a single injection is not reached until the tenth day and that the duration of the effect of a single administration of thyroxine-sodium is about three weeks. Repeated administration of small doses produces a greater effect than a single large dose. Thyroxine-sodium is indicated in cases of deficient or absent thyroid functioning, such as simple goitre, cretinism and myxœdema. Its use is contra-indicated in cases of exophthalmic goitre.

It is usually **administered** by intravenous injection, but may be given by mouth, although its absorption from the gastro-intestinal tract is uncertain. It is desirable that the optimum dose should be ascertained by trial for each case. The exact determination of the dose may be made by determining the basal metabolic rate. One milligram of thyroxine-sodium increases the basal metabolic rate in normal adults by approximately 2.5 per cent. In a normal adult, 0.002 gramme ($\frac{1}{50}$ grain) per day will produce evidence of hyperthyroidism, that is, loss of weight, increased pulse rate, nervous manifestations and a sense of fatigue. Cases of myxœdema require from 0.0015 to 0.002 gramme ($\frac{1}{40}$ to $\frac{1}{50}$ grain) of thyroxine-sodium per day. A cretin usually requires from 0.0002 to 0.0004 gramme ($\frac{1}{2500}$ to $\frac{1}{1250}$ grain) daily or on alternate days. Thyroxine-sodium in doses of 0.002 gramme ($\frac{1}{50}$ grain) is used in the treatment of pre-eclamptic toxæmia when retention of fluid is the main symptom. It has also been reported successful in the treatment of acute mercurial poisoning in doses of 0.0015 gramme ($\frac{1}{40}$ grain) daily for three days. Solutions of thyroxine-sodium for **injection** may be prepared

by aseptic methods and should be used within twenty-four hours of their preparation.

Dose.—0.0001 to 0.001 gramme ($\frac{1}{8000}$ to $\frac{1}{800}$ grain).

TILIA

(Tilia)

Tilia

Synonyms—Tilleul; Lime Flowers; Linden Flowers; Lime Tree Flowers.

Tilia consists of the dried inflorescences, with their attached bracts, of *Tilia europæa* Linn., *T. cordata* Mill. and *T. platyphyllos* Scop. (Fam. Tiliaceæ), collected when the flowers are fully expanded. It should be **stored** in well-closed containers and protected from the light and should not be used after being stored for more than 12 months from the date of collection.

The inflorescence is a dichasial cyme of from 1 to 15, usually 3 to 7, flowers which are brownish in colour and are borne upon a peduncle 6 to 9 centimetres long which is adnate to the bract for about one-third of its length from the base. The pedicels are up to about 2 centimetres long and the flowers are about 5 to 10 millimetres broad. Each flower has 5 hairy sepals, 5 petals, numerous stamens, often united in 5 groups, and 5 carpels united to form a superior ovary with 5 loculi each containing 2 ovules. The pale yellowish-green bract is linear-lanceolate, up to about 10 centimetres long and 2 centimetres wide, with an entire margin, a conspicuous pinnate venation and an obtuse apex. The odour is faintly aromatic and the taste mucilaginous. Tilia **contains** volatile oil, mucilage, sugar and tannin.

Action and Uses.—Tilia is rarely used in medicine. It is reputed to have antispasmodic and diaphoretic properties and, as a domestic remedy, is **administered** in the form of fresh infusion.

TOLUENUM

(Toluen.)

Toluene

$C_7H_8 = 92.06$

Synonyms—Toluol; Methylbenzene.

Toluene, $C_6H_5 \cdot CH_3$, is obtained by fractionation of the refined light oil of coal tar. It was originally obtained by the dry distillation of balsam of tolu, hence its name. It occurs as a colourless, light, mobile, highly

refractive liquid with a characteristic odour, and burns with a luminous and very sooty flame. Specific gravity, about 0.87. Boiling-point, about 111°. Flash-point, about 7°. It is oxidised by heating with chromic acid, dilute nitric acid, or alkaline potassium permanganate solution with the formation of benzoic acid. Substitution is mainly directed into the *o*- and *p*- positions. The *o*- and *p*-sulphonic acids of toluene are intermediate products in the manufacture of saccharin and chloramine, whilst 2 : 4 : 6-trinitrotoluene is an important explosive. Toluene is also the starting point in the synthesis of many other compounds, such as benzaldehyde, benzoic acid, etc. It is readily distinguished from benzene by remaining liquid at -20°. Toluene dissolves sulphur, phosphorus, iodine, etc. When used for the sterilisation of catgut it should be free from thiophene.

Soluble in alcohol, ether, chloroform, carbon disulphide, acetone and glacial acetic acid; insoluble in water.

Uses.—Toluene is used as a preservative of urine before chemical examination and for the sterilisation of catgut.

SOLVENT-NAPHTHA, consisting principally of xylenes and trimethylbenzenes, and boiling between 140° and 180°, is used for chemical washing, extraction of perfumes and in the linoleum, rubber and varnish industries. It should be distinguished from solvent mineral naphtha, which is a petroleum product

XYLENUM.—Xylene, or xylol, is dimethylbenzene, $C_6H_4(CH_3)_2$. It occurs naturally in some petroleum oils, and is obtained by the fractionation of the refined light oil of coal tar. It is a mixture of *o*-, *m*-, and *p*-xylenes, and occurs as a thin, white, mobile liquid resembling benzene and toluene and having a peculiar odour. It solidifies at about -28° and boils at about 140°. The specific gravity is about 0.865. It is insoluble in water; soluble in alcohol, ether, chloroform, etc. Xylene is used to sterilise catgut ligatures and as a clearing agent in microscopy.

Preparation

Pigmentum Mentholis et Tolueni, B.P.C.—(Pig. Menthol. et Toluen.)—Menthol and Toluene Paint. *Syn.*—Löffler's Paint. Menthol, 10 per cent. w/v, with dehydrated alcohol, strong solution of ferric chloride and toluene.

TONCO SEMEN

(Tonco Sem.)

Tonka Seed

Synonyms—Tonka Beans; Tonquin Beans.

Tonka seed is derived from the seeds of two species of *Dipteryx* (Fam. Leguminosæ), namely *D. odorata* Willd., a native of Guiana, and *D. oppositifolia* Willd., a large tree indigenous to Brazil. The seeds are dried in the sun or exported to Trinidad and there "cured" or "frosted" by steeping in rum for a few days and spreading them out to dry.

The seeds are exalbuminous and are usually 3 to 4 centimetres long, 10 millimetres wide and 8 millimetres thick, flattened, ovoid, rounded at one extremity and somewhat pointed at the other. The brittle testa is coarsely wrinkled internally and is nearly black in colour and, in the case of frosted seeds, covered with minute crystals of coumarin; one edge of the seed is acute and the other rounded. The embryo consists of two large, brown cotyledons enclosing a plumule and a short, thick radicle. The seeds have a marked fragrant odour and a somewhat bitter taste. Tonka seed **contains** coumarin, which may be present to the extent of about 3 per cent. Fixed oil, about 45 per cent., and proteins are also present.

Action and Uses.—Tonka seed was formerly used as the source of coumarin, but the greater part of this substance employed is now produced synthetically. It is used in perfumery.

TOTAQUINA

(Totaquin.)

Totaquine

Totaquine is a mixture of alkaloids obtained from the bark of various species of *Cinchona* such as *C. succirubra* Pavon and *C. robusta* Howard. Its introduction was suggested by the Malaria Commission of the League of Nations in 1931 as a substitute for quinine. It occurs as a nearly colourless or pale yellowish-grey or brown powder, without odour but having a bitter taste. The alcoholic solution is alkaline to litmus. When heated in a dry tube it chars and evolves an alkaline vapour. A dilute aqueous solution, prepared with the aid of a small quantity of dilute sulphuric acid, shows a blue fluorescence. It responds to the test with bromine water and dilute solution of ammonia described under Quinine.

Almost **insoluble** in water; almost completely soluble in warm alcohol (95 per cent.) and chloroform; partly soluble in ether, benzene and light petroleum.

Standard, B.P.—Totaquine contains not less than 70 per cent. of crystallisable cinchona alkaloids, of which not less than one-fifth is quinine. Loss on drying for one hour at 70° and finally at 100°, not more than 5 per cent. Ash, not more than 5 per cent.

Action and Uses.—Totaquine is administered by the mouth in benign and malignant tertian malaria, but it possesses no advantages over quinine except that of cheapness. It was introduced with the intention of providing a cheap substitute for quinine for use in India, etc.

Dose.—0.06 to 0.6 gramme (1 to 10 grains).

TOXINUM DIPHThERICUM CALEFACTUM

(Toxin. Diphtheric. Calefact.)

Schick Control

Synonyms—Diphtheria Toxin (Heated) for Schick Test Control; Schick Test Control.

Schick control consists of Schick test toxin subjected to a temperature of not less than 70° for not less than five minutes, which is sufficient to destroy the specific toxin without destroying the non-specific reactive principles. It is prepared from the same batch of toxin as that with which it is issued for use.

Standard, B.P.—Schick Control complies with the tests for sterility described in regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—The Schick control is used to distinguish between the true Schick reaction due to the absence of antitoxin and the *pseudo* reaction due to the susceptibility to the bacterial proteins.

Dose.—0·2 millilitre (3 minims), by intradermal injection.

TOXINUM DIPHThERICUM DETOXICATUM

(Toxin. Diphtheric. Detoxicat.)

Diphtheria Prophylactic

Diphtheria prophylactic consists of the sterile filtrate or a preparation of the filtrate from a broth culture of *Corynebacterium diphtheriae*, so modified by physical or chemical means or by the addition of antitoxin that it is non-toxic but antigenic, that is, no symptoms follow injection but immunity results. The following are the chief types of diphtheria prophylactic:—

(a) Diphtheria toxin-antitoxin mixture is prepared by adding diphtheria antitoxin to the filtrate from a culture of *C. diphtheriae*. This form of diphtheria prophylactic is not much used in Great Britain although it has been very widely used in America. Its great disadvantage is that when stored below 0° it may become dangerously toxic owing to destruction of the antitoxin; other forms of diphtheria prophylactic are stable at this temperature.

(b) Diphtheria toxoid, or anatoxin, is a harmless modification of diphtheria toxin present to a varying degree in all filtrates from cultures of *C. diphtheriae*, and as filtrates "age" more toxin changes into toxoid. The usual method of producing this change completely is by the action of 0·2 per cent. formaldehyde solution upon the toxin (without other preservative) for a period of three to four weeks at a temperature of 27°. The optimum quantity of formaldehyde and the time required to change all the toxin into toxoid varies slightly according

to the type of nutrient broth used in the preparation of the toxin (broth prepared from horse flesh is not used because of the possibility of sensitising individuals to subsequent injections of horse serum). The action of formaldehyde is considered complete and the filtrate contains only toxoid and toxin when no symptoms follow the injection into guinea-pigs of 5 millilitres subcutaneously and 0.2 millilitre intradermally. When this stage is reached, the product is filtered through porcelain candles and tested for non-toxicity, sterility and immunising value. The toxoid thus prepared by the action of formaldehyde is referred to as formol-toxoid; in France, the same material is termed "anatoxine." Diphtheria toxoid is a clear liquid of a colour slightly darker than that of the broth from which it is prepared.

(c) Diphtheria toxoid-antitoxin mixture consists of toxoid sufficiently neutralised by antitoxin and suitably diluted in physiological solution of sodium chloride. The antitoxin may be derived from the serum of immunised horses or other animals. Diphtheria toxoid-antitoxin mixture is a clear and almost colourless liquid.

(d) Diphtheria toxin-antitoxin floccules are prepared by mixing diphtheria antitoxin and the filtrate from a broth culture of *C. diphtheriae* in the proportion necessary to produce flocculation, separating the floccules, washing and suspending them in physiological solution of sodium chloride.

(e) Diphtheria toxoid-antitoxin floccules consist of a suspension in physiological solution of sodium chloride of the precipitate formed when toxoid is mixed with antitoxin in suitable proportions. Toxoid-antitoxin floccules are a fine suspension of white particles in a colourless liquid.

Diphtheria prophylactic is **stored** in glass containers sealed so as to exclude bacteria. If the container includes more than one dose and allows successive doses to be withdrawn, an antiseptic is added which is at least as effective as 0.5 per cent. w/v of phenol. In the form of toxin-antitoxin mixture, diphtheria prophylactic retains its potency for not less than eighteen months when stored between 0° and 10°; when stored below 0°, it may become dangerously toxic. The undiluted toxoid, stored at room temperature, retains its potency for not less than two years.

Standard, B.P.—All forms of diphtheria prophylactic comply with tests to ensure that the toxicity has been sufficiently reduced and that the potency as an immunising antigen has been preserved, as described in regulations made under the Therapeutic Substances Act, 1925. The toxicity is determined by injection into guinea-pigs. Five times the adult dose, injected subcutaneously into each of five guinea-pigs weighing 250 to 350 grammes, should not cause the death of any within six days. If any die from the specific toxæmia within thirty days following the injection, the test is repeated, giving one adult dose to each of five guinea-pigs. It should not cause any death within thirty days. An injection into each of ten guinea-pigs of five times the adult dose, or of one-tenth the adult dose repeated after an interval of not more than four weeks, confers an immunity which is indicated by the production of a

Schick-positive reaction in not more than two of the animals after the injection of one test dose of Schick test toxin, or by the death of not more than two of the animals after the injection of five lethal doses of diphtheria toxin. The immunity tests are made at about the sixth week after the single injection, or at about the third week after the second of the two injections. Diphtheria toxoid is a more potent antigen than most of the other types of prophylactic, but there is not yet any standard method of testing. The combining power with antitoxin measured by the flocculation reaction forms an indication of antigenic value. The immunising value of different batches of toxoid can be compared by testing the amount of antitoxin produced in guinea-pigs at a definite interval after subcutaneous injection. Toxoid-antitoxin mixture and toxoid-antitoxin floccules can be compared by testing the rapidity with which guinea-pigs become Schick-negative after subcutaneous injection (immunity index method).

Action and Uses.—Diphtheria prophylactic is used for active immunisation against diphtheria. For this purpose, it is necessary to present diphtheria toxin in a harmless form, either in combination with antitoxin or modified to toxoid. A person who gives a negative reaction to the Schick test is considered to be immune to diphtheria. In a person not immune a single injection of diphtheria prophylactic produces this degree of immunity only if the individual is already partly immune through natural causes. The injection of diphtheria prophylactic into a non-immune person is followed some weeks later by an increased power to respond to subsequent injections. No antitoxin may be produced as a result of the first injection, but a second or third injection given three or four weeks later results in antitoxin production. Except in the case of young children, it is usual to conduct a Schick test before employing diphtheria prophylactic. Persons who give a positive reaction to this test receive two or more doses of diphtheria prophylactic and are again Schick-tested after the lapse of some weeks to ascertain if immunity has been established.

Diphtheria toxoid is one of the most widely used forms of diphtheria prophylactic and the usual system of dosage is 1 millilitre (15 minims) subcutaneously, followed three weeks later by a second dose of 1 millilitre, and one to two weeks later by a third dose of 1 millilitre. Immunity is usually established five or six weeks after the third dose. Many adults are susceptible to material in the prophylactic other than specific toxoid, and severe reactions may follow injection of doses of 1 millilitre. It is, therefore, advisable to test the susceptibility of all adolescents by the so-called Moloney test, a preliminary injection of a small quantity (0.1 millilitre or less) of the toxoid diluted with normal saline, and any reaction occurring within 24 to 48 hours must be taken as indicating that toxoid is unsuitable for that individual and toxoid-antitoxin floccules should be used instead. A non-specific reaction occurs least frequently after toxoid-antitoxin floccules, most frequently after toxoid. In the case of diphtheria toxoid-antitoxin mixture, it is usual to give three doses, each of 1 millilitre, with an interval of a week between each

dose. Immunity is established about ten or twelve weeks after the third dose.

Dose.—The volume indicated on the label, on two or three occasions, at intervals of two or four weeks, by subcutaneous injection.

TOXINUM DIPHThERICUM DIAGNOSTICUM

(Toxin. Diphtheric. Diagnost.)

Schick Test Toxin

Schick test toxin is a sterile filtrate from a culture on nutrient broth of *Corynebacterium diphtheriae*, which is diluted before use with an appropriate solution of sodium chloride so that the test dose is contained in 0.2 millilitre (3 minims). The toxin from which the dilution is prepared is allowed to mature for at least a year until it has become relatively stable. Dilutions in physiological saline solution are very unstable. The use of buffer solutions, such as isotonic borax and boric acid solution, greatly increases the stability of toxin dilutions and appropriate dilutions remain stable for several months at room temperature.

Schick test toxin is supplied in both undiluted and diluted forms. In the undiluted form, Schick test toxin occurs as a clear, yellow liquid free from suspended particles. The diluted toxin is a clear, colourless liquid. It should be **stored** in glass containers sealed so as to exclude bacteria. The undiluted form is supplied with an accompanying container of a sterile solution of sodium chloride of the required strength and volume to give, when mixed with the undiluted toxin, a solution isotonic with blood and containing one test dose in 0.2 millilitre (3 minims). This procedure is dangerous because the amount issued approaches the human fatal dose, and it is undesirable because the physician cannot dilute the toxin with any degree of accuracy. The issue of Schick toxin diluted in buffer solutions can replace the issue of toxin to be diluted before use. If undiluted, it retains its potency for six months when stored at a temperature not exceeding 10°. When diluted with sodium chloride solution only, it loses its potency in a few days even in the ice-chest. When diluted with a buffer solution rendered isotonic with blood by the addition of sodium chloride, it retains its potency for at least two months at temperatures not exceeding 25°.

Standard, B.P.—Schick test toxin complies with tests for sterility described in regulations made under the Therapeutic Substances Act, 1925. One test dose, mixed with $\frac{1}{1250}$ unit or less of diphtheria antitoxin and injected into guinea-pigs, gives a positive Schick reaction, but no reaction of any kind when mixed with $\frac{1}{750}$ unit or more of the antitoxin. When injected into guinea-pigs without admixture with antitoxin, a positive Schick reaction is obtained with one twenty-fifth but not with one fiftieth of a test dose.

Action and Uses.—The Schick test is employed for the detection of susceptibility to diphtheria. Very small amounts of diphtheria toxin (from one thousandth to one millionth of a millilitre of a toxin of moderate strength), injected intracutaneously into a non-immune individual, or into a normal guinea-pig or rabbit, will cause a definite reaction—a red flush 10 millimetres or more in diameter. Slightly larger doses cause a larger area of reaction, followed by staining and slight desquamation. A further increase in dose causes necrosis, and a still larger dose may cause death. It is necessary, therefore, to limit the amount of toxin injected in the Schick test. In practice it has been found that no inconvenient reactions are caused in man if one-fiftieth of the Schick dose causes no reaction when injected into the skin of a normal guinea-pig. Further, it has been found that definite reactions, easily read, follow the injection intracutaneously into man of that dose of toxin of which one twenty-fifth causes a definite flush when injected into the skin of a normal guinea-pig. If the blood of an individual contains sufficient antitoxin, the injection of a fixed amount of toxin does not produce a reaction. The injection of a safe dose of toxin can therefore be used as the basis of a test for the presence or absence of a certain amount of antitoxin. The concentration of antitoxin in the blood of an individual, which determines the presence or absence of a reaction, does not depend on the specific toxin content of the material injected. The amount of antitoxin with which any culture filtrate combines, depends on the amount of toxin present together with the toxoid, i.e., that modification of toxin which occurs when a toxin “ages” or is chemically changed and which, although capable of combination with antitoxin, is not poisonous and will not cause death, œdema or skin lesion. The Schick dose must consequently be defined in terms of its combining power with antitoxin. A mixture of one test dose of Schick toxin with $\frac{1}{750}$ unit of antitoxin must cause no reaction, and a similar mixture with $\frac{1}{1250}$ unit of antitoxin must give a definite flush when injected into the skin of normal guinea-pigs.

The Schick test is carried out by the intradermal injection of 0.2 millilitre of Schick test toxin. The antero-internal aspect of the forearm is a convenient site for the injection and the skin should first be cleansed with alcohol or soap and water.

Such an injection causes no reaction in man if the individual is immune to diphtheria. If the individual is not immune, the injection is followed by a red flush, 10 to 20 millimetres in diameter, visible twenty-four to thirty-six hours later. This fades and becomes brown, and desquamation may follow. The test is complicated by the fact that many people, particularly adults, are sensitive to constituents of the test material other than the specific toxin. The diphtheria bacillus, when cultivated on artificial media, produces, in addition to specific toxin and toxoid, bacterial proteins and possibly other metabolic products. These products are more heat-stable than the specific toxin, and a true Schick reaction can be distinguished from a non-specific pseudo-reaction by a comparison between the reactions produced by the Schick test toxin

and the Schick control. The reaction obtained by the injection of Schick test toxin into one forearm is compared with the reaction obtained by the injection of Schick control into the other.

The reaction is interpreted as follows:—

(a) *Negative*, if there is no reaction in both arms.

(b) *Positive*, if there is no reaction on the control arm, but a red flush begins to develop on the test arm after twenty-four to thirty-six hours and reaches its maximum in four days. At this time it is a circumscribed area measuring 10 to 20 millimetres in diameter. During the next seven to ten days it fades slowly, showing superficial scaling and a persistent, brownish pigmentation.

(c) *Pseudo*, or *negative and pseudo*. A red flush develops rapidly in twenty-four hours equally on each arm, but is less circumscribed than the positive reaction. By the fourth day it has practically disappeared, often leaving a reddish or brownish pigmentation.

(d) *Combined*, or *positive and pseudo*. The pseudo effect develops rapidly on both arms, and as this fades the positive reaction develops on the test arm. In this way, the test arm tends to acquire the characters of the true positive, while the control arm is clearing up. If it is possible to take a reading on one occasion only, this should be done not earlier than the fourth day and not later than the seventh. In most cases the pseudo reaction will have subsided by this time.

The conclusions drawn from these results are as follows:—If the result is *negative*, or *negative and pseudo*, the patient is immune; if *positive* or *positive and pseudo*, the patient is susceptible. The Schick test is not considered an essential preliminary to immunisation for children under six months of age, since usually they are naturally immune to diphtheria, or for children between the ages of six months and six years since the majority of children between these ages give a positive Schick reaction. Above six years of age, immunity varies greatly and the test should always be conducted.

Dose.—0·2 millilitre (3 minims), by intradermal injection.

TOXINUM SCARLATINUM

(Toxin. Scarlatin.)

Streptococcus Toxin (Scarlatina)

Synonym—Scarlet Fever Streptococcus Toxin.

Streptococcus toxin (scarlatina) is the diffusible exotoxin obtained from a broth culture of a good toxin-producing strain of *Streptococcus hæmolyticus scarlatinæ*. A potent toxin may be prepared by growing the streptococcus in peptone broth (pH 7·5), with 5 per cent. of sterile, defibrinated rabbit's blood. The culture is centrifuged, the supernatant liquid is filtered through a Berkefeld filter,

and to the filtrate 0.5 per cent. of phenol is added as a preservative. Streptococcus toxin (scarlatina) should be **stored** at as low a temperature as possible. If kept in an ice-chest in the dark it can be regarded as of full potency for two to three months. The toxin should be issued in sterilised glass containers sealed so as to exclude bacteria and marked with a date beyond which the toxin is not intended to be used.

Standard.—Streptococcus toxin (scarlatina) complies with the tests for sterility described in regulations made under the Therapeutic Substances Act, 1925. The potency of the toxin is expressed in terms of skin-test doses (S.T.D.). One skin-test dose is the amount of toxin which, when injected intradermally, will give a zone of erythema, 10 millimetres or more in diameter, in the majority of susceptible persons.

Action and Uses.—Streptococcus toxin (scarlatina) is used in the Dick test for susceptibility to scarlet fever. For this purpose the toxin should be diluted with normal saline solution (approximately 1 in 1000), so that a skin-test dose is contained in 0.1 to 0.2 millilitre ($1\frac{1}{2}$ to 3 minims). The technique of the injections is practically the same as that employed for the Schick test. The skin in front of the forearms is carefully cleansed with ether or alcohol, and 0.2 millilitre (3 minims) of the diluted toxin is injected intradermally into one arm. Sometimes 0.2 millilitre of control fluid, consisting of diluted toxin which has been inactivated by heating to 96° for from two to four hours, is injected into the other arm, but in view of the rarity of pseudo-reactions it is generally agreed that the use of such a control is not necessary. The positive reaction develops in from three to twelve hours as a bright red flush with average dimensions of 20 to 30 millimetres. It has usually reached its maximum in eighteen hours and then rapidly fades.

In the Dick-negative individual there is no significant reaction on either arm. About 20 per cent. of children at the age of two, and 70 to 90 per cent. of adults, are Dick-negative. The Dick test is positive in some 80 per cent. or more of patients suffering from definite scarlet fever during the first two days of the attack, and usually becomes negative at about the sixth to twelfth day. In a few cases it may remain positive for several weeks or even throughout the disease. The change from positive to negative in the course of an illness with rash is, however, diagnostic of scarlet fever. The detection of susceptible contacts and others by means of the Dick test and their passive immunisation by means of streptococcus toxin (scarlatina) are important administrative measures in the control of scarlet fever. In hospitals it is becoming increasingly common to immunise the nursing staff and others liable to be exposed to infection; active immunisation has afforded protection in many institutions and the immunity so acquired has continued for a considerable period. Subjects with a negative reaction, either natural or following immunisation, are almost invariably immune against scarlet fever.

Streptococcus toxin (scarlatina) is also used for active immunisation of persons who react positively to the Dick test. For this purpose the toxin

should be diluted so that the required dose is contained in a volume convenient for injection. From three to five doses of toxin are usually given at weekly intervals, although the interval between the later doses is sometimes lengthened to a fortnight. It is generally agreed that the initial dose should be 500 skin-test doses or, if the patient gives a strongly positive reaction to the Dick test, 250 skin-test doses, injected subcutaneously or, preferably, intramuscularly. Subsequent doses gradually increasing up to 20,000 or even 80,000 skin-test doses should be given to complete the course. If the patient has shown a large positive reaction and the dose is increased too rapidly, he may show the "scarlatinoid syndrome," namely, vomiting, malaise and a scarlatiniform rash which disappears in twenty-four to forty-eight hours. The majority of positive reactors apparently become negative within a few weeks of the last dose and remain so for at least twelve months. It is advisable to Dick test those specially exposed, such as nurses, every year, and if positive, to give a further injection of 20,000 skin-test doses or more. In some cases the injection of immunising doses of the toxin is followed by a reaction; it is said that this can be prevented by injecting 0.2 to 0.3 millilitre (3 to 5 minims) of solution of adrenaline hydrochloride with the toxin.

TRAGACANTHA

(Trag.)

Tragacanth

Synonym—Gum Dragon.

Tragacanth is the dried, gummy exudation obtained by incision from *Astragalus gummifer* Labill. and some other species of *Astragalus* (Fam. Leguminosæ), and is known in commerce as Persian tragacanth. The species of *Astragalus* are shrubs indigenous to Greece, the Turkish Empire and Persia. The cell walls of the pith and medullary ray cells undergo gummosis, when they swell by the absorption of water and exert considerable pressure in the interior of the stem, the gummy substance eventually forcing its way through natural crevices or artificial incisions in the bark. The exudation is collected when dry and graded. That which has been exuded through elongated incisions dries in flakes and is known as "flake" tragacanth, in which form alone it is official.

Tragacanth occurs in thin, flattened, more or less curved, ribbon-like flakes, about 25 millimetres long and 12 millimetres broad. It is white or pale yellowish-white, horny, translucent, marked on the flat sides with concentric ridges, and breaks with a short fracture. It is odourless and tasteless. Tragacanth is only sparingly soluble in water, but swells into a homogeneous, adhesive, gelatinous mass; it usually contains a small amount of starch which stains with N/50 iodine and then appears as minute, scattered, blue specks, the remainder of the tragacanth staining yellow.

The diagnostic **microscopical** characters are the gradual swelling and extension of the angular particles of the powdered drug until their form eventually disappears, when mounted in water; the presence of only a few groups of small, rounded starch grains; the absence of any colouration when mounted in solution of ruthenium red.

The **composition** of tragacanth has not yet been satisfactorily ascertained. The part soluble in water appears to consist chiefly of polyarabinantrigalactangeddic acid and yields on hydrolysis arabinose, galactose and geddic acid. The portion insoluble in water yields, under the influence of baryta water, isomeric α - and β -tragacanthanxylanbassoric acids, which yield on hydrolysis tragacanthose, xylose and bassoric acid. Traces of starch and of altered cellulose are also to be found in the gum.

Substitutes.—"Vermicelli" tragacanth is composed of tears and vermiform pieces which have been formed by exudation through more or less rounded holes. Smyrna tragacanth occurs in flakes, but is more opaque and less ribbon-like than the official drug; it contains appreciable quantities of starch. Hog gum, or Caramania gum, occurs in yellowish or yellowish-brown, opaque tears or vermiform pieces, which are occasionally whitened by dusting them with lead carbonate; it is said to be obtained from a species of *Prunus* (Fam. Rosaceæ). Indian tragacanth (sterculia gum; Karaya gum) is obtained from *Sterculia urens* Roxb. (Fam. Sterculiaceæ). It occurs in irregular, striated, often vermiform, whitish or pinkish-brown pieces, occasionally with fragments of bark attached; it has a distinctly acetous odour. Boiled with solution of potassium hydroxide it assumes at most a slight brownish colour, whereas tragacanth turns canary-yellow; when the powder is mounted in solution of ruthenium red, the particles are stained bright pink. The volatile acidity, after hydrolysis with 5 per cent. phosphoric acid, is about 18 per cent., calculated as acetic acid; tragacanth gives only from 2 to 3 per cent. Indian tragacanth yields from 5 to 6 per cent. of ash.

Standard, B.P.—Tragacanth contains not more than 2 per cent. of foreign organic matter. When powdered, it does not acquire a pink colour in solution of ruthenium red. Ash, not more than 4 per cent.

Tragacanth, in powder (*Pulvis Tragacanthæ* : *Pulv. Trag.*), possesses the microscopical characters of *Tragacantha*, and complies with the limit for ash and the reaction with ruthenium red of the unground drug.

The following test provides a useful means of comparing specimens of tragacanth, but it is necessary that tests should be carried out at the same time and under exactly the same conditions if comparative results are to be obtained:—The tragacanth should be in the form of powder, or, if in flake form, should be reduced to a powder which passes a No. 30 sieve and is retained by a No. 60 sieve. Prepare a mucilage of 1·25 per cent. strength as described in the British Pharmacopœia for *Mucilago Tragacanthæ*; heat for one hour on a boiling water-bath, with occasional stirring, pour it into a 50 millilitre Nessler cylinder and allow it to stand overnight. At the surface of this mucilage release a steel ball, $\frac{1}{8}$ inch in diameter, and take the time of fall from a point 1·5 inches to a point 4 inches below the upper surface; the time required is from 50 to 150 seconds for average specimens of tragacanth when freshly powdered. Occasional specimens give much higher results.

Uses.—Tragacanth is employed in pharmacy as a suspending agent

in mixtures containing resinous tinctures and heavy insoluble powders, or to emulsify volatile oils. Mucilage of tragacanth and compound powder of tragacanth are used for these purposes, the latter combining the suspending powers of tragacanth and acacia, while the starch present tends to prevent agglomeration of the deposit. It is not a suitable emulsifying agent for fixed oils since the resulting emulsions are very coarse, but it is commonly incorporated in emulsions prepared with acacia in order to retard creaming. The mucilage of tragacanth is an efficient suspending agent for the resins of tincture of jalap and tincture of myrrh; it is also employed instead of acacia when substances incompatible with the latter are present. In some cases, mucilage of tragacanth answers better than mucilage of acacia, or a mixture of the two mucilages may give the best results, as with compound tincture of benzoin and tincture of tolu. It is worthy of note that the addition of mucilage of acacia to mucilage of tragacanth produces a thinner mixture than the addition of a similar quantity of water. Mucilage of tragacanth is preferred to mucilage of acacia for use in lotions for external use. With essential oils, tragacanth forms coarse emulsions which separate on standing, but are readily miscible. The following procedure may be followed:—Add the gum to the oil in a dry bottle in the proportion of 1 part of tragacanth to 10 parts of oil, shake, add 72 parts of water and agitate vigorously; then add water in successive portions to produce the required volume.

Tragacanth is largely used as a constituent of glycerin toilet creams and jellies. It is also used to form a drying application to the skin, which may be used as a basis for ichthammol, salicylic acid, resorcinol, sulphur, etc. A typical preparation, known as Bassorin Paste or Lini-mentum Exsiccans, is made by mixing in a wide-mouthed bottle 5 parts of tragacanth, in powder, with 10 parts of alcohol, adding 70 parts of water, shaking vigorously and adding 2 parts of glycerin with sufficient water to make 100 parts. It dries on the skin, forming a transparent film easily removed by washing. A somewhat similar preparation, known as Gelanthum or Unna's Jelly, contains tragacanth, gelatin, glycerin and water, with a little thymol; it is used as a base for skin medication. Tragacanth is used sparingly as an excipient to bind pill masses; glycerin of tragacanth is a useful excipient which should be used in the smallest possible quantity, the mass being well kneaded. Glucanth is a pill excipient prepared by mixing 1 part of tragacanth, in powder, with 1 part of distilled water and 4 parts of syrup of liquid glucose. Tragacanth is also used as the basis of lubricants for catheters and surgical instruments. It is also used for supporting dentures.

Preparations

Glycerinum Tragacanthæ, B.P.C.—(Glycer. Trag.)—Glycerin of Tragacanth. About 1 in 5½.

This glycerin was included in the British Pharmacopœia, 1914.

Lotio Tragacanthæ, B.P.C.—(Lot. Trag.)—Tragacanth Lotion. *Syn.*—Lotio Emolliens. Tragacanth, about 0.5 per cent. w/v, with spirit of chloroform, tincture of tolu, Cologne spirit, glycerin and distilled water.

Mucilago Tragacanthæ, B.P.—(Mucil. Trag.)—Mucilage of Tragacanth. Tragacanth, 1·25 per cent. w/v, with alcohol, in chloroform water. Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

Pasta Tragacanthæ Composita, B.P.C.—(Past. Trag. Co.)—Compound Tragacanth Paste. *Syn.*—Pasta Lubricans; Catheter Lubricant. Tragacanth, 1 per cent. w/v, and boric acid, 3 per cent. w/v, with oil of lavender, glycerin and decoction of chondrus.

Pulvis Tragacanthæ Compositus, B.P.—(Pulv. Trag. Co.)—Compound Powder of Tragacanth. Tragacanth, 15 per cent., and acacia, 20 per cent., with starch and sucrose. Dose.—0·6 to 4 grammes (10 to 60 grains).

TRIETHANOLAMINA

(Triethanolamin.)

Triethanolamine

Triethanolamine, as obtainable in commerce, is a mixture of bases consisting principally of trihydroxytriethylamine, $(\text{CH}_2\cdot\text{CH}_2\cdot\text{OH})_3\text{N}$, together with small proportions of dihydroxydiethylamine and mono-hydroxyethylamine. It may be prepared by the action of ammonia on ethylene chlorhydrin. Triethanolamine occurs as a clear, colourless, syrupy, almost odourless liquid, which is strongly alkaline to litmus, volatilises only slowly at 100° and has a specific gravity of about 1·12. It forms crystalline salts with mineral acids; the hydrochloride is only sparingly soluble in alcohol and, after washing several times with this solvent, melts at about 173° to 174° . Moderately strong solutions in excess of dilute hydrochloric acid yield a copious white precipitate with phosphotungstic acid, a slight precipitate with iodine solution, and no precipitate with Mayer's reagent or solution of platinic chloride. With the higher fatty and olefinic acids it forms salts, such as triethanolamine stearate, which are soluble in water and have the general characters of soaps.

Miscible with water and alcohol; only slightly soluble in ether and benzene.

Uses.—Triethanolamine has the general properties of the aliphatic bases and, on account of its being less volatile, it possesses certain advantages over ammonia and the volatile organic bases. It has been used in toilet preparations as a substitute for ammonia and in combination with fatty and olefinic acids as an emulsifying agent for oils and fats.

TRIETHANOLAMINÆ STEARAS.—Triethanolamine stearate, or ethanolamine stearate, may be prepared by the interaction of triethanolamine and stearic acid, and occurs as a yellowish-brown solid having a wax-like consistence. It is readily soluble in water, and is decomposed by mineral acids, giving a salt of the base and free stearic acid. It forms an excellent emulsifying agent for use in liquid toilet preparations, forming very stable emulsions with fats, oils, paraffins, etc., and is used as an ingredient of creams and polishes to replace the ordinary soaps.

TRINITROPHENOL

(Trinitrophen.)

Trinitrophenol

Synonyms—Acidum Picricum; Picric Acid; Carbazotic Acid.

Trinitrophenol is 2 : 4 : 6-trinitrophenol, $\text{C}_6\text{H}_2(\text{OH})(\text{NO}_2)_3$, and may be obtained by the nitration of phenol. It occurs as a bright yellow, crystalline powder without odour and having a very bitter taste. The aqueous solution has an acid reaction and, unlike phenols, trinitrophenol liberates carbon dioxide from carbonates. The solution has an intensely yellow colour and stains the skin, the colour deepening on the addition of alkali. Trinitrophenol burns readily and explodes if heated rapidly or subjected to percussion. It forms very insoluble compounds with many alkaloids and precipitates proteins in the cold, the precipitate becoming denser on heating. It forms salts with metals, some of which are very explosive, and addition compounds with many polynuclear hydrocarbons, such as naphthalene and anthracene. The sale and storage of trinitrophenol and its derivatives are subject to legal restrictions except in the case of small quantities. It may be **stored** mixed with an equal weight of water.

Soluble in water (about 1 in 90), alcohol (90 per cent.) (about 1 in 10) and ether (1 in 25).

Standard, B.P.—Trinitrophenol contains not less than 99 per cent. of $\text{C}_6\text{H}_3\text{O}_7\text{N}_3$. Melting-point, 121° to 123° (the operator should be protected by a glass screen when making this determination). Residue on extraction with benzene at 50° , not more than 0.1 per cent. It complies also with a limit test for sulphate.

Action and Uses.—Trinitrophenol is an irritant to the skin and mucous membranes. Taken **internally**, it may produce nausea, vomiting and diarrhoea; after absorption it stains the skin and mucous membranes a yellow colour, simulating jaundice. The urine is coloured either yellow or red and may contain casts, blood cells and albumen, but no bile. It has been employed internally in malaria and exophthalmic goitre, and as an antipyretic, but for these purposes it is inferior to other drugs. Occasionally it is used as a bitter tonic in doses of 0.06 gramme (1 grain). It may be administered in the form of a mixture, although its internal administration is not generally to be recommended. **Externally**, a 1 per cent. w/v aqueous solution (Lotio Trinitrophenolis) is applied on absorbent gauze or lint to wounds and burns of the first and second degrees, but should not be applied over large surfaces, since toxic symptoms may arise from absorption. The lotion is also applied to the skin in eczema, erysipelas and other inflammatory conditions. The principal use of trinitrophenol is as an antiseptic for the skin before operations. A 1 to 3 per cent. w/v solution in alcohol or a 1 per cent. w/v solution in water is used for skin sterilisation in practically

the same way as weak solution of iodine. Skin eruptions of a morbilliform type have been observed in a few cases after its use. Trinitrophenol ointment has been applied to the eyes for burns, especially those caused by quicklime. A 5 per cent. w/v solution in alcohol has been recommended for hyperhidrosis of the feet.

Trinitrophenol is used in the form of a saturated aqueous solution as a hardening agent and as a stain in microscopical work, and it is also employed in urine analysis for the detection and determination of glucose, the determination of albumin, and for the detection and determination of creatinine. Recent stains on the skin caused by trinitrophenol may be removed by means of a solution containing 1 per cent. each of boric acid and sodium benzoate or by a paste of magnesium carbonate with water.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Preparations

Carbasus Trinitrophenolis, B.P.C.—(Carbas. Trinitrophen.)—Trinitrophenol Gauze. *Syn.*—Picric Gauze; Picric Acid Gauze. It contains from 1.5 to 2.5 per cent. of trinitrophenol.

Liquor Trinitrophenolis, B.P.C.—(Liq. Trinitrophen.)—Solution of Trinitrophenol. *Syn.*—Liquor Acidi Picrici; Solution of Picric Acid. Trinitrophenol, 5 per cent. w/v, in alcohol (90 per cent.).

Lotio Trinitrophenolis, B.P.C.—(Lot. Trinitrophen.)—Lotion of Trinitrophenol. *Syn.*—Lotio Acidi Picrici; Picric Acid Lotion. Trinitrophenol, 1 per cent. w/v, in distilled water.

Unguentum Trinitrophenolis, B.P.C.—(Ung. Trinitrophen.)—Trinitrophenol Ointment. *Syn.*—Unguentum Acidi Picrici; Picric Acid Ointment. Trinitrophenol, 2 per cent., and distilled water, in yellow soft paraffin.

TRYPARSONUM

(Tryparson.)

Tryparson

Tryparson, $\text{NaO}(\text{OH}) \cdot \text{AsO} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{CONH}_2, \frac{1}{2}\text{H}_2\text{O}$, is sodium N-phenyl glycineamide-*p*-arsonate and may be prepared by boiling an aqueous solution of sodium-*p*-aminophenylarsonate with chloracetamide, converting the resulting N-phenyl-glycineamide-*p*-arsonic acid into its sodium salt and crystallising from dilute alcohol. It is a white, crystalline powder, without odour and stable in air.

Readily **soluble** in water (3 in 10), the aqueous solution being neutral to litmus; insoluble in alcohol.

Standard.—Tryparson contains not less than 25.1 per cent. and not more than 25.5 per cent. of arsenic, and not less than 9.25 per cent. and not more than 9.5 per cent. of nitrogen, both calculated on the substance dried at 105° to 110°. Loss on drying at 105° to 110°, not less than 2.5

per cent. and not more than 3·5 per cent. 1 gramme dissolved in 20 millilitres of water remains clear on the addition of 5 millilitres of magnesium ammonio-sulphate solution in the cold (absence of soluble inorganic arsenates); on heating, a white precipitate is produced. To 0·25 gramme dissolved in 5 millilitres of water add 5 drops of a 10 per cent. w/v solution of sodium nitrite, cool to below 5° and add 5 millilitres of dilute hydrochloric acid followed by a solution of 0·5 gramme of betanaphthol in 10 millilitres of 2N sodium hydroxide; no red colour is produced (absence of arsanilic acid). A solution of 1 gramme in 20 millilitres of water is not darkened by the addition of hydrogen sulphide. It complies also with the test for toxicity.

Assay.—For arsenic. Cautiously heat about 0·2 gramme, accurately weighed, in a 600 millilitre conical flask with 7·5 millilitres of sulphuric acid and 1·5 millilitres of fuming nitric acid for forty-five minutes; add a further 10 to 15 drops of fuming nitric acid and continue heating more strongly for fifteen minutes; cool the solution, add 5 grammes of ammonium sulphate, gently warm the mixture until the reaction ceases, and then dilute to about 60 millilitres with water; add 1 gramme of potassium iodide and boil the solution, carefully avoiding any possible loss owing to spraying, until the liquid assumes a pale straw-colour, add one or two drops of N/10 sodium thiosulphate to render the solution colourless and dilute the solution to about 120 millilitres with water; add 50 millilitres of 4N sodium carbonate, followed by a slight excess of sodium bicarbonate, and titrate the solution with N/10 iodine using starch solution as indicator; each millilitre of N/10 iodine is equivalent to 0·003746 gramme of As.

For nitrogen. Dissolve about 0·3 gramme, accurately weighed, in 30 millilitres of sulphuric acid, add 10 grammes of potassium sulphate and a small globule of mercury and heat the mixture for about eight hours or until colourless; when cold dilute the solution with water to about 250 millilitres, make alkaline by the addition of 10N sodium hydroxide, add 1 millilitre of solution of sodium sulphide, distil the liberated ammonia into 25 millilitres of N/10 sulphuric acid and titrate the solution with N/10 sodium hydroxide, using methyl red as indicator; each millilitre of N/10 sulphuric acid is equivalent to 0·001401 gramme of N.

Test for toxicity.—A dose equivalent to 0·75 gramme per kilogram of body weight, injected intravenously into a rabbit, produces no toxic symptoms.

Action and Uses.—Tryparsone was introduced for the treatment of sleeping sickness (trypanosomiasis) and, because of its value in the nervous manifestations of this disease, its use in syphilitic affections of the nervous system was suggested. There is general agreement that in cases of general paresis and tabes treatment with tryparsone is of considerable value, better results being obtained than with the arsphenamines. It has also been used with considerable success in other forms of neurosyphilis. It may be combined with malarial treatment. It has

been shown to be useless in primary and secondary syphilis, since its administration in these stages appears to have no effect on the spirochætes in the secretion from the various lesions. On account of the liability of the drug to produce optic atrophy, caution should be observed when using it for cases of neurosyphilis with optic involvement.

Tryparsone is preferably **administered** intravenously, although it may be given intramuscularly. If given by the mouth it is less active and may produce diarrhœa and vomiting. In the treatment of neurosyphilis, doses of 2 to 3 grammes (30 to 45 grains) are administered up to a total of 130 grammes or more, usually in courses of eight to ten doses. In cases of trypanosomiasis, if treatment is commenced early, a total of 20 to 40 grammes may suffice to effect a cure, but in chronic cases 50 to 100 grammes may be necessary; it is administered in doses of 3 grammes (45 grains) once a week, in courses of eight injections. It is against *Trypanosoma gambiense* that tryparsone produces its sterilising action. If the infection is due to *Trypanosoma rhodesiense*, tryparsone fails to sterilise either the peripheral blood or the cerebrospinal fluid.

Numerous toxic effects of tryparsone have been described, the chief of which is amaurosis, which may go on to complete blindness. Occasionally vomiting and slowing of the pulse occur immediately after the injection, as is seen in the case of the arspenamines. Vasomotor effects, fever, headache, diarrhœa, vomiting and delirium are sometimes met with. Excretion is rapid in the majority of persons, 90 per cent. of the drug being excreted in the urine within twenty-four hours. Occasionally the excretion may be slower.

Dose.— 0·5 to 3 grammes (8 to 45 grains), by intravenous injection.

TRYPSINUM

(Trypsin.)

Trypsin

Trypsin is a proteolytic enzyme secreted by the pancreas and may be isolated in a state of comparative purity from the fresh and healthy pancreas of the hog. It may also be extracted from pancreatin with alcohol (40 per cent.) acidified with phosphoric acid, by digesting for a few hours, filtering, and precipitating with strong alcohol. These processes do not yield a trypsin free from amylolytic power, nor is any commercial trypsin powder free from amylase.

Trypsin occurs in the form of a whitish or yellowish powder, having a pepsin-like odour. It acts with great rapidity on soluble proteins, such as the casein of milk, but slowly on coagulated egg albumen. The action is best promoted in alkaline solution of from pH 8·0 to pH 9·0 with fibrin or gelatin as a substrate, and at pH 6·0 to pH 6·5 with casein. Its maximum activity is at pH 11·5, but it is rapidly destroyed at this

alkalinity. It is inactive at pH 4.0 although it also exercises its properties in neutral or even faintly acid solution. Its activity, however, ceases at once in a medium having the degree of acidity favourable to peptic action. The temperature most favourable to the action of trypsin lies between 37° and 40°, but above 50° it rapidly diminishes, ceasing altogether at 75°. When in the perfectly dry state, however, the ferment does not lose its activity even after heating to 100°. Pure trypsin has no action on starch or dextrose. Trypsin acts on all soluble and on many insoluble proteins, converting them finally into a mixture of amino-acids and relatively simple polypeptides. Its activity may be determined by the process of the British Pharmacopœia for trypsin in Pancreatinum. It has from 4 to 5 times the proteolytic activity of pancreatin.

Slowly but not completely **soluble** in water; insoluble in alcohol and glycerin.

Action and Uses.—Trypsin has been used internally and externally for its digestive action on protein material, but it is now administered with other pancreatic ferments in the form of pancreatin.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

TUBERCULINUM PRISTINUM

(Tuberculin. *Prist.*)

Old Tuberculin

Old tuberculin is prepared by growing the tubercle bacillus on a fluid medium containing 5 per cent. of glycerin, at approximately 37° for a period of six weeks or more. The growth should be rapid and abundant. The fluid medium, from which the bacilli may or may not have been previously separated by filtration, is then concentrated by evaporation on a water-bath to one-tenth of its original volume, clarified by filtration and diluted, if necessary, with a 50 per cent. v/v aqueous solution of glycerin. If the potency is less than that of the standard preparation, the product is rejected.

Old tuberculin occurs as a transparent, viscous fluid, yellow to brown in colour, having an odour which resembles that of honey. Old tuberculin has the power of causing illness or death when injected parenterally into tuberculous animals. When injected into the skin of tuberculous animals, it produces erythema, induration, or even necrosis, according to the dose injected and the state of sensitivity of the animal. It is practically innocuous to non-tuberculous animals. It possesses a specific toxicity for animals infected with the tubercle bacillus. Old tuberculin is distributed in sterilised glass phials which are sealed so as to exclude bacteria. In the undiluted state it is a very stable reagent and may be kept for months, or even years, at ordinary temperatures without detectable loss of potency. It should, however, as a matter of precaution,

be stored in a cool, dark place; in the diluted state it is unstable and deteriorates at a rate which depends upon the temperature, and dilutions should not be used more than one month after their preparation. When it is prescribed with the suffix T, the old tuberculin dispensed is prepared by growing the human type of bacilli. When the old tuberculin is prescribed with a suffix PT, the old tuberculin dispensed is prepared by growing the bovine type of bacilli. There is, however, no clear evidence that tuberculins prepared from the two types differ as to their active principle.

Standard, B.P.—The potency of old tuberculin is determined by comparing the dose of it necessary to produce its specific toxicity in guinea-pigs or other animals infected with *Bacillus tuberculosis* with the dose of the standard preparation necessary to produce the same effect, as defined in the regulations made under the Therapeutic Substances Act, 1925. It complies also with a test for toxicity and with tests for sterility.

Action and Uses.—Old tuberculin was originally introduced by Koch as a curative agent in the treatment of tuberculosis, but its therapeutic use is not without danger and the consensus of medical opinion appears to be against its efficacy in pulmonary tuberculosis. It is still, however, used in the treatment of tuberculosis of the genito-urinary tract and of tuberculous peritonitis. It is also used as a diagnostic reagent in the tuberculosis of both man and animals. A human being or bovine animal showing significant sensitivity to tuberculin is generally considered to have been infected with the tubercle bacillus, although the infection may not necessarily be active.

Of the several methods which have been employed for performing tuberculin tests in man, those depending upon the development of a skin reaction are now in more general use. In the intradermal method of Mantoux, the tuberculin is injected intradermally. In the Von Pirquet method, the tuberculin is applied to one or more scratches on the skin. In cattle, the test is made by subcutaneous injection, by intradermal injection, or by instillation into the conjunctival sac (Calmette reaction). Owing to the great variation in the sensitivity of man, no exact diagnostic dose can be stated. The intradermal injection of 0·1 millilitre ($1\frac{1}{2}$ minims) of a 1 in 10,000 dilution of old tuberculin is commonly given as an initial test. In the absence of a reaction the test may be repeated, using 0·1 millilitre ($1\frac{1}{2}$ minims) of a 1 in 1000 dilution, and, if still negative, active tuberculosis may be practically excluded. The subcutaneous injection of diluted old tuberculin in small and gradually increasing doses has been used as a means of effecting non-specific desensitisation in some cases of asthma due to allergy.

An ointment containing 50 per cent. of old tuberculin was formerly used for Moro's diagnostic test. Similar ointments containing from 10 to 50 per cent. of old tuberculin have been used therapeutically. In testing cattle, the double intradermal test has largely superseded other methods of testing. 0·1 millilitre ($1\frac{1}{2}$ minims) of undiluted old tuberculin is injected intradermally into a shaved area of the skin of the neck,

or into the skin of the base of the tail. A second injection of 0·1 millilitre ($1\frac{1}{2}$ minims) is made into exactly the same site after an interval of from forty-two to seventy-two hours. A positive reaction is denoted by the development of a hard swelling at the site of injection. In the subcutaneous test for diagnosing tuberculosis in cattle, the old tuberculin is usually diluted 1 in 8 with normal saline solution and the reaction is indicated by a rise in temperature of at least 2°F. above the highest temperature recorded before the injection.

Dose.—Diagnostic, 0·001 to 0·005 millilitre ($\frac{1}{80}$ to $\frac{1}{16}$ minim); therapeutic, 0·000001 millilitre ($\frac{1}{80,000}$ minim), gradually increased.

TURPETHUM

(Turpeth.)

Turpeth

Synonyms—Indian Jalap; Turpethi Radix.

Turpeth consists of the dried root and stem of *Ipomœa Turpethum* R. Br. (Fam. Convolvulaceæ), a twining plant growing in India, Ceylon, the Malay Archipelago and Australia.

Turpeth occurs in cylindrical pieces from 1·5 to 5 centimetres in diameter, but the thicker pieces are often split and deprived of the central portion. Externally, the pieces are greyish-brown in colour and deeply furrowed longitudinally, giving the drug a rope-like appearance. The fracture is short in the bark but fibrous in the wood. The smoothed, transverse surface is light brown, showing in the xylem very large vessels and wide medullary rays containing starch. Resin cells and abnormal wood bundles are found in the bark. The drug has a faint odour and a nauseous taste which is slowly developed.

Turpeth **contains** from 5 to 10 per cent. of resin, part of which is soluble in ether. The ether-soluble resin is a mixture of α - and β -turpethin; the ether-insoluble resin has been called turpethin.

Action and Uses.—Turpeth has properties resembling those of jalap, but is slower in its action and rather less powerful. It is used in India and the Eastern Colonies in place of jalap.

Dose.—0·3 to 1·2 grammes (5 to 20 grains).

TUSSILAGINIS FLOS

(Tussilag. Flos)

Coltsfoot Flower

Synonym—Farfaræ Flores.

Coltsfoot flower consists of the dried flowering shoots of *Tussilago Farfara* Linn. (Fam. Compositæ), a perennial herb indigenous to

Europe and Central and Northern Asia. The flowers of the coltsfoot appear before the leaves and are collected in the early spring.

The peduncles are simple, about 4 to 15 centimetres long, and bear numerous, linear, entire, reddish bracts up to 1 centimetre long, and cottony hairs each terminating in a small, dark red gland. Each terminal capitulum consists of about 40 central staminate and tubular florets surrounded by about 300 pistillate florets with very narrow, bright yellow, ligulate corollas having rounded apices without teeth. The fruit is crowned with a pappus of colourless, barbed bristles, 3 to 4 cells wide. The flowers are odourless and tasteless. The flowering stems probably **contain** constituents similar to those of the leaves, but the bitter principle present in the leaves is absent from the flowers.

Action and Uses.—Coltsfoot flower has properties similar to those of the leaf and is employed in the preparation of Syrupus Tussilaginis.

Preparations

Extractum Tussilaginis Liquidum, B.P.C.—(Ext. Tussilag. Liq.)—Liquid Extract of Coltsfoot. 1 in 1. Dose.—0·6 to 2 millilitres (10 to 30 minims).

Syrupus Tussilaginis, B.P.C.—(Syr. Tussilag.)—Syrup of Coltsfoot. Liquid extract of coltsfoot, 1 in 4, in syrup. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

TUSSILAGINIS FOLIUM

(Tussilag. Fol.)

Coltsfoot Leaf

Synonym—Farfaræ Folia.

Coltsfoot leaf consists of the dried leaves of *Tussilago Farfara* Linn. (Fam. Compositæ).

The leaves, which appear much later than the flower stems, are cordate, petiolate, and from 10 to 25 centimetres wide. The margin is sinuate-dentate, each tooth terminating in a hard, brown point. The upper surface is greyish-green and wrinkled, the under surface being white with densely tomentose, loose, felted hairs. The leaves are without characteristic odour or taste.

The **microscopical** characters are the wavy-walled and striated epidermal cells; the 3 or 4 rows of palisade cells; the numerous stomata on both surfaces; the abundant, characteristic, slender, whip-like, uniseriate hairs, each composed of 3 to 6 short cells and a very narrow terminal cell which often attains a length of about 0·8 millimetre. The leaves **contain** mucilage, tannin and traces of a bitter glycoside.

Substitutes.—The leaves of butterbur, *Tussilago Petasites* Linn., may be distinguished by their more rounded outline, larger size and less sinuate margin.

Action and Uses.—Coltsfoot leaf is used as a demulcent to relieve chronic and irritable cough. A decoction (1 in 20) may be taken in doses of 2 fluid ounces, or more, several times daily.

ULMUS FULVA

(Ulm. Fulv.)

Slippery Elm

Slippery elm is the dried bark, deprived of the dark outer portion, of *Ulmus fulva* Michaux (Fam. Ulmaceæ), a small tree indigenous to the Central and Northern United States of America.

The bark occurs in large, flat strips, several decimetres in length but only about 3 millimetres thick, consisting of secondary phloem. The outer surface is reddish-brown with patches of the brown outer portion, and longitudinally striated; the inner surface is tawny yellow. The bark is very tough and fibrous. The smoothed, transverse section is minutely chequered, due to tangentially alternating layers of bast fibres and sieve tissue traversed by medullary rays, and, after moistening, exhibits numerous cells filled with transparent, swollen mucilage. The odour is strong, resembling fœnugreek, and the taste is very mucilaginous.

The diagnostic **microscopical** characters are the large mucilage cells scattered throughout the phloem and staining with ruthenium red; the groups of only slightly lignified, but strongly thickened, phloem fibres, surrounded by cells containing prisms of calcium oxalate; the numerous starch grains, usually 3 to 5 microns wide but sometimes up to 25 microns; the absence of stone cells and of cork.

Slippery elm **contains** mucilage; 10 grains of the powdered bark will convert one fluid ounce of cold water into a thick jelly. It also contains a little tannin.

Standard.—Slippery elm yields not more than 12 per cent. of ash. Acid-insoluble ash not more than 0.4 per cent.

Slippery elm, in powder (Pulvis Ulmi Fulvæ: Pulv. Ulm. Fulv.), contains the constituents and possesses the diagnostic microscopical characters of *Ulmus Fulva*, and complies with the standard for the unground drug.

Action and Uses.—Slippery elm is used in the form of decoction (1 in 8) as a demulcent in catarrhal affections and in diarrhœa and dysentery. It is sometimes mixed with hot water for use as a poultice for ulcers and whitlows. An enema prepared by adding boiling water to slippery elm (1 in 20) has been used for inflammation of the bowel.

URANII NITRAS

(Uran. Nit.)

Uranium Nitrate

Synonyms—Uranyl Nitrate; Uranic Nitrate.

Uranium nitrate may be prepared from pitch-blende by treating the finely powdered mineral with concentrated nitric acid and removing from the solution by appropriate treatment the various other metals

associated with it, such as barium, bismuth, lead, iron, zinc, radium and polonium. The purified solution finally obtained is evaporated and the salt crystallised. It occurs in the form of odourless, lemon-yellow, rhombic prisms, greenish-yellow by reflected light, superficially efflorescent in dry air and having radioactive properties. The solutions have a bitter, astringent, styptic taste, without any metallic after-taste. It melts in its water of crystallisation at 59.5° , and the liquid boils at 118° . On further heating it is decomposed, giving off nitric acid and leaving the reddish-yellow trioxide, UO_3 , and, at a still higher temperature, the dark green oxide, U_3O_8 . It is reduced to the uranous salt by hydrogen sulphide and by alcohol, ether and other organic matter in sunlight.

The radioactivity of uranium nitrate may be shown by placing a crystal on a material impervious to light, such as black paper or aluminium, and laying it on a photographic plate for a short time, when, after developing, the position and shape of the crystal will be recorded, or, if a crystal is held at a short distance from a charged electroscope this will lose its charge more quickly than it would normally. When the salt, however, is recrystallised from ether this property is lost, showing that the activity is due to some other substance ordinarily present. It should be stored in well-stoppered bottles and protected from light.

Readily **soluble** in water (about 2 in 1); soluble in alcohol and ether.

Standard.—Uranium nitrate contains not less than 98 per cent. of $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$. 1 gramme complies with the limit test for sulphates. The aqueous solution (1 in 20) is not turbid, and remains clear on the addition of an equal volume of ammonium carbonate solution (limit of alkaline earths); on diluting this solution and saturating it with hydrogen sulphide, no darkening or precipitate is produced (limit of lead, iron, manganese and zinc). 1 gramme dissolved in 20 millilitres of water and acidified with dilute sulphuric acid does not completely decolourise 0.1 millilitre of N/10 potassium permanganate (limit of uranous compounds).

Assay.—Dissolve about 0.5 gramme, accurately weighed, in 100 millilitres of water, boil and add excess of solution of ammonia; wash the precipitate on a filter with 1 per cent. w/v ammonium nitrate solution, and ignite; 1 gramme of the residue, U_3O_8 , is equivalent to 1.789 grammes of $\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$.

Action and Uses.—Solutions of uranium nitrate are poisonous and produce glycosuria when injected subcutaneously, even in small doses. They should be used with the greatest caution since they very easily cause nephritis. The action of uranium salts in producing glycosuria is attributed to increased permeability of the renal cells to sugar, since there is no increase of sugar in the blood. They have been employed internally in diabetes and cancer, but there is little or no ground for attributing to them any beneficial action in these diseases. Uranium nitrate is best administered in dilute solution in mixture form.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

URANII ACETAS.—Uranium acetate, $\text{UO}_2(\text{CH}_3\text{CO}_2)_2 \cdot 2\text{H}_2\text{O}$, occurs in the form of yellow, transparent, rhombic crystals. It is used as a reagent to detect peroxides; on the addition of hydrogen peroxide and then potassium carbonate, a red colour is produced; on adding two or three times its volume of alcohol, a heavy red precipitate is obtained. Zinc uranyl acetate is used as a reagent for the quantitative determination of sodium.

UREA

(Urea)

Urea

Synonym—Carbamide.

Urea, $\text{CO}(\text{NH}_2)_2$, is the diamide of carbonic acid, and may be obtained by the direct condensation of ammonia and carbon dioxide under pressure. It is present in urine to the extent of about 2.5 to 3 per cent. Urea occurs in the form of colourless, transparent, prismatic crystals which are somewhat hygroscopic, almost odourless and have a cooling, saline taste. It combines with acids to form mono-acid salts, of which the best known are the nitrate, $\text{CH}_4\text{ON}_2 \cdot \text{HNO}_3$, and oxalate, $(\text{CH}_4\text{ON}_2)_2 \cdot \text{H}_2\text{C}_2\text{O}_4$. The former is precipitated on adding excess of nitric acid to an aqueous solution of urea; it is soluble in water but insoluble in nitric acid. The oxalate is sparingly soluble in water. Both salts crystallise in characteristic forms.

When heated above the melting-point urea is decomposed; at 150° ammonia is evolved and biuret, $\text{NH}(\text{CONH}_2)_2$, remains, which can be identified by dissolving the product in water, making the solution alkaline with sodium hydroxide solution and adding one drop of copper sulphate solution, when a reddish-violet colour is produced. At higher temperatures biuret is decomposed into ammonia and cyanuric acid. When urea is heated with water under pressure, ammonium carbonate is formed.

Soluble in water (1 in 1), alcohol (90 per cent.) (1 in 5) and boiling alcohol (90 per cent.) (1 in 1); insoluble in ether and chloroform.

Standard, B.P.—Urea has a melting-point of 130° to 132° . Ash, not more than 0.1 per cent.

Action and Uses.—Urea is non-toxic and exerts a diuretic action which probably depends upon its power to increase the proportion of units functioning in the kidney. The renal threshold for urea is low; excretion is rapid and is accompanied by an increase in the output of urine. The ability to excrete urea is markedly impaired when renal damage has occurred, as in chronic interstitial nephritis. Urea is formed in the liver from ammonium salts. The impairment of the power of the diseased kidney to concentrate urea is extensively used as a test of renal function.

The urea concentration test consists in the administration of 15 grammes of urea dissolved in 100 millilitres of water. The draught is given fasting and after the bladder has been emptied. Determinations

of the urea content of the urine are made one, two and three hours after the dose. At one of these periods the urea content should exceed 2 per cent. A figure below this indicates renal inadequacy unless there is excessive diuresis. The normal urea content of the blood is from 20 to 40 milligrams per 100 millilitres. A figure of 100 milligrams or over indicates uræmia. Urea may be administered by the mouth, or by subcutaneous or intravenous injection. For intravenous administration it should be dissolved in normal saline solution.

Dose.—1 to 16 grammes ($\frac{1}{4}$ to 4 drachms).

ACIDUM URICUM.—Uric acid, $C_5H_4O_3N_4$, is 2:6:8-trioxypurine, and may be obtained from guano or from serpents' excrement. It occurs in white, odourless and tasteless crystals which are decomposed without melting when heated. When a small quantity is mixed with nitric acid and the mixture evaporated to dryness, a yellow residue is left, which changes to violet on the addition of ammonia (murexide test). It is slightly soluble in water, soluble in concentrated sulphuric acid and reprecipitated on dilution with water, and insoluble in alcohol and ether. Uric acid is the chief end-product of purine metabolism in man. The proportion of uric acid in the blood is increased in gout and in advanced chronic interstitial nephritis. Uric acid is non-toxic. It is not used therapeutically.

URETHANUM

(Urethan.)

Urethane

Synonym—Ethyl Carbamate.

Urethane, $CO(NH_2)OC_2H_5$, may be prepared by the action of ammonia upon ethylchloroformate. It occurs in the form of colourless, odourless, prismatic crystals or scales, having a cooling, saline, slightly bitter taste. Its solutions are neutral. Boiling-point, about 180° , subliming without decomposition. It burns with a slightly luminous, bluish flame. When boiled with potassium hydroxide solution, it yields potassium carbonate, alcohol and ammonia. Heated with ammonia, it gives alcohol and urea. On gently heating with five times its weight of sulphuric acid, carbon dioxide is evolved, alcohol and ammonium acid sulphate being formed at the same time. When a solution of 0.5 gramme in 5 millilitres of water is warmed with 1 gramme of sodium carbonate and 0.01 gramme of iodine, crystalline scales of iodoform separate on cooling.

Soluble in water (1 in 2), alcohol (1 in 1), ether, chloroform, glycerin and oils.

Standard.—Urethane melts between 47.5° and 50° . Ash, not more than 0.05 per cent. 1 gramme complies with the limit test for chlorides.

Action and Uses.—Urethane is a safe hypnotic and is particularly useful for administration to children, since it produces light sleep without after-effects and has no depressant action on the heart. It is, however, too weak and inconstant in its action to be successfully employed in the

treatment of insomnia in adults. Urethane is antagonistic to strychnine and in cases of poisoning by this drug, or in tetanus, it may be administered in large doses until the convulsions are controlled. It is oxidised in the body to urea and, therefore, acts as a diuretic. It is used with quinine hydrochloride in *Injectio Quininæ et Urethani* for the injection treatment of varicose veins. Preparations of urethane and quinine for **injection** may be sterilised by heating in an autoclave at 110° for twenty minutes, by tyndallisation, by filtration, or by heating at 100° for thirty minutes.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparation

Injectio Quininæ et Urethani, B.P.C.—(Inj. Quinin. et Urethan.)—Injection of Quinine and Urethane. A sterile aqueous solution containing quinine hydrochloride, about 13·5 per cent. w/v, and urethane, about 6·5 per cent. w/v. **Dose.**—5 millilitres (75 minims), by intravenous injection.

URGINEA

(Urgin.)

Urginea

Synonym—Indian Squill.

Urginea consists of the sliced younger bulbs of *Urginea indica* Kunth. (Fam. Liliaceæ), a plant indigenous to India. The bulbs are collected soon after the plant has flowered, divested of their dry, outer, membranous coats, cut into slices and dried. Urginea should be stored in a cool place and the powdered drug should be kept over quicklime.

The drug occurs in curved or irregularly shaped strips. They are ridged in the direction of their length and vary in colour from pale yellowish-brown to buff. When dry they are brittle, but in the presence of moisture they become tough and flexible. The drug is without odour, but has a bitter taste. Urginea **contains** bitter principles similar to the glycosidal substances found in European squill.

Action and Uses.—Urginea is used in India and the Eastern Colonies in place of squill. Vinegar (Acetum Urginæ), oxymel (Oxymel Urginæ), pill (Pilula Urginæ Composita), syrup (Syrupus Urginæ) and tincture (Tinctura Urginæ), may be prepared and administered in the same way as the corresponding preparations of squill.

UVA URSI

(Uva Ursi)

Bearberry

Synonyms—Uvæ Ursi Folia; Bearberry Leaves.

Bearberry consists of the dried leaves of *Arctostaphylos Uva-ursi* Spreng. (Fam. Ericaceæ), a small, procumbent, evergreen shrub

growing on rather dry, heathy or rocky hills and widely distributed over the greater part of the Northern Hemisphere.

The leaves are dark green or brownish-green in colour, obovate or spatulate, entire, very shortly petiolate, and up to about 3 centimetres in length; they are brittle, coriaceous, and glabrous except near the base and on the petiole. The upper surface is tessellated by sunken veinlets. They are odourless, and the taste is astringent and somewhat bitter.

The diagnostic **microscopical** characters are the epidermis of straight-walled, polygonal cells; the stomata, on the lower surface only, up to 50 microns long and surrounded by 4 to 7 cells; the irregular, prismatic crystals of calcium oxalate enclosed in the cortical collenchyma; the palisade, 3 to 5 rows deep; the small oil drops in most of the cells.

Bearberry **contains** tannin (6 to 7 per cent.), gallic acid, ellagic acid, arbutin, methylarbutin, ursone, quercetin, and probably also myricetin. Arbutin, $C_{12}H_{16}O_7 \cdot \frac{1}{2}H_2O$, melting-point about 168° , is a crystalline glycoside yielding on hydrolysis dextrose and hydroquinone. Ursone, $C_{38}H_{48}O_3 \cdot 2H_2O$, crystallises in colourless, tasteless, odourless needles melting at about 265° .

Substitutes.—The leaves of the box, *Buxus sempervirens* Linn. (Fam. Euphorbiaceæ), and of the cowberry, *Vaccinium Vitis-Idea* Linn. (Fam. Ericaceæ), have been mistaken for bearberry leaves. Box leaves are distinguished by the emarginate apex and easily-separable epidermis, and cowberry leaves by the scattered brown spots on the under surface.

Standard.—Bearberry contains not more than 5 per cent. of foreign organic matter.

Bearberry, in powder (Pulvis Uvæ Ursi: Pulv. Uvæ Ursi), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—Bearberry is diuretic and astringent. Its diuretic action is due to the glycoside, arbutin, which is largely absorbed unchanged and is excreted by the kidneys. A proportion of arbutin is, however, hydrolysed, with formation of hydroquinone; this is also excreted in the urine, to which it gives a greenish-brown colour, darkening on standing owing to oxidation. During its excretion, arbutin exercises an antiseptic effect on the mucous membrane of the urinary tract. Bearberry is, therefore, used in inflammatory diseases such as urethritis, cystitis, etc. It is usually **administered** in the form of infusion, with other diuretics and urinary antiseptics.

Preparations

Infusum Uvæ Ursi Concentratum, B.P.C.—(Inf. Uvæ Ursi Conc.)—Concentrated Infusion of Bearberry. 1 in $2\frac{1}{2}$. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of bearberry, and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Infusum Uvæ Ursi Recens, B.P.C.—(Inf. Uvæ Ursi Rec.)—Fresh Infusion of Bearberry. 1 in 20. When infusion of bearberry or Infusum Uvæ Ursi is prescribed, fresh infusion not being specified, either Infusum Uvæ Ursi Recens or Infusum Uvæ Ursi Concentratum suitably diluted may be dispensed. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

This infusion was included in the British Pharmacopœia, 1914, under the name of Infusum Uvæ Ursi.

VACCINUM BUBONICUM

(Vaccin. Bubonic.)

Anti-plague Vaccine

Anti-plague vaccine is a suspension of a killed culture of *Pasteurella pestis* and contains 0·5 per cent. of phenol as a preservative. The cultures may be grown on solid media at 37°; at this temperature the bacillus develops an envelope which contains an antigen quite distinct from that in the body of the bacillus. The bacilli are then suspended in physiological solution of sodium chloride and killed by heating at 60°, and the suspension is diluted so that the required dose is contained in a convenient volume. Such vaccines are more potent and less toxic than those grown at 26°. It is issued in containers sealed so as to exclude bacteria and should be **stored** in a cool place. The label on the container states the number of organisms per millilitre and the date after which the preparation is not intended to be used.

Standard.—Anti-plague vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Anti-plague vaccine is used as a prophylactic against plague. The usual dose for adults is 1000 million organisms, followed in ten days time by 2000 million, or two doses of 1500 million organisms are given at the same interval. The injection of this vaccine may sometimes give rise to local swelling and redness, and to enlargement of the lymphatic glands. There may also be headache, pyrexia and general malaise. These symptoms usually subside after twenty-four to forty-eight hours. Persons exposed to infection should be inoculated every six months.

HAFFKINE'S PLAGUE PROPHYLACTIC, which is largely used in India, is prepared as follows:—A strain of *P. pestis* is isolated by blood culture from a human case of plague with septicæmia, and maintained in continuous passage in susceptible rats without intermediate culture on artificial media. The strain should be of such a virulence that a dose of 5 to 10 organisms should prove fatal to a white mouse. In order to obtain a pure colony of *P. pestis*, sub-cultures are made on rabbit blood agar which is seeded into acid digest broth (prepared by digesting lean goat flesh in hydrochloric acid for three days and neutralising with sodium hydroxide), standardised to contain 230 milligrams of nitrogen per 100 millilitres and adjusted to pH 6·8. After four days at room temperature, the cultures are incubated for four weeks at 27°. The cultures are then tested for freedom from other organisms and sterilised by heating at 55° for fifteen minutes, 5 grammes of phenol being added to each litre of culture. The vaccine is not standardised, the regularity of the process of manufacture being depended upon for the production of a vaccine of uniform composition. The dose of Haffkine's plague prophylactic is 4 millilitres for adults, unless it is used within three months of the date of manufacture, when the dose is 3 millilitres only.

VACCINUM GONOCOCCICUM

(Vaccin. Gonococcic.)

Gonococcus Vaccine

Gonococcus vaccine is a sterile suspension of numerous strains of *Gonococcus*, prepared from freshly isolated cultures of the organisms. The cultures are separated and suspended in physiological sodium chloride solution, killed by heating at 55° for one hour and, after enumeration, diluted with physiological sodium chloride solution to a degree suitable for the required dosage. It contains 0·5 per cent. of phenol or other equivalent antiseptic, and should be **stored** in sterilised containers sealed so as to exclude bacteria, and should not be used later than three years after the date of its preparation.

Standard.—Gonococcus vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Gonococcus vaccine is used in the treatment of gonorrhœa. In the acute stage the vaccine is useful only if the patient is subjected to a strict routine of diet and rest, and then only in small doses of 2 to 5 million. Small doses are used also in gonococcal arthritis, vulvo-vaginitis of children and gonococcal iritis and ophthalmia. In the treatment of chronic gonorrhœa and gleet larger doses of 100 to 500 million may be given, but as in these conditions there are usually large numbers of streptococci, staphylococci and diphtheroid bacilli present in the discharge, it is often advantageous to use a compound vaccine containing these organisms in addition to the gonococcus. In the treatment of gonorrhœal infections an autogenous vaccine is preferable to a stock vaccine. A dose of gonococcus vaccine equivalent to 500 million organisms may be given as a provocative test dose to indicate whether the patient has been cured; if gonococcal infection persists there is usually a transient discharge in which gonococci may be found.

Dose.—2 million to 500 million organisms, by subcutaneous injection.

VACCINUM PERTUSSIS

(Vaccin. Pertuss.)

Pertussis Vaccine

Synonym—Whooping Cough Vaccine.

Pertussis vaccine is a sterile suspension of *Bacillus pertussis* (*Hæmophilus pertussis*) made from freshly isolated cultures or from cultures preserved in such a way as to retain their antigenic powers. The killed organisms, suspended in physiological sodium chloride solution, are, after enumeration, diluted with physiological sodium chloride solution to a degree suitable for the required dosage. It contains 0·5 per cent. of phenol or other equivalent antiseptic, and should be **stored** in sterilised containers sealed so as to exclude bacteria, and

should not be used later than three years after the date of its preparation. It is important to make the vaccine as soon as possible after the isolation of the cultures. Old stock cultures are unsuitable since in these the antigenic characters of the bacillus are usually altered. Fresh blood agar is a suitable medium on which to grow the cultures in order to maintain maximum antigenic activity.

Standard.—Pertussis vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Pertussis vaccine is used for the prevention and treatment of whooping cough. The reported results of the value of the vaccine are conflicting and it appears that failures in the past have been due to the use of vaccine prepared from old stock cultures which have lost their immunising properties. Inoculation with a vaccine made from a freshly isolated culture of *B. pertussis* confers some immunity against an attack of whooping cough; when an inoculated person contracts the disease the severity of the attack is diminished. Inoculation of contacts with the vaccine is useful for controlling the spread of an epidemic. In the treatment of whooping cough, there is a certain amount of evidence to indicate that the use of vaccine in the early stages of infection shortens the attack. Since the *Bacillus influenzae* and the *Pneumococcus* are frequent secondary invaders, a mixed vaccine containing these organisms as well as the *B. pertussis* is often used for either prophylaxis or treatment. When pertussis vaccine is used as a prophylactic, a child between one and two years of age may receive 800 million, 1600 million and 3200 million organisms at intervals of three or four days; older or younger children should receive doses in proportion to age. For therapeutic purposes, treatment may be commenced with a dose of 250 million, gradually increased. Pertussis vaccine gives little reaction and doses of up to 4000 or even 5000 million organisms can be given safely to children.

VACCINUM PNEUMOCOCCICUM

(Vaccin. Pneumococcic.)

Pneumococcus Vaccine

Pneumococcus vaccine is a suspension of killed pneumococci isolated from pneumococcal infections in man. The genus *Pneumococcus* exhibits three serological groups—types I, II and III; and a heterogeneous group, comprising all those which do not conform to any of the other three types, is termed type IV. The vaccine is prepared by growing the organisms on a suitable culture medium at 37° and, when satisfactory growth is obtained, washing off the culture, suspending it in physiological saline solution and enumerating by a suitable method. The organisms are killed by heating at 57° for one or two hours. The suspension is diluted to contain the required number of organisms in a volume suitable for dosage, and a preservative equivalent to 0.5 per

cent. of phenol is added. Stock pneumococcus vaccine is usually prepared from a mixture of all four types of the pneumococcus, but when the infecting type can be determined a monotypical autogenous vaccine may be used in preference to a stock vaccine. It should be **stored** in sterilised containers sealed so as to exclude bacteria and should not be used later than three years after the date of its preparation.

Standard.—Pneumococcus vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Pneumococcus vaccine is employed in chronic and subacute localised infections due to the pneumococcus, such as empyema, arthritis, sinusitis, abscesses, etc. It is also used in the treatment of acute pneumococcal lobar pneumonia or broncho-pneumonia; it is said that an attack can be aborted if the vaccine is given in the incubation stage. The vaccine may be given as a prophylactic to protect susceptible persons who are exposed to pneumococcal infections. Pneumococcus vaccine has also been used with varying success in the treatment of chronic bronchial and nasal catarrh due to this organism. Frequently other organisms are present in these conditions, giving rise to mixed infections. These ancillary organisms are chiefly *B. influenzae*, staphylococci, streptococci and gram-negative cocci of the catarrhalis group. In these mixed infections mixed vaccines should be employed. The dose of pneumococcus vaccine in chronic infections is from 25 to 50 million organisms injected subcutaneously, followed, at intervals of five to seven days, by increasing doses up to a maximum of 2000 million. The aim of dosage is to build up a rapid immunity without causing focal reactions. For prophylaxis, doses of 500, 1000 and 2000 million may be given at intervals of seven days. In acute lobar pneumonia, the dose should not exceed 5 million and may be doubled after twenty-four hours.

INFLUENZA VACCINE.—Vaccines prepared from bacteria associated with influenza are used for the prevention and treatment of epidemic influenza. The common bacteria associated with severe influenza are the *B. influenzae*, pneumococci, and streptococci, and these are usually incorporated in one vaccine. It is important to use as many different, freshly isolated strains of *B. influenzae* as possible in the preparation of the vaccine. It is improbable that the immunity from such a vaccine persists longer than three months. There is strong evidence to indicate that the primary infection in influenza is a filter-passing virus, and that the *B. influenzae* and other bacteria are merely secondary factors. Influenza vaccine may be administered in doses of 500 or 1000 million of the organism, *B. influenzae*, together with 1000 million pneumococci and 100 million streptococci.

VACCINUM STAPHYLOCOCCICUM

(Vaccin. Staphylococcic.)

Staphylococcus Vaccine

Staphylococcus vaccine is a sterile suspension of killed staphylococci. The genus *Staphylococcus* comprises two main chromogenic

types, the white and the golden-yellow staphylococcus, respectively known as *Staphylococcus albus* and *Staphylococcus aureus*. As a general rule, the aureus strains are the more virulent and they are more commonly encountered in human lesions. Staphylococcus vaccine contains both chromogenic types, but *S. aureus* predominates. It is prepared by growing the organisms on a suitable culture medium for twenty-four hours, after which they are suspended in physiological sodium chloride solution containing 0.5 per cent. of phenol and killed by heating at 65°. The number of organisms in the suspension is estimated by an appropriate method and the suspension diluted, to a degree convenient for the required dosage, with physiological sodium chloride solution containing 0.5 per cent. of phenol. It is issued in containers sealed so as to exclude bacteria and should be **stored** between 0° and 15°. The label on the container indicates the number of organisms per millilitre.

Standard.—Staphylococcus vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Staphylococcus vaccine is of proved value in the treatment of staphylococcal infections of the skin, such as pustular acne, sycosis, impetigo, furunculosis and carbuncles. It is also of value in the treatment of osteomyelitis, as an adjunct to operative measures, and for the prophylaxis of infection after wounds or surgical operations. When the vaccine is used for the treatment of staphylococcal infections in an adult, the first dose should be 25 to 100 million injected subcutaneously, increasing the dosage by regular increments, at intervals of five to seven days, up to a maximum dose of 1000 to 2000 million organisms. In very severe infections, such as osteomyelitis, doses of 5 million organisms may be repeated at intervals of twenty-four hours. For children, the doses for treatment should be from one-quarter to one-sixth of the adult dose, depending upon the age and clinical condition of the child. The prophylactic doses for both adults and children are 500 and 1000 million at an interval of a week.

Dose.—5 to 2000 million organisms, by subcutaneous injection.

ACNE BACILLUS VACCINE is a suspension of killed acne bacilli in sterile normal saline solution containing 0.5 per cent. of phenol. It is used in the treatment of acne vulgaris, often in association with staphylococcus vaccine. Usually a prolonged course of treatment is necessary before much improvement is evident. The initial dose of acne bacillus vaccine is 5 million organisms, gradually increased. In some cases, doses from 100 million to 2000 million may be necessary. In cases of pustular acne, staphylococcus vaccine in doses of from 200 million to 2000 million may be given in addition to acne bacillus vaccine.

ANTITOXINUM STAPHYLOCOCCICUM.—Staphylococcus antitoxin is prepared from the serum of horses which have been immunised by repeated injections of the specific toxin of the *Staphylococcus*. The potency of the antitoxin can be determined against the specific toxin by means of a skin test on rabbits. The antitoxin complies with the regulations made under the Therapeutic Substances Act, 1925. It is used in the treatment of furunculosis, staphylococcal septicæmia and acute osteomyelitis.

BACILLUS COLI VACCINE is used in the treatment of *B. coli* infections of the genito-urinary tract. The dose ranges from 5 million, increased at weekly intervals to 500 million. The vaccine is sometimes administered to patients suffering from *B. coli* infection of the urinary tract to immunise them preparatory to a major operation on that region. Three doses should be given, 100, 500 and 1000 million at weekly intervals.

VACCINUM STREPTOCOCCICUM.—*Streptococcus* vaccine is a suspension of killed cultures of various strains of *Streptococcus*, and is prepared by methods similar to those used for other vaccines. The streptococci are a large group of organisms associated with a great variety of infections, and the selection of strains of the organism for the preparation of the vaccine depends upon the condition it is desired to treat. No entirely satisfactory system of classification of the streptococci has yet been evolved; they may be broadly grouped by their action when grown on blood agar into *Streptococcus hæmolyticus*, which in its growth dissolves red blood cells, *Streptococcus viridans*, which changes hæmoglobin into methæmoglobin, thus changing the red colour of blood to green, and an indifferent group which has no action on blood. They may also be classified roughly according to the region of the body which they usually inhabit or by their pathogenic action. For the treatment of chronic rheumatic conditions a vaccine composed of numerous strains of streptococci isolated from the mouth, intestines and genito-urinary tract of patients suffering from rheumatism is employed. It is most useful in the non-arthritic types of rheumatism. The dose may range from an initial dose of $\frac{1}{2}$ to 1 million streptococci up to 500 or 1000 million streptococci. In acute rheumatic conditions the vaccine is sometimes injected intravenously in doses of 1 million, gradually increased up to 100 million.

Other conditions for which streptococcus vaccine is employed are cellulitis, septic burns and septic wounds (often in conjunction with staphylococcus vaccine), mouth infections such as pyorrhæa alveolaris, and streptococcal infections of the intestinal tract. In acute streptococcal infections, such as scarlet fever, puerperal septicæmia and erysipelas, streptococcus antitoxin (scarlatina) is more generally used.

VACCINUM TUBERCULINUM

(Vaccin. Tuberculin.)

Tubercle Vaccine

Tubercle vaccine is prepared by the prolonged grinding in a ball mill of living tubercle bacilli grown on a solid medium. The grinding, which may occupy several months, is continued until all the bacilli are dead and have lost their acid-fast properties. The material is then emulsified in normal saline solution and so diluted that the number of milligrams of solid material is convenient for human dosage. It is now often prepared by grinding heat-killed tubercle bacilli in the same way. Tubercle vaccine appears to contain the same active principle as old tuberculin but, as tested by animal methods, its potency is usually not more than one-tenth to one-twentieth that of the standard preparation of old tuberculin. It is issued in containers sealed so as to exclude bacteria, and should be **stored** between 0° and 15°. The label on the container indicates the weight in milligrams of powdered tubercle bacilli per millilitre.

Standard.—Tubercle vaccine complies with the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Tubercle vaccine is used in the treatment of localised tuberculous infections, for example, tuberculous glands, tuberculous of the bones and joints, tuberculous cystitis and lupus. Caution should be observed in its use, particularly in the treatment of pulmonary tuberculosis. Owing to the great variation in the sensitivity of patients, no exact system of dosage can be laid down. It is advisable to commence treatment with the subcutaneous injection of not more than the equivalent of ४००.००० to १००.००० milligram of dried substance, increasing the dose cautiously at five to seven day intervals if well tolerated. Tubercle vaccine is not suitable for diagnostic purposes.

TUBERCULINUM NOVUM.—Under the name “new tuberculin” are grouped a number of preparations which are prepared by methods which aim at releasing the endocellular material of tubercle bacilli. Thus, while old tuberculin is a filtrate of a fluid medium upon which *Bacillus tuberculosis* has grown, new tuberculin consists of preparations made from the disintegrated bodies of the bacilli. Tubercle vaccine, also called tuberculin bacillary emulsion (T.B.E.) is the preparation to which the name “new tuberculin” was originally applied by Koch. Other preparations of a similar nature are designated under the names T.R. (German-Tuberkulin-Ruckstand) and P.B.E. (German-Perlsuchtbazillenemulsion). These preparations were introduced for the treatment of tuberculosis, but in spite of long experience in their use there is little evidence that they have any therapeutic or prophylactic value, and they are unsuitable for diagnostic use.

VACCINUM TYPHO-PARATYPHOSUM

(Vaccin. Typho-paratyphos.)

Anti-typhoid-paratyphoid Vaccine

Synonym—T. A. B. Vaccine.

Anti-typhoid-paratyphoid vaccine is a sterile suspension of killed organisms, *Bacillus typhosus*, *B. paratyphosus A* and *B. paratyphosus B*. It is prepared from pure cultures of each of the three organisms, which are grown separately for twenty-four hours on solid media, and then suspended in physiological solution of sodium chloride. The suspensions are heated at 55° for one hour to kill the organisms, enumerated by a suitable method, and mixed in such proportions as to produce a suspension containing the required number of organisms per millilitre. It contains 0.5 per cent. of phenol or other equally effective antiseptic. It should be **stored** between 0° and 15° in sterilised containers sealed so as to exclude bacteria, and should not be used later than eighteen months after the date of its preparation.

Standard, B.P.—Each millilitre of anti-typhoid-paratyphoid vaccine contains 1000 million *B. typhosus*, 500 million *B. paratyphosus A*, and 500 million *B. paratyphosus B*. It complies with the tests for sterility prescribed in the regulations made under the Therapeutic Substances Act, 1925.

Action and Uses.—Anti-typhoid-paratyphoid vaccine is used for the prevention of typhoid and paratyphoid fevers. Persons should be inoculated before proceeding to a country where typhoid is endemic, and not during an epidemic. The duration of immunity is probably not more than two years and may be even less.

Dilutions of anti-typhoid-paratyphoid vaccine have been used for intravenous injection to provoke general systemic reactions in the treatment of disseminated sclerosis, rheumatoid arthritis, general paralysis, tertiary syphilis and certain eye diseases, such as severe, acute and sub-acute infections of the conjunctiva, ulcers of the cornea and keratitis. For this purpose the initial dose should be from 25 to 100 million organisms, diluted to 5 millilitres with normal saline solution. Subsequently the dose is increased at intervals of four or five days to a maximum of 500 million or more.

Dose.—Prophylactic, 0.5 millilitre (first dose) to 1 millilitre (second dose after seven to ten days), by subcutaneous injection.

VACCINUM CHOLERÆ.—Cholera vaccine is prepared from twenty-four-hour cultures of the *Vibrio cholerae*, which are killed by heating at 56° and suspended in normal saline solution containing 0.5 per cent. of phenol. It is used for prophylactic inoculation against cholera, often together with anti-typhoid-paratyphoid vaccine as a compound vaccine (T.A.B.C. Vaccine). Dose.—1000 million organisms, followed after seven or ten days by 2000 million.

VACCINUM VACCINIÆ

(Vaccin. Vacciniæ)

Vaccine Lymph

Synonym—Vaccinum Antivariolum.

Vaccine lymph is a preparation of the substance obtained from the vesicles produced on the skin of healthy animals, usually calves, by the cutaneous inoculation of vaccinia virus. Calves which appear to be healthy and from three to six months old, are kept under observation for approximately one week in specially constructed premises so arranged that they can be kept scrupulously clean. The animals are thoroughly cleaned and groomed, and their temperatures systematically taken and recorded; any sick or doubtful animal is at once rejected.

The skin over the abdomen and flanks is shaved and washed thoroughly with soap and hot water, then with sterilised water and dried with sterilised swabs. Light incisions are made in the cleansed skin without, as far as possible, drawing blood, and on them stock vaccine lymph of ensured potency is implanted. The calves are then removed to other premises and carefully watched. Five days later, if the vesicular development is good, the site of vaccination is washed and dried as before, and the contents of the vesicles (the pulp) are removed, under aseptic conditions, by means of a Volkmann's spoon. The pulp from each animal is collected separately and the containers labelled. The animals are then removed from the premises, slaughtered,

and the carcasses examined by a veterinary surgeon. Unless the animal is certified to be completely free from disease, the pulp from it is forthwith destroyed. The pulp or crude lymph is weighed, and after thorough grinding is mixed with four times its weight of 50 per cent. glycerin in distilled water, or some other partial disinfectant. It is then maintained at temperatures below 0° until, by the action of the disinfectant and of the low temperature, the number of living bacteria and other organisms is reduced to the required limit.

Vaccine lymph occurs as a viscid, colourless liquid, containing white particles in suspension. It should be **stored** in sterilised glass containers sealed so as to exclude bacteria. Each container holds one dose, or in an emergency a container holding several doses may be used. Its potency is retained for long periods when stored below 0°. At temperatures from 0° to 5°, the potency is usually retained for three months; at temperatures from 5° to 10°, it is retained for four weeks. When stored above 10°, the potency may be lost after seven days.

Standard, B.P.—Vaccine lymph contains not more than 5000 living bacteria or other organisms per millilitre. It complies with the test for absence of living, gas-producing, anaerobic organisms, and with the test for absence of hæmolytic streptococci, as described in the regulations made under the Therapeutic Substances Act, 1925. A 1 in 1000 dilution in physiological solution of sodium chloride produces the characteristic lesions of vaccinia virus when applied to a scarified area of the shaved skin of a rabbit or guinea-pig.

Action and Uses.—Cutaneous inoculation with vaccine lymph results in the production at the site of inoculation of the characteristic eruption of vaccinia. Protective substances are formed by the body as a result of this infection against both vaccinia and variola, and this immunity persists for a considerable number of years. Primary vaccination should be performed in infancy between the ages of two months and six months, and re-vaccination between the ages of six and seven years and again at fourteen to sixteen years. It is advised that only one scarification should be made, with a minimum of trauma.

Post-vaccinal encephalitis, an acute nervous disease with a high mortality rate, occasionally occurs after vaccination. It is associated with characteristic changes in the brain and cord, similar to those found in the acute nervous conditions occasionally following influenza, measles and variola, and has occurred mainly in children of school age, or adolescents who had not previously been vaccinated; it is extremely rare after re-vaccination and after primary vaccination in early infancy. It appears to be established that it is the vaccinia virus which initiates the nervous disturbance, but it is not known why this disturbance should be almost limited to a few individuals only of a particular age group. For the treatment of post-vaccinal encephalitis the serum of a recently successfully vaccinated subject should be given intrathecally in doses of 20 to 30 millilitres daily.

Dose.—0.06 millilitre (1 minim), by scarification.

VALERIANA

(Valerian.)

Valerian*Synonyms*—Valerianæ Rhizoma; Valerian Rhizome; Valerian Root.

Valerian consists of the rhizome and roots of *Valeriana officinalis* Linn. (Fam. Valerianaceæ) collected in the autumn and slowly dried, during which process the characteristic odour develops. In England the drug is obtained from both wild and cultivated plants, of which there are two varieties, var. *Mikanii* Syme being distinguished from var. *sambucifolia* Mikan by the larger average number of leaflets per leaf and by the small number or absence of serrations on the anterior margins of the majority of the leaflets as compared with the posterior margins. *V. officinalis* var. *Mikanii* is found naturally on dry, calcareous heaths and pastures, and constitutes the much esteemed Derbyshire valerian. The drug is also imported largely from Holland and Belgium.

The rhizome is erect about 2 to 5 centimetres long and 1 to 2 centimetres thick, obconical to cylindrical in shape, dull yellowish-brown to dark brown in colour externally and whitish internally. It is entire or irregularly divided obliquely or longitudinally. The fracture is short and horny, showing internally a pale brown, thin cortex, a darker cambium line, a ring of inconspicuous vascular bundles and a large pith. Short stolons may be present, their internodes being about 3 centimetres long, about 2 to 2.5 millimetres in diameter, and longitudinally striated. The numerous roots are about 2 millimetres thick and 2 to 10 or more centimetres long, greyish-brown or brownish-yellow, cylindrical, finely striated longitudinally, brittle, with a broad cortex and a narrow stele. The drug possesses a strong characteristic odour, and the taste is aromatic, somewhat pungent and more or less bitter.

The diagnostic **microscopical** characters are, in the rhizome, the groups of large sclerenchymatous cells, with thick pitted walls, scattered in the large parenchymatous pith; an irregular ring of vascular bundles connected with a cambium and possessing varying amounts of secondary tissues according to age; an endodermis broken by the passing out of the adventitious roots and containing volatile oil; a cortex of parenchyma with slightly thickened, cellulose walls and packed with 2- to 4- compound starch grains, each component with a central hilum, and up to about 20 microns in diameter; a slight periderm: in the root, a more or less collapsed piliferous layer, somewhat papillose in appearance; an exodermis of irregular cells with thin suberised walls and containing volatile oil; cortical parenchyma as in the rhizome; a tetrarch or pentarch primary xylem; a slight pith. The stolons are similar to the rhizome, but show a well-defined ring of vascular bundles in which secondary thickening has taken place, and a prominent endodermis.

Valerian **contains** about 1 per cent. of volatile oil, consisting of bornyl isovalerate, formate, butyrate and acetate, associated with

l-pinene, *l*-camphene and *l*-limonene. Free *isovaleric* acid is gradually liberated during the drying of the drug. It yields to alcohol (60 per cent.) about 20 to 28 per cent. of extractive.

Standard, B.P.—Valerian contains not more than 5 per cent. of foreign organic matter. Ash, not more than 10 per cent.

Valerian, in powder (*Pulvis Valerianæ* : *Pulv. Valerian.*), contains the constituents and possesses the diagnostic microscopical characters of *Valeriana*, and complies with the limit for ash of the unground drug.

Action and Uses.—Valerian is a depressant, its action being attributed alternatively to the valerianic esters of the volatile oil and to its unpleasant odour and taste. It is used as an antispasmodic in hysteria and similar nervous manifestations, and as a carminative. It is **administered** as extract, infusion, or tincture, often in association with the alkali bromides.

Dose.—0.3 to 1 gramme (5 to 15 grains).

Preparations

Elixir Valerianæ, B.P.C.—(*Elix. Valerian.*)—Elixir of Valerian. Simple tincture of valerian, about 1 in 3, with liquid extract of liquorice and aromatic elixir. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Elixir Valerianæ Compositum, B.P.C.—(*Elix. Valerian. Co.*)—Compound Elixir of Valerian. *Syn.*—*Elixir Bromidi et Valerianæ Compositum*; Compound Elixir of Bromide and Valerian. 1 fluid ounce contains $7\frac{1}{2}$ grains each of potassium bromide and chloral hydrate, and 15 minims of liquid extract of valerian, with oils of orange, lemon, coriander and anise, alcohol (95 per cent.), syrup and distilled water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Extractum Valerianæ, B.P.C.—(*Ext. Valerian.*)—Extract of Valerian. A firm extract. Dose.—0.06 to 0.3 gramme (1 to 5 grains).

Extractum Valerianæ Liquidum, B.P.C.—(*Ext. Valerian. Liq.*)—Liquid Extract of Valerian. 1 in 1, prepared from freshly dried valerian. Dose.—0.3 to 1 millilitre (5 to 15 minims).

Infusum Valerianæ Concentratum, B.P.C.—(*Inf. Valerian. Conc.*)—Concentrated Infusion of Valerian. 1 in 5. This concentrated infusion when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength, but not in flavour, to fresh infusion of valerian, and differs also in containing a small proportion of alcohol. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Infusum Valerianæ Recens, B.P.C.—(*Inf. Valerian. Rec.*)—Fresh Infusion of Valerian. 1 in 40. When infusion of valerian or *Infusum Valerianæ* is prescribed, fresh infusion not being specified, either *Infusum Valerianæ Recens* or *Infusum Valerianæ Concentratum* suitably diluted may be dispensed. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Mistura Valerianæ Composita, B.P.C.—(*Mist. Valerian. Co.*)—Compound Valerian Mixture. Each fluid ounce contains 10 grains of potassium bromide and 10 minims of ammoniated tincture of valerian in camphor water. Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

Tinctura Valerianæ Ammoniata, B.P.—(*Tinct. Valerian. Ammon.*)—Ammoniated Tincture of Valerian. 1 in 5, by maceration in a mixture of oils of nutmeg and lemon, dilute solution of ammonia and alcohol (60 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Tinctura Valerianæ Simplex, B.P.C.—(*Tinct. Valerian. Simp.*)—Simple Tincture of Valerian. *Syn.*—*Tinctura Valerianæ*. 1 in 8. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

VALERIANA INDICA

(Valerian. Ind.)

Indian Valerian

Synonyms—Valerianæ Indicæ Rhizoma; Indian Valerian Rhizome.

Indian valerian consists of the dried rhizome and roots of *Valeriana Wallichii* DC. (Fam. Valerianaceæ), a plant indigenous to the Himalayas.

The rhizome, which is dull yellowish-brown in colour, occurs in curved, cylindrical and slightly flattened pieces, about 5 centimetres in length and 10 millimetres in thickness. The upper surface bears numerous, raised, encircling leaf-scars, and the lower surface has prominent, circular root-scars and an occasional thick root. The fracture is short and horny. The smoothed, transverse surface shows a dark cortex and pith, a well-marked cambium line, and a ring of about a dozen small, pale wood bundles separated by wide medullary rays. The odour is valerianaceous but less aromatic than that of valerian, and the taste is bitter.

The diagnostic **microscopical** characters are the tabular cork cells; the resin cells of the cortex; the simple starch grains, about 15 to 20 microns wide, found in the cortex, rays and pith.

Indian valerian **contains** volatile oil, which consists chiefly of sesquiterpenes and contains also valeric acid, both free and in combination as esters. Arachidic acid, hentriacontane, and a mixture of fatty acids have been obtained from the non-volatile constituents of the drug.

Action and Uses.—Indian valerian closely resembles valerian in its properties and is used in India and the Eastern Colonies as a carminative and antispasmodic. An ammoniated tincture of Indian valerian (*Tinctura Valerianæ Indicæ Ammoniatæ*) may be prepared in the same way as ammoniated tincture of valerian.

VANILLA

(Vanill.)

Vanilla

Synonyms—Vanilla Pods; Vanilla Beans.

Vanilla consists of the cured, fully grown fruits of *Vanilla planifolia* Andr. (Fam. Orchidaceæ), a climbing plant indigenous to Mexico, but cultivated in Madagascar, Mexico, the Comoros, Réunion, Tahiti, the Seychelles and other places.

The fruit is a slender capsule, 10 to 25 centimetres long and 8 to 10 millimetres in diameter, flattened-cylindrical in shape, tapering towards each end, wrinkled and flexible, the best varieties being covered with minute, glistening crystals of vanillin. The interior of the fruit contains innumerable, minute, black seeds, embedded in a dark, aromatic, balsamic fluid, secreted by papillæ lining the cavity of the fruit.

Vanilla contains from 2 to 3 per cent. of vanillin; other constituents are vanillic acid, resin (about 4 per cent.), wax and fat (about 10 per cent.), and reducing sugars (about 10 per cent.). The odour and flavour of vanilla is not due entirely to the vanillin, but depends upon the presence of other aromatic substances as yet unidentified. The drug yields to alcohol (70 per cent.) from about 25 to 35 per cent. of extractive.

Varieties.—Vanilla varies very considerably in quality; Réunion (Bourbon), Mexico and Madagascar produce the finest kinds. The fruits from Tahiti contain a lower percentage of vanillin and have an odour slightly different from the other varieties.

Substitutes.—Vanillons, or West Indian vanilla, are the fruits of *Vanilla Pompona* Schiede; they are shorter and much broader than vanilla; they also differ in odour and flavour. Split vanilla beans are of inferior quality; they are generally the result of allowing the fruits to become too ripe before collection.

Uses.—Vanilla is used as a flavouring agent and in perfumery.

VANILLINUM

(Vanillin.)

Vanillin

Synonym—Vanillic Aldehyde.

Vanillin, 4-hydroxy-3-methoxybenzaldehyde, $\text{CH}_3\text{O} \cdot \text{C}_6\text{H}_3(\text{OH}) \cdot \text{CHO}$, is the odorous principle of vanilla and also occurs in Siam benzoin and balsams of Peru and tolu. It is produced synthetically from eugenol and from guaiacol. It occurs in the form of white, crystalline needles or colourless prisms, having the intense odour and taste of vanilla and an acid reaction. The natural substance has the finer flavour. It is completely extracted from its solution in ether by shaking with saturated aqueous solution of sodium bisulphite, from which vanillin may be reprecipitated by sulphuric acid. The aqueous solution gives with lead acetate a white precipitate of a lead compound soluble in hot water, from which it separates in scales on cooling.

The aqueous solution is coloured blue by ferric chloride, becoming brown on boiling; from the liquid, on cooling, a white precipitate of dihydrodivanillin separates. By the action of nascent hydrogen, vanillin is converted into vanillic alcohol, $\text{C}_8\text{H}_{10}\text{O}_3$; on oxidation, it yields odourless vanillic acid, $\text{C}_8\text{H}_8\text{O}_4$. The acid is also produced when vanillin is exposed to moist air. On fusing vanillin with potassium hydroxide, protocatechuic acid, $\text{C}_6\text{H}_3(\text{OH})_2\text{COOH}$, results. When vanillin with twice its weight of pyrogallol is dissolved in alcohol, and hydrochloric acid added to the solution, a blue-violet colouration appears on evaporating the liquid in a porcelain dish; similarly, when phloroglucinol replaces the pyrogallol a fiery red colouration is produced on evaporation. The latter is the well-known Guenzburg's test for free hydrochloric acid in the stomach contents; the reaction is sensitive to 0.05 per cent. of free hydrochloric acid. Being liable

to deterioration from oxidation, vanillin should be **stored** in well-closed bottles in a cool place and protected from light.

Slightly **soluble** in water; more soluble in boiling water; readily soluble in alcohol, ether, chloroform, carbon disulphide, fatty and volatile oils and glycerin; soluble in aqueous solution of alkali hydroxides, forming compounds from which the vanillin is reprecipitated by acids.

Standard.—Vanillin melts between 80° and 82°. Ash, not more than 0·05 per cent. 0·1 gramme, warmed with alcoholic solution of sodium hydroxide and a drop of chloroform, produces no odour of phenyl isocyanide (absence of acetanilide).

Uses.—Vanillin is used as a flavouring agent and in perfumery.

VENTRICULUS DESICCATUS

(Ventricul. Desic.)

Desiccated Stomach

Desiccated stomach is prepared from the fresh whole stomach of the healthy pig, *Sus scrofa* Linn. The stomach is freed from extraneous fat, ground, and dried *in vacuo* at a temperature not exceeding 45°. The dry material is then defatted, dried without further application of heat and milled to a coarse powder. It occurs as a coarse, granular powder having a faint odour and a slight taste. It is sometimes known as stomach extract. Desiccated stomach contains a substance which is capable of causing an increase in the number of red blood cells when administered to patients suffering from pernicious anæmia. No method is known for the assay of desiccated stomach; the only satisfactory criterion of activity is actual clinical test on patients suffering from pernicious anæmia.

Almost **insoluble** in water.

Action and Uses.—Desiccated stomach is used in place of liver extract in the treatment of macrocytic hyperchromic anæmias, that is, pernicious anæmia, the hæmolytic anæmias of pregnancy and sprue, anæmia due to intestinal parasites, anæmia associated with cancer of the stomach and in the anæmia following the surgical removal of a portion of the stomach. It is thought that the substance which exerts a curative effect in these conditions is formed by the action of an intrinsic factor present in normal gastric juice upon an extrinsic factor present in the food digested. The product of the interaction is thermolabile, and after absorption it is converted in the liver into an antianæmic factor which is thermostable. Thus, theoretically, pernicious anæmia may result from a deficiency of either the extrinsic factor or of the intrinsic factor, or from an inability to absorb the product of interaction. In the preparation of desiccated stomach, the intrinsic factor is supplied by the mucous layer, and the extrinsic factor by the muscular tissue of the stomach.

Cases of pernicious anæmia respond to treatment with desiccated stomach in the same way as they do to liver extract. It is useful in cases which are unable to tolerate or do not respond to liver extract, and in some cases appears to exert a curative influence on the nervous symptoms of the disease. Since the response of different patients varies considerably, it is not possible to define the dose within rigid limits, and treatment must be controlled by frequent red blood cell counts. Usually 1 ounce (30 grammes) daily of an active preparation is sufficient as an initial dose, and this should be decreased as the red cell count increases. Response to treatment is shown by an increase in the reticulocytes in the circulating blood, reaching a peak in from seven to twelve days, and thereafter the red blood cells increase rapidly in numbers and the condition of the patient shows marked improvement. As the curative substance is destroyed by heat, desiccated stomach must not be taken in hot liquids (not above 45°). It may be taken in water, milk, wine, cold soup, or mixed with cold foods. Preparations of the mucous layer of the hog's stomach are similarly employed. These contain the intrinsic factor which reacts with protein in the food to produce the substance necessary for the cure of pernicious anæmia.

Dose.— 8 to 30 grammes ($\frac{1}{4}$ to 1 ounce).

VERATRINA

(Veratrin.)

Veratrine

Synonym—Amorphous Veratrine.

Veratrine is a mixture of alkaloids, of variable composition, obtained from *sabadilla* by exhausting the powdered seeds with alcohol. It occurs in the form of white or greyish-white, pulverent masses which are amorphous, odourless and have a very persistent bitter and intensely acrid taste, followed by a sensation of numbness. The powder is a powerful sternutatory. It is slightly hygroscopic in moist air. The alcoholic solution is alkaline to litmus. Its melting-point is indefinite and lies between 145° and 155°. When heated on a water-bath with strong hydrochloric acid, it dissolves with the formation of a blood-red colour which is permanent for several days. When mixed with about five times its weight of powdered sucrose and moistened with concentrated sulphuric acid, an intense green colour is produced, which slowly changes to blue.

Veratrine contains cevadine (crystallised veratrine), $C_{32}H_{49}O_8N$, veratridine, $C_{37}H_{53}O_{11}N$, cevadilline (*sabadilline*), $C_{34}H_{53}O_8N$, *sabadine*, $C_{29}H_{51}O_8N$, and *cevine* (*sabadinine*), $C_{27}H_{43}O_8N$. Cevadine, on hydrolysis, yields *cevine* and a mixture of tiglic and angelic acids, whilst veratridine is hydrolysed to veratric acid and a base which may be identical with *cevine*.

Almost **insoluble** in water; soluble in boiling water (1 in 1000),

alcohol (1 in 3), ether (1 in 6), chloroform (1 in 3) and olive oil (about 1 in 80); sparingly soluble in glycerin; freely soluble in diluted acids, but leaving slight traces of an insoluble, brown, resinous body; very soluble in benzene and amyl alcohol; insoluble in light petroleum.

Standard.—Veratrine leaves not more than 0.3 per cent. of ash. The 5 per cent. w/v solution in water acidified with hydrochloric acid remains clear on the addition of platinic chloride solution (limit of various foreign alkaloids).

Action and Uses.—Veratrine resembles aconitine in its action on the peripheral nerve endings; applied externally, it gives rise to tingling, followed by numbness and coldness, which may be followed by some irritation. Veratrine exerts a characteristic, stimulating direct action on all forms of muscle tissue, which is shown in the case of plain muscle by colic-like spasms of the intestine, exaggeration of the movements of the uterus, bladder, bronchioles, etc., and intense vasoconstriction. The vasoconstriction differs from that caused by adrenaline in that it affects also the pulmonary, coronary and cerebral vessels. The heart is first slowed to a slight extent and then quickened, the strength of systole being increased. Veratrine increases the irritability of striped muscle so as to increase the work it is capable of doing. In large doses the muscle contraction is prolonged, relaxation being long drawn out.

Veratrine is not used internally. It is applied in the form of ointment, or as *Oleinatum Veratrinæ*, for its analgesic properties in neuralgia, especially facial neuralgia, but must not be used where the skin is broken. It is extremely irritating to mucous membrane and should be handled with caution. In cases of **poisoning** by veratrine, the stomach tube should be used or an emetic administered. Stimulants and strong coffee should be given and the recumbent position maintained.

Preparations

Collodium Anodynum, B.P.C.—(Collod. Anodyn.)—Anodyne Collodion. *Syn.*—Anodyne Colloid. Aconitine, about 0.1 per cent., and veratrine, about 0.7 per cent., in acetone and acetone collodion.

Oleinatum Veratrinæ, B.P.C.—(Oleinat. Veratrin.)—Oleinate of Veratrine. Veratrine, 2 per cent. w/w, dissolved in oleic acid and olive oil.

Unguentum Veratrinæ, B.P.C.—(Ung. Veratrin.)—Veratrine Ointment. Veratrine, 2 per cent., in oleic acid and benzoinated lard.

VERATRUM ALBUM

(Verat. Alb.)

White Hellebore

Synonyms—Veratri Albi Rhizoma; White Hellebore Rhizome; Hellebore.

White hellebore consists of the dried rhizome and roots of *Veratrum*

album Linn. (Fam. Liliaceæ), a perennial, herbaceous plant common in the mountains of Central and Southern Europe, being especially abundant in the Alps and Pyrenees. It is usually collected in the late summer, freed from leaves, and sometimes deprived of its roots.

The rhizome is usually simple, about 5 centimetres in length and 20 millimetres in thickness, and crowned with the shrivelled remains of numerous leaf-bases. The upper part is nearly cylindrical, but the lower extremity is bluntly obconical or truncate. It is dull black in colour, the surface being rough and wrinkled, and showing numerous, minute, glistening crystals. Root-scars showing a slender, central xylem are numerous on the trimmed rhizome. The fracture is short; the fractured surface is compact and whitish, showing a narrow cortex separated from the stele by a dark, wavy endodermis. Brown, irregularly arranged bundles are numerous in the stele. The roots are stout and numerous, completely enveloping the rhizome; they are grey in colour and usually longitudinally shrivelled. The drug has an acrid taste, but little odour; the powder is strongly sternutatory.

The diagnostic **microscopical** characters are the dark brown, polygonal cork cells; the cortical parenchyma, containing simple and compound starch grains measuring 4 to 14 microns and bundles of acicular crystals of calcium oxalate; the yellowish cells of the endodermis, thickened on the inner and lateral walls, and the pitted vessels of the xylem. The root shows an outer layer of axially elongated, thickened, brown cells, and pitted, elongated cells of the endodermis.

White hellebore **contains** the crystalline alkaloids, jervine, rubijervine, pseudojervine, protoveratrine and protoveratridine, and an amorphous alkaloid, veratralbine or veratroidine, which may be a decomposition product of protoveratrine. Jervine is the most abundant alkaloid, but the physiological action is mainly due to protoveratrine, which is exceedingly poisonous, and is a powerful sternutatory. The amount of alkaloid varies from 0.5 to 1 per cent.

Action and Uses.—White hellebore was formerly used internally in dropsy and other disorders, and externally as a parasiticide in scabies, etc. It is now rarely employed in medicine.

VERATRUM VIRIDE

(Verat. Vir.)

Green Hellebore

Synonyms—Veratri Viridis Rhizoma; Green Hellebore Rhizome; American Hellebore; American Veratrum.

Green hellebore consists of the dried rhizome and roots of *Veratrum viride* Ait. (Fam. Liliaceæ), a perennial herb which is indigenous to Canada and the North-Eastern United States of America. It is collected in the autumn, generally halved or quartered to facilitate drying, and sometimes deprived of its roots.

The rhizome is about 5 to 8 centimetres long and 2 to 3·5 centimetres wide, sub-cylindrical and obconical below, and crowned with the remains of concentrically arranged leaf-bases which are cut off level with the top of the rhizome. It is grey and rough, and enveloped externally with very numerous, stout, yellowish-brown, transversely shrivelled roots. It has a bitter, acrid taste and the powder is strongly sternutatory.

The diagnostic **microscopical** characters are the bundles of acicular raphides about 60 microns long and 40 microns wide, individual raphides reaching a length of 70 microns, and the starch granules, which are simple or 2- to 4- compound, individual granules being 8 to 10, or up to 21, microns in length.

Green hellebore **contains** the same alkaloids as white hellebore and, in addition, is said to contain cevadine.

Standard.—Green hellebore contains not more than 5 per cent. of foreign organic matter.

Green hellebore, in powder (*Pulvis Veratri Viridis* : *Pulv. Verat. Vir.*), contains the constituents and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—The therapeutic value of green hellebore is due to its powerful effect as a cardiac, arterial and nerve sedative. In puerperal eclampsia it lowers the pulse rate and checks the convulsions. It has been administered in hyperpiesia for the rapid reduction of the blood pressure, the effect being more permanent than that of the nitrites. In aneurism, when the cardiac contractions are strong, it affords relief from pain, especially if given in conjunction with potassium iodide. Green hellebore may be **administered** in the form of the tincture.

Preparation

Tinctura Veratri, B.P.C.—(*Tinct. Verat.*)—Tincture of Green Hellebore. *Syn.*—Tincture of Veratrum. 1 in 10. Dose.—0·3 to 2 millilitres (5 to 30 minims).

VIBURNUM

(*Viburn.*)

Black Haw

Synonyms—*Viburni Cortex*; Black Haw Bark.

Black haw consists of the dried bark of the root of *Viburnum prunifolium* Linn. (Fam. Caprifoliaceæ), a shrub or small tree abundant in the Central and Eastern United States of America.

The bark occurs in channelled or sometimes quilled pieces, 1 to 3 centimetres broad and seldom exceeding 4 millimetres in thickness. The outer surface of the young bark is brownish and smooth, and bears whitish, rounded lenticels; that of the old bark is brownish-grey,

deeply fissured and scaly. The inner surface is yellowish to reddish-brown, and striated or marked with elongated reticulations. Minute glistening points are visible on the outer surface. The fracture is short and granular, and the smoothed, transverse section exhibits a narrow, brown cork and a whitish cortex and phloem, in which are embedded conspicuous, scattered, comparatively large, yellowish groups of sclerenchyma. 0.5 gramme of the bark in powder, added to 5 millilitres of dilute sulphuric acid and warmed, evolves a distinct odour of valeric acid. The odour of the drug is slight, resembling that of valeric acid, and the taste is bitter and astringent.

The diagnostic **microscopical** characters are the numerous stone cells in ovoid masses; the abundant cluster-crystals of calcium oxalate scattered throughout the cortex and phloem; numerous patches of lignified cork cells; the absence of phloem fibres; the starch grains up to 15 microns in diameter.

Black haw **contains** a bitter principle, viburnin, together with fat, resin, tannin, valeric acid and traces of an amorphous, non-volatile alkaloid. The ash is about 4 to 8 per cent. It yields to alcohol (70 per cent.) about 14 per cent. of extractive.

Action and Uses.—Black haw depresses the medulla and spinal cord without affecting the higher cerebral centres; it therefore depresses respiration and induces a large fall in blood pressure, but these effects are obtained only with such large doses that they are without practical significance. It is **administered** as extract and liquid extract, and is used for its supposed sedative effect on the uterus, to prevent threatened abortion and to control hæmorrhage. Good results are said to have followed its administration in asthma, dysmenorrhœa and spasmodic affections of plain muscle, but reliable clinical evidence of its value is lacking.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

Preparations

Elixir Viburni, B.P.C.—(Elix. Viburn.)—Elixir of Black Haw. *Syn.*—Elixir Viburni Prunifolii. Liquid extract of black haw, 1 in 8, with compound tincture of cardamom and aromatic elixir. Dose.—2 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

Elixir Viburni et Hydrastis, B.P.C.—(Elix. Viburn. et Hydrast.)—Elixir of Black Haw and Hydrastis. *Syn.*—Elixir Viburni Compositum; Compound Elixir of Viburnum Prunifolium. Liquid extract of black haw, 1 in 2, and extract of hydrastis, about 1 in 6, with oils of coriander and caraway, and glycerin. Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Extractum Viburni, B.P.C.—(Ext. Viburn.)—Extract of Black Haw. A soft extract. Dose.—0.2 to 0.5 gramme (3 to 8 grains).

Extractum Viburni Liquidum, B.P.C.—(Ext. Viburn. Liq.)—Liquid Extract of Black Haw. 1 in 1. Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

This liquid extract was included in the British Pharmacopœia, 1914.

Liquor Caulophylli et Pulsatillæ Compositus, B.P.C.—(Liq. Cauloph. et Pulsat. Co.)—Compound Solution of Caulophyllum and Pulsatilla. Liquid extracts of caulophyllum, about 1 in 6, pulsatilla, 1 in 20, aletris, 1 in 10, and black haw, 1 in 5, with glycerin and alcohol (60 per cent.). Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

VINUM AURANTII

(Vin. Aurant.)

Orange Wine

Orange wine may be prepared by the fermentation of a saccharine solution containing fresh bitter-orange peel. It is a golden, sherry-coloured liquid with a taste and aroma resembling those of bitter-orange peel.

Standard.—Orange wine, determined by method II of the British Pharmacopœia for the determination of alcohol, contains not less than 12 per cent. and not more than 16 per cent. v/v of ethyl alcohol. It complies also with the Public Health (Preservatives in Food) Regulations, when it contains not more than 450 parts per million of sulphur dioxide, and no other preservative.

Uses.—Orange wine is used as a vehicle for cod-liver oil, quinine salts, etc., and is employed in the preparation of certain medicinal wines.

VINUM XERICUM

(Vin. Xeric.)

Sherry-type Wine

Sherry-type wine is prepared by the fermentation of the juice of fresh grapes, the fruit of *Vitis vinifera* Linn. (Fam. Vitaceæ), freed from seeds, stems and skins. It may be either true sherry, which is prepared only in Spain, or wine of a similar type prepared in other countries, e.g. South Africa or Australia. It is a yellowish-brown liquid with a pleasant aroma and flavour.

Standard.—Sherry-type wine, determined by method I of the British Pharmacopœia for the determination of alcohol, contains not less than 16 per cent. v/v of ethyl alcohol. Specific gravity, 0.990 to 1.000. It contains not less than 0.4 per cent. w/v of total acids, calculated as tartaric acid, $C_4H_6O_6$. It complies also with the Public Health (Preservatives in Food) Regulations, when it contains not more than 450 parts per million of sulphur dioxide, and no other preservative.

Assay.—Titrate 25 millilitres with N/5 sodium hydroxide, using phenolphthalein as indicator; each millilitre of N/5 sodium hydroxide is equivalent to 0.01500 gramme of total acids, calculated as tartaric acid, $C_4H_6O_6$.

Uses.—Sherry was used formerly for preparing several medicated wines; sherry-type wine is now often used for the same purpose.

Preparation

Vinum Xericum Detannatum, B.P.C.—(Vin. Xeric. Detann.)—Detannated Sherry-type Wine. Sherry-type wine detannated with gelatin.

VIOLA CRYSTALLINA

(Viola Crya.)

Crystal Violet*Synonym*—Methyl-rosaniline.

Crystal violet (Colour Index No. 681) is the hydrochloride of hexamethylpararosanine, and may be prepared by the action of dimethylaniline on tetramethyldiaminobenzophenone chloride. It occurs in greenish-bronze crystals or powder. It is precipitated from aqueous solution by tannic acid, and is decolourised by the action of hydrochloric acid and zinc dust, a blue colour being produced on the further addition of a slight excess of ammonia. On the gradual addition of hydrochloric acid to a 0.2 per cent. aqueous solution, the colour changes through bluish-green and green to brownish-yellow, and on further dilution of the solutions the colours are restored in reverse order. The colour base is precipitated by alkalis.

Soluble in water (1 in 20), glycerin (1 in 16) and alcohol (1 in 20); the solution has a violet colour and is decomposed by exposure to light; insoluble in ether.

Standard.—Crystal violet leaves not more than 5 per cent. of sulphated ash. Arsenic limit, 10 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid and add 1 millilitre of potassium ferrocyanide solution; no precipitate is formed (limit of zinc).

Action and Uses.—Crystal violet is a powerful antiseptic, and is considered to possess a selective action on gram-positive organisms. For local use in gynæcological practice a solution is used containing crystal violet and brilliant green; Liquor Tinctorium is a suitable preparation. Crystal violet has been administered intravenously, in doses of 0.005 gramme ($\frac{1}{20}$ grain) per kilogram of body weight, in the treatment of staphylococcal septicæmia. Solutions must be freshly prepared and should contain not more than 1 part of the dye in 200 of distilled water. For both local and intravenous use, crystal violet is preferable to methyl violet and to the commercial gentian violet which may contain a large proportion of dextrin. Solutions of crystal violet may be sterilised by heating at 100° for thirty minutes.

Preparation

Liquor Tinctorium, B.P.C.—(Liq. Tinctor.)—Solution of Brilliant Green and Crystal Violet. Brilliant green and crystal violet, of each 0.5 per cent. w/v, in a mixture of equal parts of alcohol (90 per cent.) and distilled water.

VIRIDE MALACHITUM

(Virid. Malachit.)

Malachite Green

Malachite green (Colour Index No. 657) is the oxalate of *pp'*-tetramethyldiaminotriphenylcarbinol anhydride, $2C_{23}H_{25}N_2 \cdot 3H_2C_2O_4$.

and may be prepared by the condensation of benzaldehyde with dimethylaniline in the presence of sulphuric acid, oxidation of the product with lead peroxide in acid solution, and separation as oxalate by the addition of ammonia and oxalic acid. It occurs as green plates with a metallic sheen. The aqueous solution becomes reddish-yellow on the addition of hydrochloric acid, and a greenish-white precipitate of the colour base separates on the addition of an alkali. The colour base can be crystallised from benzene and melts at about 132° . The leuco-base is formed on reduction, and is reconverted into the colour base on oxidation.

Soluble in water and alcohol.

Standard.—Malachite green leaves not more than 1 per cent. of sulphated ash. Arsenic limit, 10 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid, and add 1 millilitre of potassium ferrocyanide solution; no precipitate is formed (limit of zinc).

Action and Uses.—Malachite green is employed as an antiseptic and disinfectant for dressing wounds, especially in the form of a spray, but is now largely replaced by brilliant green. It should not be applied to mucous membranes and, if alcohol is used as a solvent, the spirit should be allowed to evaporate before applying the dressing. Its action varies greatly with different organisms; it is more strongly inhibitory to gram-positive than to gram-negative organisms. A solution of 1 in 2000 is stated to kill *Staphylococcus aureus* in serum, and a solution of 1 in 5000 to destroy the spores of *Bacillus subtilis*. A solution of 1 in 40,000 is said to kill anthrax bacilli in two hours, but to kill typhoid bacilli in the same time a solution of 1 in 300 is said to be required. It is sometimes used with mercuric chloride in the form of a recently prepared mixture of equal parts of 2 per cent. solutions in alcohol (80 per cent.).

VIRIDE NITENS

(Virid. Nit.)

Brilliant Green

Brilliant green (Colour Index No. 662), $C_{27}H_{33}N_2 \cdot SO_4H$, is the sulphate of tetraethyldiaminotriphenylcarbinol anhydride, and may be prepared by oxidising the product of condensation between diethylaniline and benzaldehyde and converting it into the sulphate. It occurs in small, glistening, golden crystals. The aqueous solution becomes reddish-yellow on the addition of hydrochloric acid, and a pale green precipitate of the colour base is formed on the addition of an alkali. The solution becomes colourless on reduction with zinc and hydrochloric acid, and the colour is not restored immediately on exposure to air.

but is restored by oxidising agents such as chromic acid. Brilliant green (fat-soluble) is the stearate of brilliant green base.

Soluble in water and alcohol.

Standard.—Brilliant green leaves not more than 5 per cent. of sulphated ash. Arsenic limit, 25 parts per million. Lead limit, 100 parts per million. Dissolve the sulphated ash from 1 gramme in 20 millilitres of water and 2 millilitres of dilute hydrochloric acid and add 1 millilitre of potassium ferrocyanide solution; no precipitate is produced (limit of zinc).

Action and Uses.—Brilliant green is an antiseptic and disinfectant, and is especially useful in the treatment of wounds. In solution, 1 in 2000 to 1 in 1000 of distilled water or hypertonic saline, it is non-irritating and powerfully bactericidal in action while being harmless to phagocytes and to the tissues. Exuberant growths of bright red granulation tissue form early. It is, therefore, used in preparing granulating surfaces for grafts. It is to some extent inactivated by blood serum and hence must be frequently renewed in an infected wound. It may be used for the irrigation of wounds by Carrel's method in place of Dakin's solution. A 1 in 1000 solution of brilliant green in an aqueous solution of allantoin (0.25 per cent.) is commonly used to promote epithelialisation after radical mastoid operations, 20 drops being instilled into the cavity after cleansing the wound. Solutions of brilliant green may be prepared by aseptic methods.

An ointment containing 1 to 2 per cent. of brilliant green dissolved in a small quantity of alcohol and incorporated with soft paraffin has been found to be most useful in the treatment of superficial wounds and minor injuries. A paste containing brilliant green, 1 part, boric acid, 275 parts, purified talc, 25 parts, and liquid paraffin, 200 parts, is used for filling wound cavities. Brilliant green mixed with an equal quantity of crystal violet is known as "violet green," and in solution as Liquor Tinctorium it forms a very efficient application for sterilising the skin. In special skin areas such as the perianal region, this solution is preferable to iodine, since it is non-irritating while being actively antiseptic. A 5 per cent. w/v aqueous solution of brilliant green has been used as a local treatment in erysipelas. The solution is painted over the affected areas once or twice daily. It gives relief to the patient and limits the spread of the infection, causing the rash and fever to disappear rapidly.

Brilliant green appears to have a selective action on bacteria. It has been found to kill the gram-positive organisms, *Bacillus subtilis* and *Staphylococcus aureus*, at dilutions of 1 in 15,000,000 and 1 in 4,000,000 respectively, while a concentration of 1 in 600,000 was required to kill the gram-negative *B. coli*, but another closely related gram-negative organism, *B. dysenteriae*, was killed by a dilution of 1 in 1,500,000. It has a specially inhibitory action on the usual types of *B. coli*, and this renders it of particular service in certain bacteriological examinations. For example, there is the brilliant green enrichment method for the isolation of the enteric group in faeces

which depends on the fact that in fluid media containing certain concentrations of brilliant green the typhoid-paratyphoid bacilli grow well, while the growth of *B. coli* is partly or completely inhibited, and the former organisms can be enriched at the expense of the latter.

Preparation

Liquor Tinctorium, B.P.C.—(Liq. Tinctor.)—Solution of Brilliant Green and Crystal Violet. Brilliant green and crystal violet, of each 0.5 per cent., in a mixture of equal parts of alcohol (90 per cent.) and distilled water.

VISCUM

(Visc.)

Mistletoe

Mistletoe consists of the dried, evergreen, diœcious semi-parasite, *Viscum album* Linn. (Fam. Loranthaceæ), which grows on the branches of deciduous trees, chiefly apple, poplar and plum.

The drug occurs as a mixture of broken stems and leaves and occasional fruits. The repeatedly forked stem is largely broken into separate internodes, which are slender, glabrous and yellowish-green, up to about 12 centimetres long and 3 millimetres in diameter, enlarged at the ends, where there is a double scar, and longitudinally wrinkled; the smaller proportion of older stems are brownish-green, and attain a diameter of about 7 millimetres and show both transverse and longitudinal wrinkles. The leaves are opposite, glabrous, coriaceous and yellowish-green; they are about 5 centimetres long, oblanceolate, with entire margins, rounded apices, and 4 or 5 parallel, longitudinal veins. The fruit is about 7 millimetres in diameter, irregularly wrinkled and yellowish-brown. The drug is odourless and has an insipid taste.

Mistletoe **contains** an amorphous, resinous body, viscin, inositol, ursone, a wax alcohol, palmitic acid, choline, invert sugar and a pectin-like carbohydrate. It yields to water about 23 per cent. of extractive.

Substitute.—*Phoradendron flavescens* Nutt. is known as mistletoe in the United States of America. It has similar but shorter leaves of a more yellow colour, and is somewhat pubescent.

Action and Uses.—On account of its vasodilator action, mistletoe has been used for lowering blood pressure. Its action is usually delayed and a maximum effect is reached three to four days after the commencement of treatment. It is also said to lessen the cardiac impulse and to relieve precordial distress, effects which are probably due to the dilatation of the peripheral vessels. It has also been found useful in cases of hysteria and chorea. Mistletoe is **administered** as a soft extract in pills, or as an infusion or tincture (1 in 8).

YOHIMBA

(Yohimb.)

Yohimbe*Synonyms*—Yohimbe Bark; Yohimbæ Cortex.

Yohimbe is the bark obtained from *Pausinystalia yohimba* Pierre ex Beille (Fam. Rubiaceæ), a tree indigenous to the Cameroons and the French Congo.

The bark occurs in flat or channelled pieces, 2 to 10 or sometimes up to 20 millimetres thick, with a varying tinge of red in the grey-brown or brown outer and inner surfaces. The cork is firmly adherent, longitudinally furrowed, and bears numerous, narrow, transverse cracks at fairly regular intervals of 1 to 2 centimetres. The inner surface is reddish-brown and smooth, with very fine longitudinal striations. The bark breaks easily with a soft, almost velvety fracture, which is splintery and shortly fibrous in the inner part. A few grains of the bark scraped from the inner surface, shaken with a mixture of 5 drops of strong solution of ammonia and 10 millilitres of water, gradually develop a colour varying from wine-red to distinct reddish-brown. The drug is odourless, and has a slightly bitter taste.

The diagnostic **microscopical** characters are, in the transverse section, the characteristic beaded appearance, due to the alternation of bast fibres with parenchymatous cells in the outer zone of the bast, the bast fibres being mostly isolated and only occasionally in tangential groups of two or three.

Yohimbe **contains** as the chief constituent the alkaloid, yohimbine (quebrachine). It also contains *isoyohimbine* (*mesoyohimbine*), dihydroyohimbine, *alloyohimbine*, yohimbene, and a number of other alkaloids. The total amount of alkaloid varies from 0.3 to 1.5 per cent.

Substitute.—The bark of *P. macroceras* (K. Sch.) Pierre differs from yohimbe bark chiefly in the arrangement of the bast fibres, which in the outer zone of the bast are usually in tangential groups of two, and in the brown colour, with sometimes a slight tinge of red, which it yields to very dilute ammonia. It contains a pharmacologically inactive alkaloid, yohimbinine.

Use.—Yohimbe is used principally as the source of yohimbine.

YOHIMBINÆ HYDROCHLORIDUM

(Yohimb. Hydrochlor.)

Yohimbine Hydrochloride

Yohimbine hydrochloride is the hydrochloride of the principal alkaloid of yohimbe bark. The alkaloid is probably identical with quebrachine found in white quebracho bark, *Aspidosperma Quebracho* Schlecht. Yohimbine hydrochloride may be obtained by treating the ether-soluble alkaloids of yohimbe bark with alcoholic hydrogen chloride, and triturating the resinous mixture of hydrochlorides, so

precipitated, with acetone. The crude hydrochloride can be purified by crystallisation from hot water or alcohol. It occurs as a white, odourless, crystalline powder having a bitter taste.

A solution of yohimbine hydrochloride in water is neutral or faintly acid to litmus. It melts at about 300°. 0.01 gramme dissolved in 1 millilitre of sulphuric acid develops no colour, but on adding a minute crystal of potassium dichromate, violet streaks appear, the solution becoming slate blue and finally changing to green. A few milligrams of yohimbine hydrochloride added to 2 or 3 drops of fuming nitric acid immediately becomes dark green and finally forms a yellow solution which, on the addition of 2 millilitres of alcoholic potassium hydroxide solution, develops a cherry-red colour. 0.01 gramme moistened with about 3 drops of sulphuric acid and the mixture well stirred with about 0.05 gramme of ammonium vanadate produces a violet colour, but on dilution with water the liquid does not become reddish in colour (distinction from strychnine).

Soluble in cold water (1 in 100); more soluble in hot water and alcohol.

Standard.—Yohimbine hydrochloride loses, on drying at 100°, not more than 2 per cent. of its weight, and the dried material has a specific rotation of about +100° in water. Ash, not more than 0.1 per cent. The addition of a few drops of sodium carbonate solution to 10 millilitres of a 1 per cent. solution of the hydrochloride in water produces a white precipitate of yohimbine which, after being washed with water and dried in a desiccator, has a melting-point of 230° to 235°.

Action and Uses.—Yohimbine is an aphrodisiac, and its action as such is said to be superior to that of strychnine in that, whilst strychnine increases all reflexes, yohimbine increases only the pelvic reflexes. It exerts an anæsthetic action upon sensory nerve terminations. It lowers blood pressure by dilating vessels; this action is exerted upon the walls of the vessels themselves, and affects most vessels, such as those of the skin, kidney, intestines and external genital organs. It increases the depth and frequency of respiration. Poisonous doses paralyse respiration. It is employed hypodermically or by the mouth as a sexual stimulant in impotence. It is usually given in the form of the hydrochloride, and the salt may be **administered** in pills, which should be prepared with lactose and glycerin of tragacanth, and also in tablets. For hypodermic injection, a 1 per cent. solution is usually prepared. Solutions of yohimbine hydrochloride for **injection** may be sterilised by heating at 100° for thirty minutes or by filtration, and the containers should comply with the tests for limit of alkalinity of glass.

Dose.—0.003 to 0.008 gramme ($\frac{1}{20}$ to $\frac{1}{8}$ grain).

YOHIMBINA.—Yohimbine, regenerated from the hydrochloride, crystallises from dilute alcohol in colourless needles. It is readily soluble in alcohol and chloroform, and sparingly soluble in ether. Yohimbine has been described formerly under the name of Corynina.

ZANTHOXYLUM

(Zanthox.)

Zanthoxylum

Synonyms—Prickly Ash Bark; Toothache Bark; Xanthoxylum.

Zanthoxylum consists of the dried bark of *Zanthoxylum americanum* Mill. (northern prickly ash) or *Z. Clava-Herculis* Linn. (southern prickly ash), (Fam. Rutaceæ), two American shrubs, the former growing in the Northern, Middle and Western States and the latter in the South, from Virginia to Texas.

Northern prickly ash bark occurs in curved or quilled, brownish-grey fragments, about 0.5 to 3 millimetres thick, from 2 to 15 centimetres in length, and up to 3.5 centimetres wide. Externally, it is brown to brownish-black, with greyish patches of lichens bearing numerous black apothecia, and bears numerous white lenticels and occasional small emergences ending in spines. The fracture is short. The yellowish-white inner surface exhibits fine longitudinal striations and numerous glistening crystals. Southern prickly ash bark occurs in irregularly oblong, flattened or curved pieces, and occasionally in single quills from 5 to 40 centimetres long, 1 to 10 centimetres wide, and 1 to 4 millimetres thick. The outer surface is frequently marked with prominent, limpet-shaped, conical, corky emergences, often bearing stout spines; the inner surface is obscurely striated longitudinally, and shows many small, glistening crystals. Both barks have a slight odour and a bitter, acrid, pungent taste.

The diagnostic **microscopical** characters are the numerous, nearly spherical starch grains, from 2 to 10 microns in diameter; the stone cells up to 150 microns in length, and frequently containing reddish-brown contents; the irregular fragments of nearly colourless, lignified cork cells; the numerous glands containing droplets of secretion; the crystals of calcium oxalate from 10 to 250 microns in length.

Zanthoxylum **contains** two resins, one acrid, the other crystalline and bitter. Southern prickly ash also contains a bitter, alkaloidal principle resembling berberine, and northern prickly ash contains a crystalline phenol, xanthoxylin. The total ash is about 6 per cent., and the acid-insoluble ash about 0.3 per cent.

Standard.—*Zanthoxylum* contains not more than 2 per cent. of foreign organic matter.

Zanthoxylum, in powder (*Pulvis Zanthoxyli*: *Pulv. Zanthox.*), contains the constituents, and possesses the diagnostic microscopical characters of the unground drug.

Action and Uses.—*Zanthoxylum* acts as a carminative and stimulant to the gastro-intestinal tract, and produces, after absorption, some diuresis and diaphoresis. It has been **administered** in the form of a liquid extract, with belladonna and hyoscyamus, in the treatment of alcoholism.

Dose.—1 to 2 grammes ($\frac{1}{4}$ to $\frac{1}{2}$ drachm).

ZINCI ACETAS

(Zinc. Acet.)

Zinc Acetate

Zinc acetate, $\text{Zn}(\text{CH}_3\text{COO})_2 \cdot 2\text{H}_2\text{O}$, may be prepared by neutralising acetic acid with zinc carbonate or oxide, filtering the solution while hot, and crystallising. It occurs in the form of thin, soft, white, glistening, translucent plates or monoclinic crystals of a pearly lustre, and having a faint, acetous odour and a sharp, disagreeable, metallic taste. On exposure, the salt gradually effloresces, loses acetic acid, and becomes converted into a basic salt. The aqueous solution of the salt loses acetic acid also on boiling and deposits the basic salt. When heated, it partly fuses, losing its water of crystallisation and acetic acid; at a higher temperature it is decomposed, with evolution of acetone, etc., leaving a residue of zinc oxide. By drying over sulphuric acid at ordinary temperature the anhydrous salt may be obtained. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 2.5), boiling water (4 in 1), alcohol (1 in 40) and boiling alcohol (1 in 3).

Standard.—Zinc acetate, determined by the method of the British Pharmacopœia for Zinci Sulphas, contains not less than 99.5 per cent. of $\text{C}_4\text{H}_6\text{O}_4\text{Zn} \cdot 2\text{H}_2\text{O}$; each millilitre of M/5 potassium iodate is equivalent to 0.007315 gramme of $\text{C}_4\text{H}_6\text{O}_4\text{Zn} \cdot 2\text{H}_2\text{O}$. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 0.1 gramme complies with the limit test for iron. The aqueous solution is neutral or only faintly acid to litmus. It complies with the limit test for copper, aluminium, nickel, manganese, and magnesium in Zinci Sulphas.

Action and Uses.—Zinc acetate closely resembles zinc sulphate in its action. It is employed in the form of lotion as an astringent in ophthalmia.

Dose.—0.06 to 0.12 gramme (1 to 2 grains); as an emetic, 0.6 gramme (10 grains).

ZINCI BROMIDUM

(Zinc. Brom.)

Zinc Bromide

Zinc bromide may be prepared by dissolving zinc in hydrobromic acid, filtering the solution through asbestos or glass wool, concentrating, acidifying with a little hydrobromic acid, and evaporating to dryness on a water-bath, or by stirring 36 parts of freshly ignited zinc oxide with 150 parts of water, gradually adding 288 parts of 25 per cent. w/w hydrobromic acid, or sufficient to give a weak but distinctly

acid reaction, and evaporating the solution to dryness on a water-bath. It occurs as a white or nearly white, very deliquescent, odourless, granular powder, having a sharp, saline, styptic, metallic taste. It sometimes contains basic salt, and is then not completely soluble in water. The aqueous solution has a slightly acid reaction to litmus. Zinc bromide melts at about 394° , with partial decomposition, forming a colourless or yellowish liquid boiling at about 700° and, out of contact with air, subliming in needle-shaped crystals.

Soluble in water (4 in 1), alcohol (2 in 1) and ether.

Standard.—Zinc bromide, determined by the method of the British Pharmacopœia for Zinci Sulphas, contains not less than 95 per cent. of ZnBr_2 ; each millilitre of M/5 potassium iodate is equivalent to 0.007507 gramme of ZnBr_2 .

Action and Uses.—Zinc bromide has been used in epilepsy, but the small amount of bromide present in the doses administered for this purpose has little effect. It is best administered in mixture form with dilute hydrobromic acid. It is **incompatible** with borax and with soluble carbonates.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

ZINCI CARBONAS

(Zinc. Carb.)

Zinc Carbonate

Synonyms—Hydrated Zinc Carbonate; Zinc Subcarbonate.

Zinc carbonate is a basic carbonate, and may be prepared by the interaction of zinc sulphate and sodium carbonate. It occurs as a dry, white, odourless, tasteless, impalpable, amorphous powder. When strongly heated it loses water and carbon dioxide, leaving a residue of zinc oxide. It varies slightly in composition, corresponding approximately to the formula $\text{ZnCO}_3, 2\text{ZnO}, 3\text{H}_2\text{O}$.

Insoluble in water and alcohol; soluble in dilute nitric and other mineral acids with effervescence, and in acetic acid, solution of ammonia and solution of ammonium carbonate.

Standard.—Zinc carbonate yields on ignition not less than 68 per cent. of residue. Arsenic limit, 10 parts per million. 0.5 gramme with 3 millilitres of nitric acid complies with the limit test for chlorides. 0.2 gramme with 2 millilitres of hydrochloric acid complies with the limit test for sulphates. 0.1 gramme complies with the limit test for iron. Dissolve 2 grammes in 20 millilitres of water and 5 millilitres of glacial acetic acid; the solution remains clear on the addition of 5 drops of potassium chromate solution (limit of lead).

Action and Uses.—Zinc carbonate is a mild astringent and protective to the skin, and is sometimes used in place of zinc oxide or calamine in dusting powders and lotions.

ZINCI ACETAS

(Zinc. Acet.)

Zinc Acetate

Zinc acetate, $\text{Zn}(\text{CH}_3 \cdot \text{COO})_2 \cdot 2\text{H}_2\text{O}$, may be prepared by neutralising acetic acid with zinc carbonate or oxide, filtering the solution while hot, and crystallising. It occurs in the form of thin, soft, white, glistening, translucent plates or monoclinic crystals of a pearly lustre, and having a faint, acetous odour and a sharp, disagreeable, metallic taste. On exposure, the salt gradually effloresces, loses acetic acid, and becomes converted into a basic salt. The aqueous solution of the salt loses acetic acid also on boiling and deposits the basic salt. When heated, it partly fuses, losing its water of crystallisation and acetic acid; at a higher temperature it is decomposed, with evolution of acetone, etc., leaving a residue of zinc oxide. By drying over sulphuric acid at ordinary temperature the anhydrous salt may be obtained. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 2.5), boiling water (4 in 1), alcohol (1 in 40) and boiling alcohol (1 in 3).

Standard.—Zinc acetate, determined by the method of the British Pharmacopœia for Zinci Sulphas, contains not less than 99.5 per cent. of $\text{C}_4\text{H}_6\text{O}_4\text{Zn} \cdot 2\text{H}_2\text{O}$; each millilitre of M/5 potassium iodate is equivalent to 0.007315 gramme of $\text{C}_4\text{H}_6\text{O}_4\text{Zn} \cdot 2\text{H}_2\text{O}$. 1 gramme complies with the limit test for chlorides. 1 gramme complies with the limit test for sulphates. 0.1 gramme complies with the limit test for iron. The aqueous solution is neutral or only faintly acid to litmus. It complies with the limit test for copper, aluminium, nickel, manganese, and magnesium in Zinci Sulphas.

Action and Uses.—Zinc acetate closely resembles zinc sulphate in its action. It is employed in the form of lotion as an astringent in ophthalmia.

Dose.—0.06 to 0.12 gramme (1 to 2 grains); as an emetic, 0.6 gramme (10 grains).

ZINCI BROMIDUM

(Zinc. Brom.)

Zinc Bromide

Zinc bromide may be prepared by dissolving zinc in hydrobromic acid, filtering the solution through asbestos or glass wool, concentrating, acidifying with a little hydrobromic acid, and evaporating to dryness on a water-bath, or by stirring 36 parts of freshly ignited zinc oxide with 150 parts of water, gradually adding 288 parts of 25 per cent. w/w hydrobromic acid, or sufficient to give a weak but distinctly

acid reaction, and evaporating the solution to dryness on a water-bath. It occurs as a white or nearly white, very deliquescent, odourless, granular powder, having a sharp, saline, styptic, metallic taste. It sometimes contains basic salt, and is then not completely soluble in water. The aqueous solution has a slightly acid reaction to litmus. Zinc bromide melts at about 394° , with partial decomposition, forming a colourless or yellowish liquid boiling at about 700° and, out of contact with air, subliming in needle-shaped crystals.

Soluble in water (4 in 1), alcohol (2 in 1) and ether.

Standard.—Zinc bromide, determined by the method of the British Pharmacopœia for Zinci Sulphas, contains not less than 95 per cent. of ZnBr_2 ; each millilitre of M/5 potassium iodate is equivalent to 0.007507 gramme of ZnBr_2 .

Action and Uses.—Zinc bromide has been used in epilepsy, but the small amount of bromide present in the doses administered for this purpose has little effect. It is best administered in mixture form with dilute hydrobromic acid. It is **incompatible** with borax and with soluble carbonates.

Dose.—0.12 to 0.3 gramme (2 to 5 grains).

ZINCI CARBONAS

(Zinc. Carb.)

Zinc Carbonate

Synonyms—Hydrated Zinc Carbonate; Zinc Subcarbonate.

Zinc carbonate is a basic carbonate, and may be prepared by the interaction of zinc sulphate and sodium carbonate. It occurs as a dry, white, odourless, tasteless, impalpable, amorphous powder. When strongly heated it loses water and carbon dioxide, leaving a residue of zinc oxide. It varies slightly in composition, corresponding approximately to the formula $\text{ZnCO}_3, 2\text{ZnO}, 3\text{H}_2\text{O}$.

Insoluble in water and alcohol; soluble in dilute nitric and other mineral acids with effervescence, and in acetic acid, solution of ammonia and solution of ammonium carbonate.

Standard.—Zinc carbonate yields on ignition not less than 68 per cent. of residue. Arsenic limit, 10 parts per million. 0.5 gramme with 3 millilitres of nitric acid complies with the limit test for chlorides. 0.2 gramme with 2 millilitres of hydrochloric acid complies with the limit test for sulphates. 0.1 gramme complies with the limit test for iron. Dissolve 2 grammes in 20 millilitres of water and 5 millilitres of glacial acetic acid; the solution remains clear on the addition of 5 drops of potassium chromate solution (limit of lead).

Action and Uses.—Zinc carbonate is a mild astringent and protective to the skin, and is sometimes used in place of zinc oxide or calamine in dusting powders and lotions.

ZINCI CHLORIDUM

(Zinc. Chlorid.)

Zinc Chloride

Zinc chloride may be obtained by dissolving zinc in hydrochloric acid, evaporating the resulting solution, fusing the residue and pouring into moulds to solidify. It occurs in the form of opaque, white sticks or masses, or as a white, or nearly white, granular powder; it is very deliquescent and caustic. On heating, it melts to a clear liquid at about 260° , and at a higher temperature it is partly volatilised, forming dense white fumes and leaving a residue of zinc oxide. Heated in a current of chlorine it sublimes unchanged in acicular crystals. Zinc chloride almost always contains some oxychloride and is therefore not completely soluble in water; the aqueous solution is alkaline to methyl orange; if made neutral to methyl orange by the addition of a few drops of dilute hydrochloric acid, a clear solution is obtained. When the aqueous solution is heated, hydrogen chloride is given off and a precipitate of zinc oxychloride forms.

Soluble in water (1 in less than 1), alcohol (90 per cent.) (about 1 in 1.5) and glycerin (1 in 2).

Standard, B.P.—Zinc chloride contains zinc equivalent to not less than 95 per cent. of ZnCl_2 . It complies also with limit tests for oxychloride and for ammonia.

Action and Uses.—Zinc chloride is a powerful caustic and astringent, and is principally employed externally as a lotion (1 in 25 to 1 in 50) for offensive ulcers and for application to wounds. It is sometimes applied in the form of a paste or pencil to lupus and ulcerous sores. It burns deeply and does not spread over the surrounding parts. For ophthalmic use, lotions or drops of 1 grain in 1 fluid ounce are employed, sometimes with the addition of cocaine. A solution of zinc chloride in water, 1 in 200, is said to be a good deodorant. *Liquor Zinci Chloridi* is used as a disinfectant and deodorant, and may be conveniently employed for dispensing zinc chloride in solution; 4 minims of the solution contains approximately 3 grains of zinc chloride.

Solutions of zinc chloride generally become turbid owing to the formation of oxychloride; a slight opalescence in eye drops of zinc chloride may be disregarded; on no account should acid be added to dissolve it. When solutions of zinc chloride are required to be filtered, asbestos or glass wool should be used, since paper and cotton wool are dissolved by them. When zinc oxide is moistened with a strong solution of zinc chloride, an oxychloride is formed which sets into a hard mass; this forms the basis of some dental cements. **Poisoning** by zinc chloride is characterised by corrosion and inflammation of the mucous membrane of the mouth and stomach, which is usually rendered white. Ulceration, often followed by perforation, may also be evident. Treatment consists in the liberal administration of alkali carbonate, milk, or white of egg.

Preparation

Liquor Zinci Chloridi, B.P.C.—(Liq. Zinc. Chlorid.)—Solution of Zinc Chloride. It contains zinc chloride equivalent to about 40 per cent. of metallic zinc.

This solution, prepared by a process which included a method for the removal of lead and iron, if present, was included in the British Pharmacopœia, 1914.

ZINCI IODIDUM

(Zinc. Iod.)

Zinc Iodide

Zinc iodide may be prepared by digesting 3 parts of zinc granules or filings with 10 parts of iodine in 20 parts of water until the liquid has become colourless or nearly so, or by dissolving zinc oxide or carbonate in hydriodic acid. The solution is filtered through asbestos or glass wool, and rapidly evaporated to dryness at a gentle heat. It occurs as a yellowish-white, granular, odourless, crystalline powder, having a sharp, saline, styptic, metallic taste. It is very deliquescent and on exposure to air and light becomes brown due to liberation of iodine. The aqueous solution is acid to litmus. Zinc iodide melts at about 446° forming a colourless liquid, and at a higher temperature it sublimes, forming quadratic needles, but partly decomposing with liberation of iodine and leaving a residue of zinc oxide. This decomposition also occurs at ordinary temperatures on long exposure to light and air.

Freely **soluble** in water, alcohol and ether.

Standard.—Zinc iodide, determined by the method of the British Pharmacopœia for Potassii Iodidum, contains not less than 98 per cent. of ZnI_2 ; each millilitre of M/20 potassium iodate is equivalent to 0.01596 gramme of ZnI_2 . Arsenic limit, 5 parts per million. 1 gramme complies with the limit test for sulphates. 0.1 gramme complies with the limit test for iron.

Action and Uses.—Zinc iodide has been employed in epilepsy and in tertiary syphilis. The iodide is present in too small an amount to exert much effect, however, and the salt is now rarely used. It is best administered in solution, well diluted.

Dose.—0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

CADMII IODIDUM.—Cadmium iodide, CdI_2 , occurs as nearly colourless, odourless, shining, crystalline flakes, having a nauseous, metallic taste. It melts at about 390° to 400° , forming an amber-coloured liquid, and decomposes at a dull red heat with evolution of iodine vapours. It is soluble in water (1 in 1), the solution having an acid reaction, in boiling water (1 in 0.75), and in alcohol. The action of cadmium iodide resembles that of zinc salts, although it is a more powerful emetic. It is now rarely employed except as a reagent.

ZINCI OLEOSTEARAS

(Zinc. Oleostear.)

Zinc Oleostearate

Zinc oleostearate is prepared as follows:—Dissolve 20 parts of hard soap and 10 parts of curd soap in 150 parts of water with the aid of heat; dissolve 10 parts of zinc sulphate in 20 parts of boiling water, and add it to the former solution; stir well, separate the oleostearate, wash with hot water until free from sulphate, then cool, dry and powder the product. Old or partly dried soap should not be used. It occurs as a white, amorphous powder having a faint odour resembling that of fat.

Insoluble in water, alcohol and ether.

Standard.—Zinc oleostearate, determined by the method of the British Pharmacopœia for Zinci Stearas, contains not less than 12 per cent. and not more than 14 per cent. of zinc, calculated as ZnO. It complies with the limit tests for alkalis and alkaline earths, and free fatty acids in Zinci Stearas.

Action and Uses.—Zinc oleostearate is used to protect the surface of the skin in excoriations, to allay irritation, and to absorb discharges in moist eczematous conditions. It may be used as a compound dusting powder, such as Pulvis Zinci Oleostearatis Compositus, or in the form of an ointment.

Preparations

Linimentum Calaminæ Compositum, B.P.C.—(Lin. Calamin. Co.)—Compound Liniment of Calamine. Calamine, 1 in 10, with zinc oxide, zinc oleostearate, wool fat, white soft paraffin and liquid paraffin.

Pulvis Zinci Oleostearatis Compositus, B.P.C.—(Pulv. Zinc. Oleostear. Co.)—Compound Zinc Oleostearate Powder. Zinc oleostearate and boric acid, of each 1 in 4, with starch, perfumed with oil of geranium.

Unguentum Zinci Oleatis, B.P.—(Ung. Zinc. Oleat.)—Ointment of Zinc Oleate. *Syn.*—Zinc Oleate Ointment. Freshly precipitated zinc oleate, 50 per cent., in white soft paraffin.

ZINCI OXIDUM

(Zinc. Oxid.)

Zinc Oxide $\text{ZnO} = 81.38$

Zinc oxide may be obtained by the combustion of metallic zinc in a current of air, or by igniting zinc carbonate. It occurs as a soft, white or faintly yellowish-white, amorphous powder, free from grittiness, and without odour or taste. When strongly heated it becomes yellow, but changes to white again on cooling. It gradually absorbs carbon dioxide and moisture when exposed to the air. By heating with magnesium it is reduced to metallic zinc with explosive violence. It

forms cement-like products when mixed with a strong solution of zinc chloride or with phosphoric acid, owing to the formation of oxy-salts; when required for this purpose, zinc oxide of high density is preferable. It dissolves in dilute mineral acids with formation of salts; and in solutions of alkali hydroxides with formation of zincates. Commercial zinc oxide, manufactured for use as a pigment, is known as "zinc white."

Insoluble in water and alcohol (95 per cent.).

Standard, B.P.—Zinc oxide contains not less than 99 per cent. of ZnO , calculated on the freshly ignited substance. Loss on ignition, not more than 1 per cent. Arsenic limit, 10 parts per million. It complies also with a test for absence of metallic zinc, and with limit tests for lead and iron.

Action and Uses.—The salts of zinc resemble those of copper in so far as they are caustic and astringent, but as antiseptics the copper salts are superior. Zinc salts are given internally for their supposed sedative action on the central nervous system in epilepsy, chorea and hysteria, but their usefulness is doubtful. Their absorption is slow and incomplete. Zinc oxide is less astringent than the soluble salts and has been given in pills to check the night-sweats of phthisis, but its action compared with that of atropine is very feeble.

Zinc oxide has a wide application externally in the form of dusting powders, ointments, pastes and lotions as a mild astringent for the skin, as a soothing and protective application in eczema, and as a protective to slight excoriations. Mixed with boric acid it is useful to check excessive perspiration. Zinc oxide is usually **administered** in pills, often with dry extract of belladonna. The inhalation of zinc oxide during the combustion of the metal results in fever, headache, nausea and cramp, followed by perspiration and rapid recovery—a condition known as brass-founder's ague.

Dose.—0.3 to 0.6 gramme (5 to 10 grains)

STANNI OXIDUM.—Stannic oxide, SnO_2 , may be prepared by burning the metal in air, or by oxidising it with nitric acid and igniting the residue. It occurs as a greyish-white powder and is insoluble in water and hydrochloric acid, but reacts with caustic alkalis forming soluble stannates which yield a precipitate of stannic acid on adding acid to an aqueous solution. The crude product frequently contains an appreciable amount of lead and is commonly known as "putty powder." Tin and its salts appear to possess a specific action against infections due to staphylococci, and tin oxide, often associated with free tin, is administered for the treatment of boils, carbuncles and acne. It has been stated that during the treatment of boils by tin the output of chlorides and urea in the urine is simultaneously increased. As the boils disappear, excretion of chloride and urea again becomes normal. **Dose.**—0.5 to 1 gramme (8 to 15 grains) daily.

TITANI OXIDUM.—Titanic oxide, or titanium dioxide, TiO_2 , is the most stable oxide of titanium, and occurs in an impure form as rutile. It may be prepared by burning the metal in oxygen, or by ignition of the hydroxide produced by the addition of alkalis to solutions of titanic salts, or by boiling solutions of titanates. It occurs as a whitish powder, insoluble in water. It is amphoteric and, when in the hydrated form, will dissolve in acids to produce colourless titanic compounds, and in alkalis, yielding titanates. It is reduced only with the greatest difficulty.

Titanic oxide is used as an ingredient of face powders and other toilet articles of like nature. It is also used in preparing titanium paints, which have a greater covering power than lead paints and are non-poisonous, unaffected by light, and not discoloured by the usual impurities in the air. The trivalent salts of titanium are strong reducing agents.

Preparations

Cremor Zinci, B.P.C.—(Crem. Zinc.)—Zinc Cream. Zinc oxide, about 1 in 3, with wool fat, almond oil and solution of calcium hydroxide.

Emplastrum Zinci Oxidi, B.P.C.—(Emp. Zinc. Oxid.)—Zinc Oxide Plaster. It is spread with rubber adhesive compound containing not less than 20 per cent. of zinc oxide.

Gelatinum Zinci, B.P.—(Gelat. Zinc.)—Gelatin of Zinc. *Syn.*—Unna's Paste. Zinc oxide, 15 per cent., with gelatin, glycerin and water.

This gelatin, prepared with a larger proportion of glycerin, was included in the British Pharmaceutical Codex, 1923, under the name of Pasta Zinci et Gelatini.

Gelatinum Zinci et Ichthammolis, B.P.C.—(Gelat. Zinc. et Ichtham.)—Gelatin of Zinc and Ichthammol. *Syn.*—Pasta Zinci et Ichthammolis; Unna's Paste with Ichthammol. Ichthammol, about 2 per cent., with zinc oxide, glycerin, gelatin and distilled water.

Ligamentum Pastæ Zinci, B.P.C.—(Ligament. Past. Zinc.)—Zinc Paste Bandage. It is prepared with a paste containing 17 per cent. of zinc oxide.

Linimentum Calaminæ Compositum, B.P.C.—(Lin. Calamin. Co.)—Compound Liniment of Calamine. Calamine, 1 in 10, with zinc oxide, zinc oleostearate, wool fat, white soft paraffin, and liquid paraffin.

Pasta Picis Carbonis, B.P.C.—(Past. Pic. Carbon.)—Coal Tar Paste. Coal tar, about 3.5 per cent., with compound paste of zinc oxide.

Pasta Resorcinolis, B.P.C.—(Past. Resorcin.)—Resorcinol Paste. *Syn.*—Pasta Resorcini; Resorcin Paste; Lassar's Stronger Resorcin Paste. Resorcinol, zinc oxide and starch, of each about 20 per cent., with liquid paraffin.

Pasta Resorcinolis Mitis, B.P.C.—(Past. Resorcin. Mit.)—Mild Resorcinol Paste. *Syn.*—Pasta Resorcini Mitis; Mild Resorcin Paste, Lassar's Mild Resorcin Paste. Resorcinol, about 10 per cent., zinc oxide and starch, of each about 25 per cent., with liquid paraffin.

Pasta Zinci Oxidi Composita, B.P.—(Past. Zinc. Oxid. Co.)—Compound Paste of Zinc Oxide. *Syn.*—Zinc Paste. Zinc oxide, 25 per cent., with starch and white soft paraffin.

Pasta Zinci Oxidi cum Acido Salicylico, B.P.C.—(Past. Zinc. Oxid. c. Acid. Salicyl.)—Paste of Zinc Oxide with Salicylic Acid. *Syn.*—Lassar's Paste. Salicylic acid, 2 per cent., with zinc oxide, starch and white soft paraffin.

Pilulæ Zinci Oxidi et Belladonnæ, B.P.C.—(Pil. Zinc. Oxid. et Bellad.)—Zinc Oxide and Belladonna Pills. Each pill contains 2 grains of zinc oxide and $\frac{1}{4}$ grain of dry extract of belladonna. Dose.—1 pill.

Pulvis Zinci et Acidi Borici, B.P.C.—(Pulv. Zinc. et Acid. Boric.)—Zinc and Boric Acid Powder. Equal parts of zinc oxide and boric acid.

Pulvis Zinci et Acidi Salicylici, B.P.C.—(Pulv. Zinc. et Acid. Salicyl.)—Zinc and Salicylic Acid Powder. Zinc oxide, 1 in 5, and salicylic acid, 1 in 20, with starch.

Pulvis Zinci et Amyli, B.P.C.—(Pulv. Zinc. et Amyli.)—Zinc and Starch Powder. Equal parts of zinc oxide and starch.

Pulvis Zinci et Amyli Compositus, B.P.C.—(Pulv. Zinc. et Amyli Co.)—Compound Zinc and Starch Powder. Equal parts of zinc oxide, starch, boric acid and purified talc, perfumed with oil of geranium.

Suppositorium Hamamelini et Zinci Oxidi, B.P.C.—(Supp. Hamamel. et Zinc. Oxid.)—Hamamelin and Zinc Oxide Suppository. Each suppository weighs 30 grains (2 grammes) and contains 3 grains of dry extract of hamamelis and 10 grains of zinc oxide.

Unguentum Hydrargyri Ammoniati et Zinci Oxidi, B.P.C.—(Ung. Hydrarg. Ammon. et Zinc. Oxid.)—Ammoniated Mercury and Zinc Oxide Ointment. Ointment of ammoniated mercury and ointment of zinc oxide, equal parts.

Unguentum Hydrargyri, Plumbi et Zinci, B.P.C.—(Ung. Hydrarg. Plumb. et Zinc.)—Mercury, Lead and Zinc Ointment. *Syn.*—Unguentum Metallorum. Ointment of mercuric nitrate, ointment of lead subacetate and ointment of zinc oxide, equal parts.

Unguentum Zinci cum Balsamo Peruviano, B.P.C.—(Ung. Zinc. c. Bals. Peruv.)—Zinc Ointment with Balsam of Peru. Balsam of Peru, about 11 per cent., in ointment of zinc oxide and ointment of boric acid.

Unguentum Zinci cum Benzoino, B.P.C.—(Ung. Zinc. c. Benzoin.)—Ointment of Zinc Oxide with Benzoin. Compound tincture of benzoin, about 12·5 per cent. v/w, in ointment of zinc oxide.

Unguentum Zinci et Olei Ricini, B.P.C.—(Ung. Zinc. et Ol. Ricin.)—Zinc and Castor Oil Ointment. Zinc oxide and castor oil in benzoinated lard. It is of the same composition as a mixture of equal weights of castor oil and the zinc ointment of the British Pharmacopœia, 1914.

Unguentum Zinci et Olei Ricini cum Benzoino, B.P.C.—(Ung. Zinc. et Ol. Ricin. c. Benzoin.)—Zinc and Castor Oil Ointment with Benzoin. Zinc oxide, castor oil and compound tincture of benzoin, with benzoinated lard. The proportions of zinc oxide and benzoinated lard are equivalent to about 40 per cent. of the zinc ointment of the British Pharmacopœia, 1914.

Unguentum Zinci Morrhuatæ, B.P.C.—(Ung. Zinc. Morrh.)—Zinc Morrhuate Ointment. Cod-liver oil, about 14 per cent., and zinc oxide, about 32 per cent., with solution of calcium hydroxide, purified talc and balsam of Peru, in beeswax, wool fat and white soft paraffin.

Unguentum Zinci Oxidi, B.P.—(Ung. Zinc. Oxid.)—Ointment of Zinc Oxide. *Syn.*—Unguentum Zinci; Zinc Ointment. Zinc oxide, 15 per cent., in simple ointment.

ZINCI PERMANGANAS

(Zinc. Permang.)

Zinc Permanganate

Zinc permanganate, $\text{Zn}(\text{MnO}_4)_2, 6\text{H}_2\text{O}$, may be prepared by adding a concentrated solution of barium permanganate to a concentrated solution of zinc sulphate until a precipitate of barium sulphate ceases to form. The precipitate is separated, the clear solution evaporated carefully at a low temperature to crystallisation, or *in vacuo* over sulphuric acid, and the crystals finally dried at about 40°. It occurs in the form of dark brown, nearly black, iridescent, deliquescent crystals. When heated slowly it loses water and oxygen, leaving a residue of zinc manganate. Zinc permanganate gives up oxygen more readily than does the potassium salt, hence great care should be taken in bringing it in

contact with easily oxidisable substances. It should be **stored** in well-closed bottles and protected from light.

Soluble in water (1 in 3), generally leaving a slight residue.

Standard.—Zinc permanganate contains not less than 90 per cent. of $\text{ZnMn}_2\text{O}_8 \cdot 6\text{H}_2\text{O}$. Boil 1 gramme with 10 millilitres of hydrochloric acid until chlorine ceases to be evolved, dilute to 30 millilitres with water and add 1 millilitre of dilute sulphuric acid; no turbidity is produced within five minutes (limit of barium).

Assay.—Dissolve about 0.15 gramme, accurately weighed, in water, filter through asbestos, and acidify the filtrate with 5 millilitres of dilute sulphuric acid; warm to 60° , add 50 millilitres of N/10 oxalic acid, and titrate the excess with N/10 potassium permanganate; each millilitre of N/10 oxalic acid is equivalent to 0.004113 gramme of $\text{ZnMn}_2\text{O}_8 \cdot 6\text{H}_2\text{O}$.

Action and Uses.—Zinc permanganate resembles the potassium salt in its oxidising properties, but is more astringent. It is used chiefly in urethritis (1 gran in 8 fluid ounces), either as an injection or as a urethral douche. The **incompatibles** of zinc permanganate are those of potassium permanganate, but the former is even more readily reduced by contact with organic matter.

ZINCI PHENOLSULPHONAS

(Zinc. Phenolsulphon.)

Zinc Phenolsulphonate

Synonym—Zinc Sulphocarbolate.

Zinc phenolsulphonate, $(\text{C}_6\text{H}_4(\text{OH})\text{SO}_3)_2\text{Zn} \cdot 8\text{H}_2\text{O}$, may be prepared by decomposing a solution of the barium salt with the exact equivalent of zinc sulphate, whereby barium sulphate is precipitated while zinc phenolsulphonate remains in solution and is obtained by evaporation and crystallisation. Zinc phenolsulphonate occurs in the form of colourless, transparent, rhombic prisms or tabular crystals, which may become slightly pink on exposure to light and air; it is efflorescent and usually odourless, but sometimes has a faint odour of phenol. The aqueous solution is acid to litmus. On heating at 100° , it loses 6 molecules of water of crystallisation, and the remainder is lost at 125° ; at higher temperatures it chars, emitting inflammable vapours having the odour of phenol, and finally leaving a residue of zinc sulphate.

Soluble in water (1 in 2), boiling water (3 in 1), alcohol (1 in 2.5) and boiling alcohol (2 in 1).

Standard.—Zinc phenolsulphonate, determined by the method of the British Pharmacopœia for Zinci Sulphas, contains not less than 99.5 per cent. of $\text{C}_{12}\text{H}_{10}\text{O}_8\text{S}_2\text{Zn} \cdot 8\text{H}_2\text{O}$; each millilitre of M/5 potassium iodate is equivalent to 0.01852 gramme of $\text{C}_{12}\text{H}_{10}\text{O}_8\text{S}_2\text{Zn} \cdot 8\text{H}_2\text{O}$.

Arsenic limit, 5 parts per million. 2 grammes complies with the limit test for sulphates.

Action and Uses.—Zinc phenolsulphonate is rarely given internally. Externally, it has been employed as an astringent and antiseptic injection in leucorrhœa and gonorrhœa (3 grains to 1 fluid ounce), and as a spray for the throat and nose (5 grains to 1 fluid ounce). It has an action similar to that of zinc sulphate, but is somewhat more antiseptic.

ZINCI PHOSPHIDUM

(Zinc. Phosphid.)

Zinc Phosphide

Zinc phosphide may be prepared in small amounts only by heating phosphorus with finely powdered metallic zinc. For the preparation on a larger scale, the vapours of phosphorus are led over fused zinc in a current of dry hydrogen. It occurs as dark grey, minutely crystalline fragments with a metallic lustre, or as a steel-grey, crystalline powder having a slight odour of phosphorus, but emitting it more strongly when triturated. The powder has the appearance of reduced iron and a slight taste of phosphorus. Out of contact with air it melts at a higher temperature than zinc and sublimes unchanged, condensing in needles, but when heated in the presence of air it is oxidised to zinc phosphate.

Insoluble in water and alcohol; soluble in acids, with evolution of hydrogen phosphide which is not spontaneously inflammable; by nitric acid it is converted into zinc phosphate.

Standard.—Zinc phosphide contains not less than 70 per cent. of Zn_3P_2 . The gas evolved on the addition of excess of dilute sulphuric acid is completely absorbed by a strong solution of copper nitrate (absence of free zinc).

Assay.—Place about 0.25 gramme, accurately weighed, in a flask fitted with a funnel provided with a stop-cock and connected with a suitable absorption apparatus containing silver nitrate solution; pass a current of carbon dioxide through the apparatus, pour a mixture of 20 millilitres of water and 50 millilitres of 2N sulphuric acid through the funnel and, after the initial reaction has subsided, gently warm the flask for thirty minutes; transfer the silver nitrate solution to a beaker, add a slight excess of hydrochloric acid and filter the solution; determine the phosphoric acid in the filtrate as magnesium pyrophosphate; 1 gramme of magnesium pyrophosphate is equivalent to 1.159 gramme of Zn_3P_2 .

Action and Uses.—Zinc phosphide possesses the properties of free phosphorus. Being very stable, and not liable to oxidation by trituration, it is well adapted for **administration** in pills. Acid

vegetable extracts should not be used with zinc phosphide since they may cause the evolution of hydrogen phosphide.

Dose.—0.003 to 0.016 gramme ($\frac{1}{30}$ to $\frac{1}{4}$ grain).

ZINCI STEARAS

(Zinc. Stear.)

Zinc Stearate

Zinc stearate may be prepared by the interaction of zinc sulphate and curd soap by a method similar to that described for Zinc Oleostearas. It consists chiefly of zinc stearate, $(C_{17}H_{35}COO)_2Zn$, but contains also a variable proportion of zinc palmitate, $(C_{16}H_{31}COO)_2Zn$, and usually a small amount of zinc oleate, $(C_{17}H_{33}COO)_2Zn$. Zinc stearate occurs as a light, white, impalpable, amorphous powder free from gritty particles, and having a slight, characteristic odour. When boiled with dilute hydrochloric acid, the fatty acids are liberated and form an oily layer on the surface of the liquid. On heating it melts, and at a higher temperature it decomposes with evolution of inflammable vapours and the odour of burning fat, leaving finally a residue of zinc oxide.

Insoluble in water, alcohol (90 per cent.) and ether.

Standard, B.P.—Zinc stearate contains zinc equivalent to not less than 13 per cent. and not more than 15.5 per cent. of ZnO. It is neutral to litmus, and complies also with limit tests for alkalis and alkaline earths, free fatty acids and sulphate.

Action and Uses.—Zinc stearate is recommended as a soothing and mildly antiseptic preparation for acne, eczema and other skin affections. It is used either alone, or combined with other powders, for purposes similar to those for which zinc oleostearate is used.

ZINCI SULPHAS

(Zinc. Sulph.)

Zinc Sulphate

Zinc sulphate may be obtained by dissolving zinc in dilute sulphuric acid or by roasting zinc blende, a native zinc sulphide, in air, extracting the product with water and crystallising from the resulting solution. It occurs in colourless, odourless, somewhat efflorescent, transparent crystals or as a crystalline powder, having an astringent, metallic taste. The aqueous solution is acid to litmus, but not to methyl orange. When gradually heated to 50°, it loses 5 molecules of its water of crystallisation, or 31.2 per cent. of its weight, without melting; at 100° it loses another molecule, and the last molecule is lost at about 248°, with decomposition, sulphur dioxide and oxygen being evolved

and a residue of zinc oxide remaining. Zinc sulphate is isomorphous with magnesium sulphate. Crude zinc sulphate is sometimes known as "white vitriol" or "white copperas."

Soluble in water (1 in 0.7), boiling water (1 in 0.2); insoluble in alcohol (90 per cent.).

Standard, B.P.—Zinc sulphate contains not less than 99.5 per cent. and not more than the equivalent of 101 per cent. of $\text{ZnSO}_4 \cdot 7\text{H}_2\text{O}$. Arsenic limit, 5 parts per million. It complies also with limit tests for acidity, for copper, aluminium, nickel, manganese and magnesium, and for chloride and iron.

Action and Uses.—Zinc sulphate is now rarely administered internally except as a reflex emetic. For this purpose doses up to 2 grammes (30 grains) are required. It is especially useful as an emetic in narcotic poisoning, but it must not be given for its emetic action in the presence of much chloride, since zinc chloride may be formed and ulceration may ensue. Zinc sulphate is used externally principally as an astringent lotion for indolent ulcers and to assist granulation. Such lotions are also employed to relieve chronic inflammation of mucous membranes in gonorrhœa and conjunctivitis. For the latter purpose, $\frac{1}{2}$ to 1 grain in 1 fluid ounce of water is commonly employed. Solutions of zinc sulphate are used for ionisation. Zinc sulphate is **incompatible** with alkali carbonates and hydroxides, and with astringent infusions and decoctions. In cases of **poisoning**, the procedure described under *Zinci Chloridum* should be followed.

Dose.—As an astringent, 0.06 to 0.2 gramme (1 to 3 grains); as an emetic, 0.6 to 2 grammes (10 to 30 grains).

Preparations

Collyrium Acidi Borici et Zinci, B.P.C.—(*Collyr. Acid. Boric. et Zinc.*)—Boric Acid and Zinc Eye Lotion. Each fluid ounce contains about 4 grains of boric acid and 1 grain of zinc sulphate in distilled water.

Lotio Rubra, B.P.C.—(*Lot. Rub.*)—Red Lotion. *Syn.*—Red Wash. Zinc sulphate, about 0.45 per cent. w/v, with compound tincture of lavender and distilled water.

Pulvis Zinci Sulphatis Compositus, B.P.C.—(*Pulv. Zinc. Sulph. Co.*)—Compound Zinc Sulphate Powder. *Syn.*—*Pulvis Acidi Borici Compositus*; Compound Boric Acid Powder; *Pulvis Antisepticus Solubilis*; Soluble Antiseptic Powder. Zinc sulphate, 1 in 8, with eucalyptol, menthol, phenol, salicylic acid, thymol and boric acid.

ZINCI VALERIANAS

(*Zinc. Valer.*)

Zinc Valerianate

Synonym—Zinc Valerate.

Zinc valerianate, $\text{Zn}(\text{C}_5\text{H}_9\text{O}_2)_2 \cdot 2\text{H}_2\text{O}$, may be prepared by mixing hot solutions of sodium valerianate and zinc sulphate, or by saturating

valerianic acid with zinc carbonate, the product being dried at a low temperature. It occurs in the form of white, lustrous, pearly scales or as a white powder, having the odour of valerianic acid and a sweet, astringent and metallic taste. Zinc valerianate may also be obtained anhydrous or containing only one molecule of water of crystallisation, according to the method of preparation. The aqueous solution is slightly acid to litmus and, when boiled, becomes turbid from loss of valerianic acid and formation of a basic salt. On exposure to air the salt slowly loses valerianic acid. It should be **stored** in well-stoppered bottles.

Soluble in water (1 in 120), alcohol (1 in 60) and ether (1 in 500).

Standard.—Zinc valerianate yields, on treatment with nitric acid and subsequent gentle ignition, not less than 25 per cent. and not more than 28 per cent. of ZnO . Arsenic limit, 5 parts per million. The residue from 5 grammes complies with the limit test for lead in *Zinci Oxidum*. 0.5 gramme complies with the limit test for sulphates.

Action and Uses.—Zinc valerianate has been administered in pill form in the treatment of hysteria and other nervous disorders, often in combination with valerianates of quinine and iron, or with compound galbanum pill.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

AMMONII VALERIANAS.—Ammonium valerianate occurs in colourless, very deliquescent crystals having an odour of valerianic acid. The commercial salt is usually an acid salt containing ammonia equivalent to only about 35 per cent. of $\text{C}_4\text{H}_9\cdot\text{COONH}_4$. It should be stored in well-stoppered bottles. It is soluble in water and alcohol. Ammonium valerianate has been given for the same purposes as the zinc salt. It may be administered in neutral solution, with the addition of orange flower water to mask its disagreeable taste and odour. Dose.—0.12 to 0.5 gramme (2 to 8 grains).

Preparation

Pilulæ Ferri Valerianatis Compositæ, B.P.C.—(Pil. Ferr. Valer. Co.)—Compound Iron Valerianate Pills. *Syn.*—Pilulæ Trium Valerianatum. Each pill contains 1 grain each of the valerianates of iron, quinine and zinc. Dose.—1 or 2 pills.

ZINGIBER

(Zingib.)

Ginger

Ginger consists of the rhizome of *Zingiber officinale* Roscoe (Fam. Zingiberaceæ), scraped to remove the dark outer layer and dried in the sun. It is known in commerce as unbleached Jamaica ginger. Ginger is indigenous to Asia, but is cultivated in the West Indies, Africa, Java and other tropical countries. The procedure in Jamaica is to dig up the sympodially branching, horizontally growing rhizome after the aerial parts have died down, wash, peel with a narrow-bladed knife, again wash, and dry in the sun.

Ginger occurs in laterally-flattened, branched rhizomes known as "races" or "hands," about 7 to 15 centimetres long, 1.5 to 6.5 (usually 3 to 4) centimetres high, and 1 to 1.5 centimetres wide; the branches, known as "fingers," arise from the upper surface of the rhizome, widen, contract, and terminate in a stem-scar; they average about 2 centimetres in length. Externally, the rhizome is buff-coloured, striated longitudinally and somewhat fibrous due to the leaf traces exposed by the scraping. The fracture is short, with projecting fibres. The smoothed, transverse surface exhibits under a lens numerous yellow oil cells and scattered vascular bundles, and an endodermis separating the narrow cortex from the wide stele. The odour is agreeable and aromatic and the taste is strongly pungent.

The diagnostic **microscopical** characters are the thin-walled cells of the ground tissue containing abundant starch grains, which are single, ovate to sub-rectangular, up to 40 microns long, 25 microns wide and 7 microns thick, with the hilum in a slight terminal beak; the spiral or reticulate vessels, which give no characteristic reaction for lignin and are often accompanied by narrow, dark brown pigment cells; the sub-spherical oil cells with suberised walls; the absence of cork, sclerenchymatous cells and calcium oxalate crystals.

Ginger **contains** from about 1 to 3 per cent. of volatile oil (specific gravity, 0.875 to 0.885; optical rotation, -25° to -45°), in which camphene, phellandrene, zingiberene, cineole, citral and borneol have been detected, and to which it owes its aroma. The pungency of ginger is due to a yellowish, oily body, gingerol, which rapidly loses its pungency when warmed with 2 per cent. w/v sodium hydroxide solution. Gingerol is a mixture of homologous phenolic substances of the formulæ $C_{17}H_{26}O_4$, $C_{18}H_{28}O_5$, etc. Baryta water splits it up into fatty aldehydes, especially *n*-heptaldehyde and zingerone (4-hydroxy 3-methoxyphenylethylmethylketone). The latter is crystalline and pungent. Ginger also contains shogaol, resin and much starch.

Substitutes.—Jamaica ginger is sometimes limed to whiten it, and is then known as "limed" ginger. Cochin and Calcut gingers are in smaller "hands," and the branches are usually shorter and thicker; they are often imported only partly scraped ("unscraped" or "coated"), and may be bleached (limed) or unbleached. African ginger is more pungent (alcohol-soluble extractive about 5 to 8 per cent.), but less aromatic; it is usually small, dark and coated, but may also be found limed. Japanese ginger is commonly in small, flattened pieces; many of the starch grains are compound, and the oil differs in its physical character (specific gravity, about 0.894; optical rotation, about $+9^{\circ}$), these particulars indicating that it is not produced by *Zingiber officinale*; it has been referred to *Z. Mioga* Roscoe. Ground ginger is often adulterated with exhausted ("spent") ginger, a sophistication that may be detected by a diminution in the ash soluble in water, as well as by the yields of alcohol- and water-soluble extractive.

Standard, B.P.—Ginger yields to alcohol (90 per cent.) not less than 4.5 per cent. of extractive, and to water not less than 10 per cent. of extractive. Ash, not more than 6 per cent. Water-soluble ash, not less than 1.7 per cent.

Ginger, in powder (*Pulvis Zingiberis*: *Pulv. Zingib.*), contains the constituents and possesses the diagnostic microscopical characters of

Zingiber, and complies with the limit for alcohol-soluble extractive, water-soluble extractive, ash and water-soluble ash of the unground drug.

Action and Uses.—Ginger has carminative properties and is chiefly used as a stomachic and as a flavouring agent. For this reason it is often prescribed with sodium bicarbonate, and is sometimes added to purgative medicines to prevent griping. Ginger is **administered** as *Tinctura Zingiberis Fortis*, *Tinctura Zingiberis Mitis*, or as *Syrupus Zingiberis*, generally in mixture form. The strong tincture is often taken on a lump of sugar. For use in pills or tablets, *Oleoresina Zingiberis* is suitable.

Dose.—0·3 to 1 gramme (5 to 15 grains).

Preparations

Oleoresina Zingiberis, B.P.C.—(*Oleores. Zingib.*)—Oleoresin of Ginger. *Syn.*—Gingerin. The acetone-soluble matter of ginger. Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain).

Syrupus Zingiberis, B.P.—(*Syr. Zingib.*)—Syrup of Ginger. Strong tincture of ginger, 5 per cent. v/v, in syrup. Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Tabellæ Zingiberis Compositæ, B.P.C.—(*Tab. Zingib. Co.*)—Compound Tablets of Ginger. *Syn.*—Ginger Mint Tablets. Each tablet contains 5 grains of sodium bicarbonate and $\frac{1}{10}$ grain of oleoresin of ginger, with ammonium bicarbonate, saccharin and $\frac{1}{8}$ minim of oil of peppermint. Dose.—1 or 2 tablets.

Tinctura Zingiberis Fortis, B.P.—(*Tinct. Zingib. Fort.*)—Strong Tincture of Ginger. *Syn.*—Essence of Ginger. 1 in 2, by percolation with alcohol (90 per cent.). Dose.—0·3 to 0·6 millilitre (5 to 10 minims).

Tinctura Zingiberis Mitis, B.P.—(*Tinct. Zingib. Mit.*)—Weak Tincture of Ginger. Strong tincture of ginger, 20 per cent. v/v, in alcohol (90 per cent.). Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

PART II
SURGICAL DRESSINGS

The British Pharmaceutical Codex

PART II

SURGICAL DRESSINGS

Surgical dressings include bandages, gauzes, lints, plasters, tissues, towels, wools and various protectives. In the specifications a number of technical terms are used, the meanings of which are as follows:—**Yarn** consists of cotton, wool, or other fibres, spun and prepared for use in weaving. **Warp** is the term applied to the threads that run the long way of the fabric, that is, longitudinally, and **weft** to those that run the short way, that is, transversely. **Fineness** or **count** of yarn, in cotton, refers to the number of hanks, each of 840 yards, that make up one pound weight of such yarn, and in wool, signifies the number of hanks, each of 560 yards, that make up one pound weight; thus “thirty-sixes” in cotton means that 36 hanks, as described, weigh one pound. **Foreign matter** is the name given to the non-fibrous materials which are often found in a fabric. In fabrics which have not been subjected to any finishing process, this foreign matter is usually referred to as “size”, and in the finished cloth as “filling”. Size is applied to the warp primarily to reduce chafing in the loom, but substances are often added to the size in order to increase the weight of the cloth. Filling is not added for sizing purposes, but is applied to the cloth to give a desired finish or to increase the weight. Substances commonly used in sizing are wheat flour, potato, maize and sago starches, together with softening agents such as tallows, oils and waxes, or glycerin. When it is required to add weight to the warp yarn, and consequently to the ultimate cloth, china clay, magnesium chloride, etc., may be added. In order to prevent mildew, an antiseptic such as zinc chloride is sometimes used. Substances used for filling purposes include most of the above, also other starches, dextrin, and magnesium and sodium sulphates. **Neps** are small tangled masses of cotton fibres, the result of imperfect growth, or produced in manufacture. The term **moisture regain** is used to denote the percentage of moisture to be added to the dried material to adjust the weight to that of the material of normal moisture content.

The **Sterilisation** of surgical dressings may be effected by the methods described in Appendix XII.

Moisture, water-soluble extractive, foreign matter, cotton and wool in fabrics and unmedicated dressings are determined by the following methods:—

Moisture.—Weigh accurately about 5 grammes of the dressing, and dry at 100°; the loss in weight is moisture.

Water-soluble Extractive.—The dried sample from the moisture determination is boiled in water for a period of five minutes, and the operation is repeated six times; the washed residue is then dried at 100° and weighed. The loss in weight is the water-soluble extractive.

Foreign Matter.—The dried sample from the moisture determination is boiled twice for periods of five minutes in water to remove soluble salts. Tallow, oils, or waxes are removed by treatment with a boiling solution of a neutral soap, or by extraction with a suitable grease solvent. Starch, if present, is removed by treatment at about 50° with a solution of malt extract and subsequent boiling in water. Insoluble matter, such as china clay, if present, is removed by continual agitation and squeezing of the sample in numerous wash waters. All the solutions and wash waters used are passed through a fine sieve, and any loose threads or fibres added to the residue, which is then dried at 100° and weighed. The loss in weight is foreign matter. In the case of grey unbleached cotton, an allowance of 3 per cent. is made for loss of natural impurities by the above treatment. An ash determination is made upon a portion of the cleaned sample in order to ascertain whether all insoluble matter has been removed, and a correction of 0.2 per cent. is allowed for the natural ash of cotton.

Cotton and Wool.—The dried material from the determination of foreign matter is placed in a boiling 5 per cent. w/v solution of sodium hydroxide in water, and boiled for about ten minutes. The residue is then removed and given a further similar treatment. It is next well washed with water until free from alkali. All the solutions and wash waters used are passed through a fine sieve, and any loose threads or fibres added to the residue, which is then dried at 100° and weighed. In the case of unbleached cotton, an addition of 4 per cent. is made to this weight to allow for the loss of natural constituents of the cotton which occurs with the sodium hydroxide treatment. The weight thus obtained is that of the dry cotton, and the difference between this figure and that of the dried material from the foreign matter determination is the weight of the dry wool. To the weights of dry cotton and dry wool standard moisture regains of 8.5 and 16 per cent., respectively, are added.

BATTISTA

.(Battist.)

Battiste

Battiste consists of a bleached cotton fabric of plain weave, evenly proofed on both sides by treatment with rubber solution so that the material is impervious to water. The surface is non-adhesive. It is "heat vulcanised" and not "cold cured," free from resins and acidity, and does not become acid when stored.

Standard.—Battiste, when boiled with water for thirty minutes, or when subjected to steam in a steriliser for twenty minutes at a pressure of 15 pounds per square inch, does not become sticky or show any appreciable deterioration. Weight per square yard, not less than 5 ounces; weight of the fabric per square yard, after the removal of the proofing and other foreign matter and correcting for the natural moisture regain, not less than 2 ounces. The difference between the weight per square yard of the battiste and the weight of the fabric is not less than 3 ounces. Average number of threads per inch, not less than 104 in the warp and not less than 72 in the weft. The component yarns are of good uniform grade, and the material is reasonably free from weaving defects.

CARBASUS ABSORBENS

(Carbas. Absorb.)

Absorbent Gauze

Synonym—Unmedicated Gauze.

Absorbent gauze consists of cotton cloth of plain weave. It is supplied 36 inches wide and in various lengths. Waxed paper should not be used for wrapping absorbent gauze, since it reduces the absorbency of the material. Its absorbency may also be reduced considerably by medication. Aseptic absorbent gauze is absorbent gauze in a sterile condition. It may be **sterilised** as described in Appendix XII, and should be sealed in containers suitable for maintaining the gauze in a sterile condition.

Standard.—Absorbent gauze is composed of yarns of good medium, uniform grade, and the material is well bleached to a good white, clean, free from added foreign matter, and reasonably free from leaf and shell. Water-soluble extractive, not more than 0.5 per cent. Weight per square yard, not less than 180 grains. Average number of threads per inch, not less than 19 in the warp and not less than 15 in the weft. 1 gramme, free from selvedge, compressed to a volume of about 20 millilitres and placed lightly by means of a forceps on the surface of water at about 20°, becomes saturated within ten seconds.

CARBASUS ABSORBENS IN TÆNIA

(Carbas. Absorb. in Tæn.)

Absorbent Ribbon Gauze

Synonym—Unmedicated Ribbon Gauze.

Absorbent ribbon gauze consists of cotton cloth of plain weave. It is supplied in ribbons, of various widths and lengths, having fast

selvedge edges and wound on spools or packed in bottles. Aseptic absorbent ribbon gauze is absorbent ribbon gauze in a sterile condition. It may be **sterilised** as described in Appendix XII, and should be sealed in containers suitable for maintaining the gauze in a sterile condition.

Standard.—Absorbent ribbon gauze is composed of yarns of good medium, uniform grade, and the material is well bleached to a good white, clean, free from added foreign matter, and reasonably free from leaf and shell. Water-soluble extractive, not more than 0.5 per cent. Weight of a piece 2 inches wide and 6 yards long, not less than 190 grains, and the weights of other widths in proportion. Average number of threads per inch, not less than 30 in the warp and not less than 25 in the weft. 1 gramme, when tested for absorbency as described under Carbasus Absorbens, becomes saturated within ten seconds.

CARBASUS ACIDI BORICI

(Carbas. Acid. Boric.)

Boric Acid Gauze

Synonym—Boric Gauze.

Boric acid gauze is absorbent gauze impregnated with boric acid, and may be prepared by immersing absorbent gauze in a sufficient quantity of a saturated solution of boric acid in boiling distilled water lightly tinted pink with a suitable dye, removing the material from the solution, pressing sufficiently to produce a gauze which, when dried, is absorbent, uniformly medicated as far as possible, and contains from 10 to 20 per cent. of boric acid. Boric acid ribbon gauze, varying in width from $\frac{1}{4}$ inch to 2 inches, may be prepared in a similar manner from absorbent ribbon gauze. Boric acid gauze should be **packed** in sealed packets, doubly wrapped.

Standard.—Boric acid gauze contains not less than 10 per cent. and not more than 20 per cent. of H_3BO_3 .

Assay.—Place in a stoppered bottle a quantity of gauze equivalent to about 0.25 square yard in area, accurately weighed. Add 50 millilitres of hot, freshly boiled water and 40 millilitres of glycerin, shake thoroughly, cool, and titrate with N/1 sodium hydroxide, using phenolphthalein or phenol violet as indicator; each millilitre of N/1 sodium hydroxide is equivalent to 0.06184 gramme of H_3BO_3 .

CARBASUS CHLORAMINÆ

(Carbas. Chloram.)

Chloramine Gauze

Chloramine gauze is absorbent gauze impregnated with chloramine, and may be prepared by immersing absorbent gauze in a sufficient

quantity of an aqueous solution of chloramine, removing the material from the solution, and pressing sufficiently to produce a gauze which, when dried, is absorbent, uniformly medicated as far as possible, and contains from 4 to 6 per cent. of chloramine. It should be **packed** in sealed packets, doubly wrapped, and stored in a cool place.

Standard.—Chloramine gauze contains not less than 4 per cent. and not more than 6 per cent. of $C_7H_7O_2NCISNa, 3H_2O$.

Assay.—Place in a stoppered bottle a quantity of gauze equivalent to about 0.25 square yard in area, accurately weighed, with 100 millilitres of water, and shake well; add 20 millilitres of solution of potassium iodide, mix, and add 5 millilitres of dilute sulphuric acid. Shake, allow to stand for ten minutes, and titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.01408 gramme of $C_7H_7O_2NCISNa, 3H_2O$.

CARBASUS EUFLAVINÆ

(Carbas. Euflavin.)

Euflavine Gauze

Euflavine gauze is absorbent gauze impregnated with euflavine, and may be prepared by immersing absorbent gauze in a sufficient quantity of a solution of euflavine, removing the material from the solution, and pressing sufficiently to produce a gauze which, when dried, is absorbent, uniformly medicated as far as possible, and contains about 0.1 per cent. of euflavine. It should be **packed** in sealed packets, doubly wrapped.

CARBASUS HYDRARGYRI ET ZINCI CYANIDI

(Carbas. Hydrarg. et Zinc. Cyanid.)

Mercury and Zinc Cyanide Gauze

Synonym—Double Cyanide Gauze.

Mercury and zinc cyanide gauze is absorbent gauze impregnated with mercury and zinc cyanide, and may be prepared by immersing absorbent gauze in a suspension of mercury and zinc cyanide in water. The suspension is made by mixing cold solutions of zinc potassium cyanide and mercuric chloride, washing the precipitate till the washings are nearly free from mercury, and diffusing the precipitate in water tinted with a suitable purple dye and containing about 1 per cent. of glycerin. The absorbent gauze is placed in the mixture and, by pressing and agitating, the insoluble medicament is uniformly diffused over the gauze, which is then dried. Mercury and zinc cyanide ribbon gauze, from $\frac{1}{4}$ inch to 2 inches in width, may be prepared in the same manner from absorbent ribbon gauze. Mercury and zinc cyanide gauze is not

so absorbent as other medicated gauzes, even when prepared with absorbent gauze of high absorbency. It should be **packed** in sealed packets, doubly wrapped.

Standard.—Mercury and zinc cyanide gauze contains mercury, equivalent to not less than 0·5 per cent. and not more than 1·5 per cent. of $\text{Hg}(\text{CN})_2$, and zinc, equivalent to not less than 1·5 per cent. and not more than 3 per cent. of $\text{Zn}(\text{CN})_2$.

Assay.—Place in a beaker a quantity of gauze equivalent to from 0·5 to 1 square yard in area, accurately weighed, with sufficient water to moisten it thoroughly, and add 30 millilitres of nitric acid. Stir thoroughly, and pour off the solution into a large beaker, pressing out as much liquid as possible from the gauze. Wash the gauze with successive quantities of water and add the washings to the solution. Continue washing until the gauze is free from acid (usually 300 to 400 millilitres is required). Filter, and evaporate to a volume of about 100 millilitres; transfer to a 150 millilitre flask, cool, and adjust the volume to 150 millilitres.

For zinc.—Neutralise 50 millilitres of the solution with dilute solution of ammonia and add 1 drop of dilute nitric acid. Add 15 millilitres of mercuric ammonium thiocyanate solution, and complete the assay by the process of the British Pharmacopœia for Zinci Sulphas; each millilitre of M/5 potassium iodate is equivalent to 0·003913 gramme of $\text{Zn}(\text{CN})_2$.

For mercury.—Wash the remaining 100 millilitres of the solution into a flask with small quantities of water, neutralise with dilute solution of ammonia, make slightly acid with hydrochloric acid and pass in hydrogen sulphide until precipitation is complete; collect the precipitate, wash it with hydrogen sulphide solution until free from acid, then with alcohol and then with carbon disulphide, and dry at 110° ; each gramme of residue is equivalent to 1·0858 grammes of $\text{Hg}(\text{CN})_2$.

CARBASUS HYDRARGYRI PERCHLORIDI

(Carbas. Hydrarg. Perchlor.)

Mercuric Chloride Gauze

Synonym—Sublimate Gauze.

Mercuric chloride gauze is absorbent gauze impregnated with mercuric chloride, and may be prepared by immersing absorbent gauze in a sufficient quantity of a solution of mercuric chloride, removing the material from the solution, and pressing sufficiently to produce a gauze which is absorbent, uniformly medicated as far as possible, and contains, when freshly prepared, about 0·1 per cent. of mercuric chloride. The gauze is liable to considerable variation in strength. It should be **packed** in sealed packets, doubly wrapped.

CARBASUS IODOFORMI

(Carbas. Iodof.)

Iodoform Gauze

Iodoform gauze is absorbent gauze impregnated with iodoform, and may be prepared by immersing absorbent gauze under pressure in ether containing sufficient iodoform to produce a gauze which is absorbent and contains about 5 per cent. of iodoform. When the whole of the liquid is absorbed, and the material uniformly medicated as far as possible, the gauze is removed and the ether allowed to evaporate. No dye must be used in its manufacture. A similar gauze containing about 10 per cent. of iodoform is also prepared, and also a moist gauze prepared with glycerin and containing about 10 per cent. of iodoform. Iodoform ribbon gauze, from $\frac{1}{4}$ inch to 2 inches in width, may be prepared in the same manner from absorbent ribbon gauze. Iodoform gauze should be **packed** in sealed packets, wrapped in transparent cellulose tissue and dark paper externally, and stored in a cool place.

Standard.—Iodoform gauze contains not less than 4 per cent. and not more than 6 per cent. of CHI_3 .

Assay.—Extract a quantity of gauze equivalent to about 0.25 square yard in area, accurately weighed, with sufficient alcohol to produce 100 millilitres, and determine the iodoform in the solution by the process of the British Pharmacopœia for Iodoformum.

CARBASUS PHENOLIS

(Carbas. Phenol.)

Phenol Gauze*Synonym*—Carbolic Gauze.

Phenol gauze is absorbent gauze impregnated with phenol, and may be prepared by immersing absorbent gauze in a sufficient quantity of a solution of phenol in alcohol, removing the material from the solution, and pressing sufficiently to produce a gauze which is absorbent, and contains, when freshly prepared, from 1 to 3 per cent. of phenol. This gauze rapidly loses phenol even when stored under the most favourable conditions, the addition of glycerin being of no value in reducing the rate at which the phenol volatilises. It should be **packed** in sealed packets, doubly wrapped, and stored in a cool place.

In making this preparation the alcohol may be replaced by industrial methylated spirit, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

CARBASUS TRINITROPHENOLIS

(Carbas. Trinitrophen.)

Trinitrophenol Gauze*Synonyms*—Picric Gauze; Picric Acid Gauze.

Trinitrophenol gauze is absorbent gauze impregnated with trinitrophenol, and may be prepared by immersing absorbent gauze in a sufficient quantity of a solution of trinitrophenol in distilled water to produce a gauze which is absorbent, uniformly medicated as far as possible, and contains from 1·5 to 2·5 per cent. of trinitrophenol. No dye must be used in its manufacture. It should be **packed** in sealed packets, doubly wrapped.

Standard.—Trinitrophenol gauze contains not less than 1·5 per cent. and not more than 2·5 per cent. of $C_6H_3O_7N_3$.

Assay.—Place in a stoppered bottle a quantity of gauze equivalent to about 0·25 square yard in area, accurately weighed. Add 100 millilitres of freshly boiled water, shake, and titrate with N/10 sodium hydroxide, using phenolphthalein as indicator; each millilitre of N/10 sodium hydroxide is equivalent to 0·0229 gramme of $C_6H_3O_7N_3$.

CELLULOSUM LIGNI

(Cellulos. Lig.)

Cellulose Wadding

Cellulose wadding is made entirely from high-grade, bleached sulphite pulp, which consists of delignified and disintegrated timber; the fibres of the pulp show the characters of the elements of the timber, usually pine, from which it has been prepared, and give no red or pink colouration with a 1 per cent. alcoholic solution of phloroglucinol followed by hydrochloric acid (distinction from lignified tissue); they give a blue colour with N/50 iodine followed by sulphuric acid, 80 per cent. v/v in water. It should be **stored** in a dry place.

Standard.—Cellulose wadding has a superficial area of not less than 1500 square inches per pound. Moisture, not more than 10 per cent. Ash, not more than 0·5 per cent. It yields to chloroform, by continuous extraction, not more than 1 per cent. of extractive. 1·5 grammes of the material, compressed to a volume of about 20 millilitres and placed lightly by means of a forceps on the surface of water at about 20°, sinks or becomes saturated within five seconds.

CHARTA OLEATA

(Chart. Oleat.)

Oiled Paper

Oiled paper consists of cream or white paper made completely

waterproof by treatment with a suitable drying oil. The paper before oiling should contain not more than 40 per cent. of mechanical wood pulp, and not more than 12 per cent. of mineral matter, and should have a weight of about 30 pounds per ream of 500 sheets measuring 20 by 30 inches.

CORCHORUS

(*Corchor.*)

Jute

Jute consists of the strands of phloem fibres removed from the bark of the stem of *Corchorus olitorus* Linn., *C. capsularis* Linn. and other species of *Corchorus* (Fam. Tiliaceæ), cultivated chiefly in Bengal. It is obtained by retting the stems in water and beating out the fibre. It is pale buff or silvery-grey in tint, the strands having a length of about 1 to 3 metres and a thickness of from 30 to 140 microns, mostly about 80 microns at the middle point. The individual fibres are about 0·8 to 4, or sometimes 5, millimetres long and from 10 to 25 microns wide; the ends are sometimes bluntly pointed and thick-walled, but mostly rounded or even somewhat spatulate; the fibre is smooth, without striations or transverse lines; the lumen varies in diameter, showing contraction at points where the thickness of the wall is correspondingly greater, and here and there being obliterated; the wall responds to the tests for lignin. Jute is supplied on a basis of correct condition weight on a standard moisture regain of 13·75 per cent.

EMPLASTRUM ADHESIVUM

(*Emp. Adhesiv.*)

Rubber Adhesive Plaster

Rubber adhesive plaster consists of bleached cotton cloth of plain weave, in one continuous length and containing no joins, and spread evenly with a plain, brown, rubber adhesive compound of commerce prepared with the best Pará rubber, and containing not more than 25 per cent. of fillers.

Standard.—Rubber adhesive plaster weighs not less than 8 ounces per square yard. Weight of the base cloth, after removal of the adhesive compound and other foreign matter, and correcting for the natural moisture regain, not less than 4 ounces per square yard. The difference between the weight per square yard of the rubber adhesive plaster and the weight of the base cloth is not less than 4 ounces. The cotton cloth is composed of yarns of good uniform grade, and the material is well-bleached to a good white, clean, and free from leaf and shell. Average number of threads per inch, not less than 75 in the warp and not less than 75 in the weft.

EMPLASTRUM ZINCI OXIDI

(Emp. Zinc. Oxid.)

Zinc Oxide Plaster

Zinc oxide plaster consists of bleached cotton cloth of plain weave, in one continuous length and containing no joins, and spread evenly with a rubber adhesive compound of commerce prepared with the best Pará rubber, and containing not less than 20 per cent. of zinc oxide.

Standard.—Zinc oxide plaster weighs not less than 8 ounces per square yard. Weight of the base cloth, after removal of the adhesive compound and other foreign matter, and correcting for the natural moisture regain, not less than 4 ounces per square yard. The difference between the weight per square yard of the plaster and the weight of the base cloth is not less than 4 ounces. The cotton cloth complies with the standard for the cotton cloth described under *Emplastrum Adhesivum*.

GOSSYPIUM ABSORBENS

(Gossyp. Absorb.)

Absorbent Cotton Wool

Synonyms—Absorbent Cotton; Absorbent Wool.

Absorbent cotton wool is prepared from cotton, which consists of the epidermal trichomes of the seeds of *Gossypium herbaceum* Linn. (Fam. Malvaceæ) and other cultivated species of *Gossypium*. The seeds are removed mechanically, and the trichomes freed from fatty matter by treatment with alkali; this is followed by bleaching with chlorinated lime or soda and, after washing, the trichomes are mechanically loosened and separated to form a fleecy mass of soft, white filaments. Each filament consists of a single cell about 2 to 4 centimetres long and 15 to 20 microns wide, forming a flattened, tubular band with slightly thickened, rounded edges, and showing from about 50 to 120 twists per centimetre. The apex of the filament is rounded and often solid. In ammoniacal solution of copper oxide it swells uniformly, without the formation of globular enlargements, and finally dissolves with the exception of the contents of the lumen. It is insoluble in 4.5 per cent. w/v sodium hydroxide solution and is not coloured by a saturated aqueous solution of trinitrophenol. It is soluble in a mixture of 38 volumes of sulphuric acid with 17 volumes of water. Absorbent cotton wool absorbs water readily, but its absorbency may be reduced considerably by medication, the degree of absorbency of the product depending upon the nature of the medicament incorporated. It should be **packed** in sealed packets.

Standard.—Absorbent cotton wool is composed of well-carded, cotton fibres, well-bleached to a good white, free from pieces of

thread, and reasonably free from leaf, shell, fibre, dust and foreign matter. The quality and material is the same throughout, and it offers appreciable resistance when pulled. A thin layer of absorbent cotton wool, equivalent to about 0.5 gramme for an area of 70 square inches, placed between two glass plates and viewed by transmitted light, is not more neppy than the standard sample kept by the Manchester Testing House. 1 gramme of the material compressed to a volume of about 20 millilitres, and placed lightly by means of a forceps on the surface of water at about 20°, sinks or becomes saturated within ten seconds. Average length of staple, not less than $\frac{3}{8}$ inch. Water-soluble extractive, not more than 0.5 per cent. Ash, not more than 0.5 per cent.

GOSSYPIUM ACIDI BORICI

(*Gossyp. Acid. Boric.*)

Boric Acid Wool

Synonym—Boric Wool.

Boric acid wool is absorbent cotton wool impregnated with boric acid, and may be prepared by immersing absorbent cotton wool in a hot, saturated, aqueous solution of boric acid lightly tinted pink with a suitable dye, removing the sheets to wire trays, allowing to drain, and pressing sufficiently to produce a wool which is absorbent and contains from 15 to 30 per cent. of boric acid. It should be **packed** in sealed packets, doubly wrapped.

Standard.—Boric acid wool, determined by the method for *Carbasus Acidi Borici*, using about 5 grammes, accurately weighed, contains not less than 15 per cent. and not more than 30 per cent. of H_3BO_3 .

GOSSYPIUM CAPSICI

(*Gossyp. Capsic.*)

Capsicum Wool

Capsicum wool is absorbent cotton wool impregnated with oleoresin of capsicum, and may be prepared by compressing absorbent cotton wool, and pouring over it a solution of oleoresin of capsicum in alcohol tinted orange-brown with a suitable dye. A solution of 20 grammes of oleoresin in 700 millilitres of alcohol should be used for 900 grammes of wool. It should be **packed** in sealed packets, doubly wrapped.

In making this preparation the alcohol may be replaced by industrial methylated spirit, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

JACONETTUM

(Jacon.)

Jaconet

Jaconet consists of a bleached cotton fabric of plain weave, evenly proofed with rubber on one side so that the material is impervious to water. The surface is non-adhesive. It is "heat vulcanised" and not "cold cured," free from resins and acidity, and does not become acid when stored. Pink jaconet is jaconet coloured with a suitable dye.

Standard.—Jaconet, when boiled with water for thirty minutes, or when subjected to steam in a steriliser for twenty minutes at a pressure of 15 pounds per square inch, does not become sticky or show any appreciable deterioration. Weight per square yard, not less than 6 ounces. Weight of the fabric per square yard, after the removal of the proofing and other foreign matter, and correcting for the natural moisture regain, not less than 2 ounces. The difference between the weight per square yard of the jaconet and the weight of the fabric is not less than 4 ounces. Average number of threads per inch, not less than 104 in the warp and not less than 72 in the weft. The component yarns are of good uniform grade, and the material is reasonably free from weaving defects.

LANA

(Lan.)

Wool

Synonym—Animal Wool.

Wool is prepared from the fleece of the sheep, *Ovis aries* Linn. (Order Ungulata). The fleece is subjected to cleansing and washing to remove wool-grease and foreign substances. Wool consists of sub-cylindrical, solid hairs, about 15 to 60 microns in width. Each hair is composed of a cuticle of imbricated, flattened, epithelial scales, a wide cortex of nucleated, spindle-shaped fibres, and a narrow medulla of polyhedral or rounded cells. The free projecting edges of the epithelial scales are directed towards the apex of the hair, and give rise to numerous irregular, transverse markings upon the surface of the hair. It is soluble in a 4.5 per cent. w/v sodium hydroxide solution at 100°; insoluble in, but coloured blue by, ammoniacal solution of copper oxide; insoluble at ordinary temperatures in a cold mixture of 38 volumes of sulphuric acid with 17 volumes of water. It is stained yellow by a saturated aqueous solution of trinitrophenol. The proportion of wool in mixtures of wool and cotton is determined quantitatively by the process described on page 1136.

LIGAMENTUM CALCII SULPHATIS**(Ligament. Calc. Sulph.)****Plaster of Paris Bandage**

Plaster of Paris bandage consists of bleached cotton cloth of plain weave in one continuous length and containing no joins, impregnated with exsiccated calcium sulphate and suitable adhesives. The exsiccated calcium sulphate is incorporated with the fabric so that at least 75 per cent. of the total weight of the bandage is exsiccated calcium sulphate adherent to the fabric, and the bandage is reasonably free from loose powder. The bandage should be **packed** in a sealed container and **stored** in a dry place.

Standard.—Plaster of Paris bandage measuring 2 inches by 4 yards weighs not less than 2·5 ounces, and the fabric, after removal of the exsiccated calcium sulphate and other foreign matter, weighs not less than 85 grains; the weights of bandages of other widths and lengths are in proportion. Average number of threads per inch, not less than 33 in the warp and not less than 19 in the weft.

LIGAMENTUM CRISPI**(Ligament. Crisp.)****Crêpe Bandage**

Crêpe bandage consists of characteristic fabric of plain weave, in one continuous length and containing no joins, in which the warp threads are of cotton and wool, and the weft threads are entirely of cotton.

Standard.—Crêpe bandage is composed of yarns of a good uniform grade, and the material is clean, free from added foreign matter, and reasonably free from weaving defects. It measures, when fully extended, not less than twice the normal length, the normal length being the length of the unstretched bandage. After being held fully extended for one minute, it returns after lightly shaking for a few seconds to not more than two-thirds of the fully-extended length. The bandage contains not less than 33·3 per cent. by weight of wool, all of which is in the warp. A bandage 3 inches wide, the width being that portion between the fast edges of the unstretched bandage, contains in the warp not less than 47 cotton threads and 94 wool threads and, in addition, 2 two-fold cotton binding threads at each edge, and the number of cotton and wool threads in bandages of other widths are in proportion. The warp threads are arranged as follows:—1 two-fold cotton thread (right twist), 2 wool threads, 1 two-fold cotton thread (reverse twist), 2 wool threads. Count of the wool, not coarser than 25's and not finer than 30's (worsted count). The warp threads are made of two-fold cotton yarn with a finished count, after doubling, not

finer than two-fold 20's, and containing not fewer than 54 folded turns per inch. The weft consists of cotton which is 20's count, and the weft threads number not less than 25 per inch when the bandage is fully stretched. Weight of a bandage 3 inches in width, not less than 617 grains per 5 yards (fully stretched), the weights of bandages of other widths and lengths being in proportion.

LIGAMENTUM DOMETTÆ

(Ligament. Domett.)

Domette Bandage

Domette bandage consists of a union fabric of plain weave, in one continuous length and containing no joins, in which the warp yarns are of cotton and the weft yarns entirely of wool.

Standard.—Domette bandage is composed of yarns of a good medium, uniform grade, and the material is clean. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Proportion of wool, not less than 66.6 per cent. Foreign matter, not more than 2 per cent. Weight of the bandage, not less than 440 grains per 2 inches by 6 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 40 in the warp and not less than 22 in the weft, the total number of threads per square inch being not less than 65.

LIGAMENTUM ELASTICUM ADHESIVUM

(Ligament. Elast. Adhesiv.)

Elastic Adhesive Bandage

Elastic adhesive bandage consists of elastic cotton fabric, spread evenly with a rubber adhesive compound of commerce prepared with the best Pará rubber, and containing not less than 20 per cent. of zinc oxide. It should be packed in sealed containers and **stored** in a cool place.

Standard.—Elastic adhesive bandage measuring 3 inches by 5 yards, when fully stretched, contains not less than 2 ounces of the rubber adhesive compound, and the weights of the adhesive compound on bandages of other widths and lengths are in proportion. The fabric of each bandage measuring 3 inches by 5 yards, when fully stretched, after the rubber adhesive compound and other foreign matter have been completely removed and correction has been made for the natural moisture regain, weighs not less than 1.75 ounces, and the weights of bandages of other widths and lengths are

in proportion. The elasticity is such that, upon immediate release after being fully stretched, the bandage returns to a length not exceeding 80 per cent. of the length when fully stretched. The warp of the fabric, determined by ascertaining the total number of warp threads in the bandage and dividing this number by the width of the unstretched bandage in inches, contains not fewer than 44 threads per inch. The warp threads are made of two-fold cotton yarn with a finished count, after doubling, not finer than two-fold 26's, and containing not fewer than 44 folded turns per inch, and are woven two ends right twist and two ends reverse twist. The weft of the fabric has not fewer than 20 threads per inch when the bandage is fully stretched, and the threads are of cotton yarn of a count not finer than 8·5's.

LIGAMENTUM LANULÆ

(Ligament. Lanul.)

Flannel Bandage

Flannel bandage consists of a raised fabric of plain weave, made entirely of wool, in one continuous length and containing no joins.

Standard.—Flannel bandage is composed of yarns of a good uniform grade, and the material is clean and reasonably free from weaving defects. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Foreign matter, not more than 3 per cent. Weight of the bandage, not less than 900 grains per 2 inches by 6 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 26 in the warp and not less than 28 in the weft.

LIGAMENTUM LINÆ

(Ligament. Lin.)

Bleached Calico Bandage

Bleached calico bandage consists of bleached cotton cloth of plain weave, in one continuous length and containing no joins.

Standard.—Bleached calico bandage is composed of yarns of a good medium grade, and the material is well-bleached to a good white, clean and reasonably free from leaf and shell. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Foreign matter, not more than 1·5 per cent. Weight of the bandage, not less than 210 grains per 2 inches by 4 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 67 in the warp and not less than 58 in the weft.

LIGAMENTUM LINÆ CRUDÆ**(Ligament. Lin. Crud.)****Unbleached Calico Bandage**

Unbleached calico bandage consists of unbleached cotton cloth of plain weave, in one continuous length and containing no joins.

Standard.—Unbleached calico bandage is composed of yarns of a good medium grade, and the material is clean and reasonably free from leaf and shell. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Foreign matter, not more than 10 per cent. Weight of the bandage, not less than 250 grains per 2 inches by 4 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 65 in the warp and not less than 60 in the weft.

LIGAMENTUM PASTÆ ZINCI**(Ligament. Past. Zinc.)****Zinc Paste Bandage**

Zinc paste bandage consists of white, open-weave, cotton fabric, impregnated with a paste of the following composition:—Zinc oxide, 17 parts, glycerin, 17 parts (by weight), sterilised refined glue, 6·5 parts, acacia, 8·5 parts, benzoic acid, 0·5 part, distilled water, sufficient to produce 100 parts (by weight). The weight of paste used for a bandage measuring 4 inches by 7 yards is 4 ounces, and the weights for bandages of other widths and lengths are in proportion. The bandage should be wrapped in grease-proof paper and **packed** in a sealed container.

Standard.—The warp of the fabric is of cotton yarn of a count not finer than 40's and not heavier than 30's, and the threads, per inch, not less than 30 and not more than 35. The weft of the fabric is of cotton yarn of a count not finer than 26's and not heavier than 16's, and the threads, per inch, not less than 20 and not more than 25.

LIGAMENTUM SINDONIS**(Ligament. Sindon.)****Muslin Bandage**

Synonym—Bleached Muslin Bandage.

Muslin bandage consists of cotton cloth of plain weave, known in commerce as butter cloth material, in one continuous length and containing no joins.

Standard.—Muslin bandage is composed of yarns of a good medium, uniform grade, and the material is well-bleached to a good white, clean and reasonably free from leaf and shell. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Foreign matter, not more than 1·5 per cent. Weight of the bandage, not less than 190 grains per 2·5 inches by 6 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 48 in the warp and not less than 30 in the weft.

LIGAMENTUM TEXTUM APERTUM

(Ligament. Text. Apert.)

Open-Wove Bandage

Synonym—White Open-Wove Bandage.

Open-weave bandage consists of cotton cloth of plain weave, in one continuous length and containing no joins.

Standard.—Open-weave bandage is composed of yarns of a good medium, uniform grade, and the material is well-bleached to a good white, clean and reasonably free from leaf and shell. The edges are evenly cut, parallel with the warp threads, and are reasonably free from loose threads. Foreign matter, not more than 1·5 per cent. Weight of the bandage, not less than 200 grains per 2 inches by 4 yards, the weights of bandages of other widths and lengths being in proportion. Average number of threads per inch, not less than 43 in the warp and not less than 27 in the weft. Bleached count of the warp yarn, not finer than 40's and not heavier than 33's.

LINTEUM ABSORBENS

(Lint. Absorb.)

Absorbent Lint

Synonyms—Lint; Cotton Lint; Unmedicated Lint.

Absorbent lint is a cotton cloth of plain weave, from the warp yarns of which a nap has been raised. It absorbs water readily, but its absorbency may be reduced considerably by medication, the degree of absorbency of the product depending upon the nature of the medicament incorporated. It should be **packed** in sealed packets.

Standard.—Absorbent lint is reasonably free from weaving defects, well-raised, readily tearable in both directions, and bleached to a good white. The component yarns are reasonably free from slubs, snarls and other defects causing lumps in the cloth, and the raised side of the

STUPA PHENOLIS**(Stup. Phenol.)****Phenol Tow***Synonym*—Carbolised Tow.

Phenol tow is tow impregnated with phenol, and may be prepared by immersing tow in a sufficient quantity of a solution of phenol in alcohol, removing the material from the solution, and pressing sufficiently to produce a tow containing, when dried and freshly prepared, about 5 per cent. of phenol. This tow rapidly loses phenol even when stored under the most favourable conditions. It should be packed in sealed packets and **stored** in a cool place.

In making this preparation the alcohol may be replaced by industrial methylated spirit, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

TELA CARBASI ET GOSSYPH**(Tel. Carbas. et Gossyp.)****Gauze and Cotton Tissue***Synonym*—Absorbent Gauze Tissue.

Gauze and cotton tissue consists of a thick layer of absorbent cotton wool enclosed in tubular, absorbent gauze. The average pound measures 19 to 20 inches by 2.75 yards. The tubular form of the absorbent gauze may not be evident in weights of 2 ounces or under.

Standard.—The absorbent gauze complies with the standard for Carbasus Absorbens, with the exception of the weft, which has not fewer than 12 threads per inch. The absorbent cotton wool complies with the standard for Gossypium Absorbens. Superficial area, not less than 1800 square inches per pound.

TELA CARBASI ET GOSSYPH CAPSICI**(Tel. Carbas. et Gossyp. Capsic.)****Capsicum Tissue**

Capsicum tissue consists of a thick layer of capsicum wool enclosed in tubular, absorbent gauze which has been tinted orange-brown with a suitable dye. The tubular form of the absorbent gauze may not be evident in weights of 2 ounces or under. It should be **packed** in sealed packets, doubly wrapped.

Standard.—The absorbent gauze complies with the standard for Carbasus Absorbens, with the exception of the colour and the weft, which has not fewer than 12 threads per inch. Superficial area, not less than 1800 square inches per pound.

TELA CARBASI ET LIGNI

(Tel. Carbas. et Lig.)

Cellulose Tissue

Synonym—Gauze and Cellulose Wadding Tissue.

Cellulose tissue consists of a thick layer of cellulose wadding enclosed in tubular absorbent gauze. The tubular form of the absorbent gauze may not be evident in weights of 2 ounces or under.

Standard.—The absorbent gauze complies with the standard for Carbasus Absorbens, with the exception of the weft, which has not fewer than 12 threads per inch. The cellulose wadding complies with the standard for Cellulosum Ligni. Superficial area, not less than 1350 square inches per pound.

TELA GUTTA PERCHA

(Tel. Gutt. Perch.)

Gutta Percha Tissue

Gutta percha tissue is gutta percha in thin sheets. It should be **stored** in a cool place.

Standard.—Gutta percha tissue has a superficial area of not less than 648 and not more than 730 square inches per ounce.

PART III
FORMULARY

The British Pharmaceutical Codex

PART III

ACETUM CANTHARIDINI

(Acet. Cantharidin.)

Vinegar of Cantharidin

	<i>Metric</i>	<i>Imperial</i>
Cantharidin	1 g.	4 $\frac{3}{8}$ gr.
Glacial Acetic Acid	200 ml.	2 fl. oz.
Acetic Acid	to 2000 ml.	to 20 fl. oz.

Dissolve the cantharidin in the glacial acetic acid with the aid of gentle heat; cool and add sufficient acetic acid to produce the required volume.

ACETUM CANTHARIDIS

(Acet. Canthar.)

Vinegar of Cantharides

	<i>Metric</i>	<i>Imperial</i>
Cantharides	100 g.	2 oz.
Glacial Acetic Acid	a sufficient quantity	
Distilled Water	a sufficient quantity	

Bruise the cantharides and macerate with 900 millilitres (18 fluid ounces) of a mixture of equal volumes of glacial acetic acid and distilled water for twenty-four hours; transfer to a percolator and, when the liquid ceases to pass, pour sufficient of the same menstruum in successive portions over the contents of the percolator to produce 1000 millilitres (20 fluid ounces).

ACETUM IPECACUANHÆ

(Acet. Ipecac.)

Vinegar of Ipecacuanha

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Ipecacuanha ..	50 ml.	1 fl. oz.
Alcohol (90 per cent.)	100 ml.	2 fl. oz.
Dilute Acetic Acid	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix, allow to stand for forty-eight hours and filter.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

ACETUM ODORATUM

(Acet. Odorat.)

Toilet Vinegar

			<i>Metric</i>	<i>Imperial</i>
Oil of Bergamot	5 ml.	48 m.
Oil of Cassia	1 ml.	10 m.
Oil of Clove	3 ml.	29 m.
Oil of Lavender	2 ml.	19 m.
Oil of Lemon	5 ml.	48 m.
Tincture of Tolu	10 ml.	96 m.
Tincture of Benzoin	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	500 ml.	10 fl. oz.
Acetic Acid	125 ml.	2½ fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the oils, tincture of tolu and tincture of benzoin with the alcohol; add the acetic acid and sufficient distilled water to produce the required volume; shake well, and filter, using purified talc if necessary.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, and the tincture of tolu and tincture of benzoin may be replaced by tinctures of tolu and benzoin prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

Toilet vinegar should be distinguished from aromatic vinegar (see Acidum Aceticum Aromaticum).

ACIDUM ACETICUM AROMATICUM

(Acid. Acet. Aromat.)

Aromatic Acetic Acid*Synonym*—Aromatic Vinegar.

			<i>Metric</i>	<i>Imperial</i>
Oil of Bergamot	25.0 ml.	½ fl. oz.
Oil of Cinnamon	12.5 ml.	¼ fl. oz.
Oil of Clove	100.0 ml.	2 fl. oz.
Oil of Lavender	50.0 ml.	1 fl. oz.
Oil of Orange	50.0 ml.	1 fl. oz.
Oil of Thyme	25.0 ml.	½ fl. oz.
Glacial Acetic Acid	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oils in about 700 millilitres (14 fluid ounces) of the glacial acetic acid and add sufficient of the acid to produce the required volume.

Aromatic vinegar should be distinguished from toilet vinegar (see Acetum Odoratum).

ACIDUM LACTICUM DILUTUM

(Acid. Lact. Dil.)

Dilute Lactic Acid

				<i>Metric</i>	<i>Imperial</i>
Lactic Acid	174.5 g.	2 oz. 346½ gr.
Distilled Water	825.5 g.	13 oz. 91 gr.

Mix.

Standard.—Dilute lactic acid, determined by the method of the British Pharmacopœia for Acidum Lacticum, using about 15 grammes accurately weighed, contains the equivalent of not less than 14.5 per cent. and not more than 17.0 per cent. w/w of $C_3H_5O_3$. It complies with the tests for purity of the British Pharmacopœia for Acidum Lacticum when six times the quantity is taken for each test. Specific gravity, about 1.04.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ACIDUM NITRICUM DILUTUM

(Acid. Nit. Dil.)

Dilute Nitric Acid

				<i>Metric</i>	<i>Imperial</i>
Nitric Acid	143 g.	2 oz. 126 gr.
Distilled Water	857 g.	13 oz. 311½ gr.

Mix.

Standard.—Dilute nitric acid, determined by the method of the British Pharmacopœia for Acidum Nitricum, using about 15 grammes accurately weighed, contains not less than 9.5 per cent. and not more than 10.5 per cent. w/w of HNO_3 . It complies with the tests for purity of the British Pharmacopœia for Acidum Nitricum when seven times the quantity is taken for each test. Specific gravity, 1.054 to 1.060.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

ACIDUM NITRO-HYDROCHLORICUM DILUTUM

(Acid. Nitro-hydrochlor. Dil.)

Dilute Nitro-hydrochloric Acid

				<i>Metric</i>	<i>Imperial</i>
Nitric Acid	126 g.	2 oz. 7 gr.
Hydrochloric Acid	137 g.	2 oz. 84 gr.
Distilled Water	737 g.	11 oz. 346½ gr.

Mix.

Standard.—Dilute nitro-hydrochloric acid contains nitric and hydrochloric acids and various reaction products of the constituent

acids equivalent to about 12·5 per cent. w/w of nitric acid and about 13·5 per cent. w/w of hydrochloric acid. 10 millilitres requires for neutralisation not less than 25·5 millilitres and not more than 29·0 millilitres of N/1 sodium hydroxide using methyl orange as indicator. Specific gravity, about 1·07.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

ACIDUM SULPHURICUM AROMATICUM

(Acid. Sulph. Aromat.)

Aromatic Sulphuric Acid

Synonym—Elixir of Vitriol.

	<i>Metric</i>	<i>Imperial</i>
Tincture of Ginger	250 ml.	5 fl. oz.
Spirit of Cinnamon	15 ml.	144 m.
Sulphuric Acid	70 ml.	1 fl. oz. 192 m.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the sulphuric acid gradually with 600 millilitres (12 fluid ounces) of the alcohol, and cool; add the spirit of cinnamon, tincture of ginger and sufficient of the alcohol to produce the required volume.

Standard.—Aromatic sulphuric acid contains free and combined sulphuric acid equivalent to not less than 12·2 per cent. and not more than 13·5 per cent. w/v of H_2SO_4 . Specific gravity, about 0·920.

Assay.—To 10 millilitres add 50 millilitres of N/1 sodium hydroxide and evaporate the mixture to dryness; dissolve the residue in water and titrate the solution with N/1 sulphuric acid using methyl orange as indicator; each millilitre of N/1 sodium hydroxide absorbed is equivalent to 0·04904 gramme of H_2SO_4 .

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

ALCOHOL AMMONIATUM

(Alcoh. Ammon.)

Ammoniated Alcohol

Alcohol (90 per cent.)	a sufficient quantity
Strong Solution of Ammonia	a sufficient quantity

Warm the strong solution of ammonia and pass the gas evolved into the alcohol. Determine the proportion of ammonia in the liquid and add, if necessary, sufficient of the alcohol to produce a solution of the required strength.

Standard.—Ammoniated alcohol, determined by the method of the British Pharmacopœia for Liquor Ammonizæ Fortis, using about 6

grammes, accurately weighed, contains not less than 9 per cent. and not more than 11 per cent. w/w of NH_3 . Specific gravity, about 0.815.

AMPULLÆ

Ampoules

Ampoules are glass containers for solutions or suspensions which are usually intended for injection through the skin. They vary in shape, and their capacities range from 0.5 millilitre (8 minims) to 100 millilitres ($3\frac{1}{2}$ fluid ounces). Most frequently they are of a capacity of 1 millilitre (15 minims). Ampoules should be made from glass of high chemical resistance and, when required to contain preparations of alkaloids or other substances such as adrenaline which are readily affected by alkali, they must not change the colour of acid solution of methyl red more than is permitted by the tests for limit of alkalinity of glass described in the British Pharmacopœia. When required for preparations liable to be affected by light, amber-coloured glass should be used. All apparatus used in the preparation of substances to be filled into ampoules, as well as the empty ampoules, should be sterilised by heating at 150° for one hour, or by an equivalent process.

Small numbers of ampoules may be filled conveniently with a hypodermic syringe, or a burette to which is attached a fine, hollow, glass or metal needle; the filled ampoules are sealed in a blow-pipe or bunsen flame. When filled, the ampoules should be sterilised by one of the methods described in Appendix XII. It is advisable to store filled ampoules in the dark at a temperature below 10° . Certain volatile liquids may be introduced into thin-walled ampoules by heating the ampoule, immersing the single drawn out end in the liquid, and allowing the liquid to fill the partial vacuum formed on cooling. Another type of ampoule is made from specially thin-walled tubing and is intended to be crushed and the contents inhaled. Ampoules may also be used as containers for definite quantities of solid substances, such as neoarsphenamine, sodium citrate, sodium bicarbonate or iodophthalein, required for the preparation of sterile solutions. Such solutions should be made by dissolving the substance in sterilised water, and are for immediate use.

AMYLUM SALICYLATUM

(Amylum Salicylat.)

Salicylated Starch

	<i>Metric</i>	<i>Imperial</i>
Salicylic Acid, finely sifted ..	100 g.	1 oz.
Starch, finely sifted ..	900 g.	9 oz.

Mix.

ANTIDOTUM ARSENUM

(Antidot. Arsen.)

Arsenic Antidote

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ferric Chloride	30 ml.	288 m.
Light Magnesium Oxide	10 g.	87½ gr.
Distilled Water	a sufficient quantity	

Mix the strong solution of ferric chloride with 125 millilitres (2½ fluid ounces) of the water, and keep the liquid in a well-stoppered bottle. Triturate the light magnesium oxide with distilled water to form a smooth and thin mixture, dilute this with sufficient distilled water to produce 750 millilitres (15 fluid ounces), and transfer the liquid to a well-stoppered bottle. When the preparation is required for use, shake the magnesium oxide mixture to a homogeneous thin magma and add 112.5 millilitres (3¾ fluid ounces) gradually in a thin stream to 25 millilitres (400 minims) of the iron solution, shaking until a smooth mixture results.

Dose.— 120 millilitres (4 fluid ounces).

AQUÆ**Waters**

Unmedicated water of three grades of purity is used in pharmacy—good potable water, distilled water and sterilised distilled water. Potable water may be used in the manufacture of official preparations when distilled water is not specified, but it is unsuitable as a general vehicle in dispensing on account of the presence of dissolved calcium and magnesium salts. These impart an alkaline reaction to the water and produce undesirable changes in the colour of certain vegetable galenicals; they also yield precipitates with many salts.

In the preparation of solutions to be administered by injection, it is necessary to use sterilised water (*Aqua Sterilisata*) owing to the bacterial contamination of ordinary distilled water. Intravenous injections should be prepared with “sterilised water for intravenous injections” which is not more than twenty-four hours old; for other purposes sterilised water should be used within a month of its distillation.

Aromatic waters are saturated solutions of volatile oils or other aromatic substances in distilled water. Some of them have a mild therapeutic action, but they are mainly used as vehicles for the internal administration of medicaments on account of their flavouring properties. The following general methods are employed in the preparation of aromatic waters when no specific method is described:—

1. Distilled Aromatic Waters.

Distil the drug with the water until the specified volume of distillate

has been collected, shake the distillate thoroughly, allow to stand for twelve hours and separate any excess of oil.

2. Other Aromatic Waters.

(a) Shake the essential oil with five hundred times its volume of distilled water and repeat the shaking at intervals during about fifteen minutes; set aside for twelve hours and filter.

(b) Triturate the oil with a sufficient quantity of calcium phosphate, purified talc, diatomite or pulped filter paper; add gradually five hundred times its volume of distilled water and filter.

(c) Add to the concentrated water thirty-nine times its volume of distilled water and filter if necessary.

AQUA ANISI CONCENTRATA

(Aq. Anis. Conc.)

Concentrated Anise Water

		<i>Metric</i>	<i>Imperial</i>
Oil of Anise	20 ml.	192 m.
Alcohol (90 per cent.)	600 ml.	12 fl. oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve the oil of anise in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to distilled anise water, but contains 1.5 per cent. v/v of alcohol (90 per cent.).

AQUA ANISI DESTILLATA

(Aq. Anis. Dest.)

Distilled Anise Water

		<i>Metric</i>	<i>Imperial</i>
Anise	100 g.	2 oz.
Water	2000 ml.	40 fl. oz.

Distil 1000 millilitres (20 fluid ounces).

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

When anise water (Aqua Anisi) is ordered, distilled anise water not being specified, anise water prepared by any one of the general methods may be dispensed.

AQUA AURANTII FLORIS

(Aq. Aurant. Flor.)

Orange-flower Water

	<i>Metric</i>	<i>Imperial</i>
Triple Orange-flower Water ..	250 ml.	5 fl. oz.
• Distilled Water	500 ml.	10 fl. oz.

Mix immediately before use.

When orange-flower water (Aqua Aurantii Floris) is ordered, either the above preparation or the concentrated water diluted with 39 times its volume of distilled water may be dispensed.

AQUA AURANTII FLORIS CONCENTRATA

(Aq. Aurant. Flor. Conc.)

Concentrated Orange-flower Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Neroli	6 ml.	57½ m.
Alcohol (90 per cent.) ..	600 ml.	12 fl. oz.
Triple Orange-flower Water ..	to 1000 ml.	to 20 fl. oz.

Dissolve the oil of neroli in the alcohol and add sufficient triple orange-flower water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to orange-flower water, but contains 1·5 per cent. v/v of alcohol (90 per cent.).

AQUA AURANTII FLORIS TRIPLEX

(Aq. Aurant. Flor. Trip.)

Triple Orange-flower Water

Triple orange-flower water is the undiluted orange-flower water of commerce prepared by distillation from the fresh flowers of the bitter-orange tree, *Citrus Aurantium* Linn. subsp. *amara* Engl. (Fam. Rutaceæ). It is a saturated aqueous solution of the volatile oil.

AQUA CAMPHORÆ CONCENTRATA

(Aq. Camph. Conc.)

Concentrated Camphor Water

	<i>Metric</i>	<i>Imperial</i>
Camphor	40 g.	350 gr.
Alcohol (90 per cent.) ..	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the camphor in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition.

Dose.— 0.3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is equivalent in strength to camphor water, but contains 1.5 per cent. v/v of alcohol (90 per cent.).

AQUA CARI CONCENTRATA

(Aq. Cari Conc.)

Concentrated Caraway Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Caraway	20 ml.	192 m.
Alcohol (90 per cent.)	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the oil of caraway in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.— 0.3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to distilled caraway water, but contains 1.5 per cent. v/v of alcohol (90 per cent.).

AQUA CARI DESTILLATA

(Aq. Cari Dest.)

Distilled Caraway Water

	<i>Metric</i>	<i>Imperial</i>
Caraway	100 g.	2 oz.
Water	2000 ml.	40 fl. oz.

Distil 1000 millilitres (20 fluid ounces).

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

When caraway water (Aqua Cari or Aqua Carui) is ordered, distilled caraway water not being specified, caraway water prepared by any one of the general methods may be dispensed.

AQUA CARYOPHYLLI CONCENTRATA

(Aq. Caryoph. Conc.)

Concentrated Clove Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Clove	20 ml.	192 m.
Alcohol (90 per cent.)	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the oil of clove in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to distilled clove water, but contains 1·5 per cent. v/v of alcohol (90 per cent.).

AQUA CARYOPHYLLI DESTILLATA

(Aq. Caryoph. Dest.)

Distilled Clove Water

	<i>Metric</i>	<i>Imperial</i>
Clove	25 g.	$\frac{1}{2}$ oz.
Water	2000 ml.	40 fl. oz.

Distil 1000 millilitres (20 fluid ounces) and filter when cold.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

When clove water (Aqua Caryophylli) is ordered, distilled clove water not being specified, clove water prepared by any one of the general methods may be dispensed.

AQUA CHLOROFORMI CONCENTRATA

(Aq. Chlorof. Conc.)

Concentrated Chloroform Water

	<i>Metric</i>	<i>Imperial</i>
Chloroform	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the chloroform in the alcohol and add gradually, with constant shaking, sufficient distilled water to produce the required volume.

Dose.— 0·4 to 0·8 millilitre (6 to 12 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is equivalent in strength to chloroform water, but contains 1·5 per cent. v/v of alcohol (90 per cent.).

AQUA CHLOROFORMI DUPLEX

(Aq. Chlorof. Dup.)

Double Chloroform Water*Synonyms*—Aqua Chloroformi Fortior; Stronger Chloroform Water.

	<i>Metric</i>	<i>Imperial</i>
Chloroform	5 ml.	48 m.
Distilled Water .. .	to 1000 ml.	to 20 fl. oz.

Shake frequently until solution is effected

Dose.— 8 to 16 millilitres (2 to 4 fluid drachms).**AQUA FÆNICULI CONCENTRATA**

(Aq. Fœnic. Conc.)

Concentrated Fennel Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Fennel	20 ml.	192 m.
Alcohol (90 per cent.) .. .	600 ml.	12 fl. oz
Distilled Water .. .	to 1000 ml.	to 20 fl. oz

Dissolve the oil of fennel in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to distilled fennel water, but contains 1·5 per cent. v/v of alcohol (90 per cent.).

AQUA FÆNICULI DESTILLATA

(Aq. Fœnic. Dest.)

Distilled Fennel Water

	<i>Metric</i>	<i>Imperial</i>
Fennel	100 g.	2 oz.
Water	2000 ml.	40 fl. oz.

Distil 1000 millilitres (20 fluid ounces).

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

When fennel water (Aqua Fœniculi) is ordered, distilled fennel water not being specified, fennel water prepared by any one of the general methods may be dispensed.

AQUA LAUROCERASI

(Aq. Laurocer.)

Cherry-laurel Water*Synonym*—Aqua laurocerasi I.A.

	<i>Metric</i>	<i>Imperial</i>
Cherry-laurel Leaf	1000 g.	20 oz.
Water	2000 ml.	40 fl. oz.

Dissolve 100 grammes (2 ounces) of sodium chloride in the water, add the crushed leaves and distil 1000 millilitres (20 fluid ounces). Shake the distillate, and filter if necessary. Determine the proportion of hydrocyanic acid in the product and adjust it by adding either hydrocyanic acid or distilled water to produce a cherry-laurel water of the required strength.

Standard.—Cherry-laurel water, determined by the method of the British Pharmacopœia for Acidum Hydrocyanicum Dilutum, contains not less than 0·09 per cent. and not more than 0·11 per cent. w/v of HCN.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

AQUA MELLIS

(Aq. Mel.)

Honey Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Bergamot .. .	7·8 ml.	75 m.
Oil of Lavender .. .	2·6 ml.	25 m.
Oil of Clove .. .	2·6 ml.	25 m.
Oil of Sandal Wood .	0·5 ml.	5 m.
Grain Musk .. .	0·75 g.	6 $\frac{1}{2}$ gr.
Saffron .. .	0·38 g.	3 $\frac{1}{2}$ gr.
Triple Rose Water .. .	150·0 ml.	3 fl. oz.
Triple Orange-flower Water .. .	150·0 ml.	3 fl. oz.
Purified Honey .. .	5·0 g.	43 $\frac{3}{4}$ gr.
Alcohol (90 per cent.) .. .	to 1000·0 ml.	to 20 fl. oz.

Dissolve the oils of bergamot, lavender, clove and sandal wood in 650 millilitres (13 fluid ounces) of the alcohol, add the grain musk and saffron, the honey mixed with the rose and orange-flower waters, and sufficient of the alcohol to produce the required volume. Set aside for seven days and filter, using purified talc or kaolin if necessary.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the final product contains 1 per cent. v/v of ethyl phthalate and that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

AQUA MENTHÆ VIRIDIS CONCENTRATA**(Aq. Menth. Vir. Conc.)****Concentrated Spearmint Water**

		<i>Metric</i>	<i>Imperial</i>
Oil of Spearmint	20 ml.	192 m.
Alcohol (90 per cent.)	600 ml.	12 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the oil of spearmint in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.— 0.3 to 1 millilitre (5 to 15 minims).

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to distilled spearmint water, but contains 1.5 per cent. v/v of alcohol (90 per cent.).

AQUA MENTHÆ VIRIDIS DESTILLATA**(Aq. Menth. Vir. Dest.)****Distilled Spearmint Water**

		<i>Metric</i>	<i>Imperial</i>
Oil of Spearmint	1 ml.	10 m.
Water	1500 ml.	30 fl. oz.

Distil 1000 millilitres (20 fluid ounces).

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

When spearmint water (Aqua Menthæ Viridis) is ordered, distilled spearmint water not being specified, spearmint water prepared by any one of the general methods may be dispensed.

AQUA MENTHOLIS**(Aq. Menthol.)****Menthol Water**

		<i>Metric</i>	<i>Imperial</i>
Menthol	1.1 g.	10 gr.
Alcohol (90 per cent.)	1.7 ml.	15 m.
Distilled Water	1000.0 ml.	20 fl. oz.

Dissolve the menthol in the alcohol, add the solution to the water, shake well, and filter after twenty-four hours.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

AQUA PIMENTÆ CONCENTRATA

(Aq. Piment. Conc.)

Concentrated Pimento Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Pimento	20 ml.	192 m.
Alcohol (90 per cent.)	600 ml.	12 fl. oz
Distilled Water	to 1000 ml.	to 20 fl. oz

Dissolve the oil of pimento in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

Dose.—0·3 to 1 millilitre (5 to 15 minims).

When pimento water (Aqua Pimentæ) is ordered, this preparation diluted with 39 times its volume of distilled water may be dispensed.

AQUA ROSÆ

(Aq. Ros.)

Rose Water

	<i>Metric</i>	<i>Imperial</i>
Triple Rose Water	250 ml.	5 fl. oz.
Distilled Water	500 ml.	10 fl. oz.

Mix immediately before use.

When rose water (Aqua Rosæ) is ordered, either the above preparation or the concentrated water diluted with 39 times its volume of distilled water, may be dispensed.

AQUA ROSÆ CONCENTRATA

(Aq. Ros. Conc.)

Concentrated Rose Water

	<i>Metric</i>	<i>Imperial</i>
Oil of Rose	10 ml.	96 m.
Alcohol (90 per cent.)	500 ml.	10 fl. oz
Distilled Water	to 1000 ml.	to 20 fl. oz

Dissolve the oil of rose in the alcohol and add sufficient distilled water in successive small quantities to produce the required volume, shaking vigorously after each addition. Add 50 grammes (1 ounce) of purified talc and shake; allow to stand for a few hours, occasionally shaking, and filter.

This concentrated water when diluted with 39 times its volume of distilled water yields a preparation which is approximately equivalent in strength to rose water, but contains 1·25 per cent. of alcohol (90 per cent.).

AQUA ROSÆ TRIPLEX

(Aq. Ros. Trip.)

Triple Rose Water

Triple rose water is the undiluted rose water of commerce, prepared by distillation from the fresh flowers of *Rosa damascena* Linn. (Fam. Rosaceæ). It is a saturated aqueous solution of the volatile oil.

AQUA SAMBUCI

(Aq. Sambuc.)

Elder-flower Water

	<i>Metric</i>	<i>Imperial</i>
Triple Elder-flower Water ..	250 ml.	5 fl. oz.
Distilled Water	500 ml.	10 fl. oz.

Mix immediately before use.

AQUA SAMBUCI TRIPLEX

(Aq. Sambuc. Trip.)

Triple Elder-flower Water

Triple elder-flower water is the undiluted elder-flower water of commerce, prepared by distillation from the fresh flowers of *Sambucus nigra* Linn. (Fam. Caprifoliacæ). It is a saturated aqueous solution of the volatile oil.

ARGENTI NITRAS MITIGATUS

(Argent. Nit. Mitig.)

Mitigated Silver Nitrate

Synonyms—Mitigated Caustic; Argenti Nitræ Dilutus.

	<i>Metric</i>	<i>Imperial</i>
Silver Nitrate	20 g.	1 oz.
Potassium Nitrate	40 g.	2 oz.

Fuse together, mix, and pour into suitable moulds.

It should be **stored** protected from light.

Standard.—Mitigated silver nitrate, determined by the method of the British Pharmacopœia for Argenti Nitræ Induratus, using about 1·5 grammes accurately weighed, contains not less than 32 per cent. and not more than 34 per cent. of AgNO_3 .

BALNEA**Baths**

The quantity of water used for a full-sized bath is usually 30 gallons. The temperature at which medicinal baths are given is from 35° to 40°, unless otherwise stated. For a cold bath (*Balneum Frigidum*), the patient is placed in water at 35° and the temperature of the water is lowered to 15° by the addition of ice. A tepid bath (*Balneum Tepidum*) is given at from 30° to 35°, and a hot bath (*Balneum Calidum*) at from 37° to 43°. Effervescing baths are given at a slightly lower temperature than ordinary baths, the effervescence giving to the patient an increased sense of warmth.

Medicated baths are prepared with the following quantities of medicaments in 140 litres (30 gallons) of water:—

Balneum Acidum.—Dilute nitro-hydrochloric acid, 440 millilitres (15 fluid ounces).

Balneum Alkalinum.—Sodium carbonate, 150 grammes (5 ounces).

Balneum Furfuris.—Bran, 1850 grammes (4 pounds).

Balneum Iodi.—Strong solution of iodine, 120 millilitres (4 fluid ounces).

Balneum Magnesii Sulphatis.—Magnesium sulphate, 460 grammes (16 ounces).

Balneum Sinapis.—Bath mustard, 350 grammes (12 ounces).

Balneum Sodii Chloridi.—Sodium chloride, 3250 grammes (7 pounds).

Balneum Sulphuratum.—Sulphurated potash, 230 grammes (8 ounces).

Balneum Sulphuris.—Sodium acid sulphate and sodium thio-sulphate, of each, 150 grammes (5 ounces).

BALNEUM EFFERVESCENS

(Baln. Efferv.)

Effervescent Bath

		<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	460 g.	16 oz.
Sodium Acid Sulphate	230 g.	8 oz.
Water to	140 litres	to 30 gallons

Dissolve the sodium bicarbonate in the water and add the sodium acid sulphate.

BALNEUM EFFERVESCENS CUM CHLORIDO**(Baln. Efferv. c. Chlorid.)****Effervescent Bath with Chloride**

	<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	460 g.	16 oz.
Sodium Acid Sulphate . . .	230 g.	8 oz.
Sodium Chloride .. .	1400 g.	48 oz.
Calcium Chloride . . .	230 g.	8 oz.
Water to 140 litres		to 30 gallons

Dissolve the sodium bicarbonate and the chlorides in the water and add the sodium acid sulphate.

BOROGLYCERINUM**(Boroglycer.)****Boroglycerin**

	<i>Metric</i>	<i>Imperial</i>
Boric Acid, in powder	480 g.	7½ oz.
Glycerin	640 g.	10 oz.

Add 320 grammes (5 ounces) of the boric acid to the glycerin, heat to a temperature rising to, but not exceeding, 150° until the weight of the mixture is reduced to 850 grammes (13¼ ounces); then cool and mix with the remainder of the boric acid.

BUGINARIA**Bougies**

Bougies are medicated pencils, specially adapted for the application of medicinal substances to the urethra, the nostrils, or the ears. They are prepared in the same way as suppositories, but they differ in shape, resembling a pointed rod. The basis is either oil of theobroma, or gelato-glycerin which may be prepared by dissolving 32·5 grammes (3¼ ounces) of gelatin in a mixture of 40 millilitres (4 fluid ounces) of glycerin and 40 millilitres (4 fluid ounces) of distilled water, the solution being evaporated on a water-bath to 100 grammes (10 ounces). The medicament should be incorporated in the melted basis, as in the preparation of suppositories, and the mixture poured down a warm wire or glass rod into suitable moulds, or drawn up into a lubricated glass tube of suitable diameter, allowed to solidify, then pushed out with a glass rod, and cut to the correct length, one end being subsequently pointed.

Urethral Bougies may have either a gelato-glycerin or oil of theobroma basis and may be of any length up to 15 centimetres (6 inches). Usually they are 6·5 centimetres (2½ inches) or 13 centimetres (5 inches) long, and weigh 1 gramme (15 grains) or 2·5 grammes (40 grains) and

have about the diameter of a No. 8 or No. 9 catheter respectively. When the size is not specified, the smaller size should be supplied. The oil of theobroma may be replaced, if desired, by one of the following mixtures: (1) Oil of theobroma, 90 parts; wool fat, 10 parts. Melt together and stir until cold. (2) Oil of theobroma, 50 parts; hydrous wool fat, 25 parts; white beeswax, 25 parts. Melt together and stir until cold.

Nasal Bougies resemble urethral bougies in shape but are 3 inches in length, and weigh about 18 grains. They are usually made with a gelato-glycerin basis.

Aural Bougies are shaped like the other bougies but are about $\frac{1}{2}$ inch in length, and weigh about 6 grains. Unless otherwise ordered, they are made with a gelato-glycerin basis.

BUGINARIA COCAINÆ

(Bugin. Cocain.)

Cocaine Urethral Bougies

			<i>Metric</i>	<i>Imperial</i>
Cocaine	0.032 g.	$\frac{1}{2}$ gr.
Oil of Theobroma	sufficient to fill a	1 gramme
			(15 grain)	mould.

Triturate the cocaine with a small quantity of the melted oil of theobroma, then add the remainder and pour into a suitable mould.

CAPSULÆ

Capsules

Capsules are used for enclosing medicaments for internal use and are made with a gelatin base containing a varying amount of glycerin according to the degree of hardness required. It is unusual to put liquids in hard capsules. Perles are capsules prepared by means of suitable machinery. The following formula yields a mass for soft capsules which is suitable for ordinary use.

			<i>Metric</i>	<i>Imperial</i>
Gelatin	24 g.	3 oz. 367 $\frac{1}{2}$ gr.
Syrup	7 g.	1 oz. 52 $\frac{1}{2}$ gr.
Glycerin	18 g.	2 oz. 385 gr.
Mucilage of Acacia	6 g.	420 gr.
Distilled Water	to 100 g.	to 16 oz.

Mix the syrup, glycerin, mucilage of acacia and distilled water and soak the gelatin in the mixture; when the gelatin has become thoroughly softened, heat on a water-bath until dissolved. When a softer

capsule is required, the mucilage of acacia may be replaced by syrup, glycerin, or water, or by mixtures of these ingredients, according to the degree of hardness required. Soft capsules are obtainable in various sizes having capacities of 0.2, 0.3, 0.6, 0.9, 1.2, 1.8, 3.5 and 5.3 millilitres (3, 5, 10, 15, 20, 30, 60 and 90 minims).

Aqueous or alcoholic liquids tend to soften the capsule and such liquids should be concentrated and mixed with almond oil or liquid paraffin before being placed in the capsules. Liquid extracts are generally evaporated so that a 0.6 millilitre (10 minim) capsule represents 2 millilitres (30 minims) of the normal extract. Soft aqueous extracts or masses should similarly be incorporated with a little soft paraffin. Liquids such as creosote, guaiacol, oils of cinnamon and clove, etc., which may cause discomfort in the stomach if enclosed undiluted in capsules, should be mixed with four times their volume of almond or olive oil. Solids, such as quinine sulphate and ammonium bicarbonate, for administration in soft gelatin capsules should be powdered, and mixed separately with a basis of liquid and soft paraffins.

Hard or soft gelatin capsules containing such substances as pancreatin or extract of male fern, are required to pass through the stomach undissolved and to dissolve in the intestines. For this purpose they should, after filling and sealing, be immersed for five minutes in solution of formaldehyde diluted with three times its volume of water, and afterwards dried. Such capsules are known as glutoid capsules. The action of formaldehyde on the gelatin in the base varies with the time of immersion and the amount of gelatin in the base; the solubility of the finished capsules may be tested by treatment with suitable reagents. Capsules which dissolve in an aqueous solution of glycerin of pepsin and hydrochloric acid, when maintained in the reagent at 37° to 38° for two hours, will probably dissolve in the stomach, whereas capsules which dissolve within two hours at 37° to 38° in an aqueous solution of sodium bicarbonate containing pancreatin, may dissolve readily in the duodenum. Variation in the composition of the capsule-mass influences greatly the effect of the reagents and the strengths of the latter, therefore, require adjustment for different masses.

CAPSULÆ QUININÆ AMMONIATÆ

(Caps. Quinin. Ammon.)

Capsules of Ammoniated Quinine

		<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	0.065 g.	1 gr.
Ammonium Bicarbonate	0.162 g.	2½ gr.

Mix separately with a suitable paraffin basis and enclose in a capsule.

Dose.— 1 capsule.

CAPSULÆ QUININÆ AMMONIATÆ ET CINNAMOMI

(Caps. Quinin. Ammon. et Cinnam.)

Capsules of Ammoniated Quinine and Cinnamon

		<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	0.065 g.	1 gr.
Ammonium Bicarbonate..	0.162 g.	2½ gr.
Oil of Cinnamon	0.015 ml.	¼ m.

Mix separately with a suitable paraffin basis and enclose in a capsule.

Dose.— 1 capsule.

CAPSULÆ QUININÆ ET CINNAMOMI

(Caps. Quinin. et Cinnam.)

Capsules of Quinine and Cinnamon

		<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	0.065 g.	1 gr.
Oil of Cinnamon	0.059 ml.	1 m.

Mix separately with a suitable paraffin basis and enclose in a capsule.

Dose.— 1 capsule.

CAPSULÆ AMYLACÆ**Cachets**

Cachets are containers prepared from a mixture of flour and water, consisting of two circular discs adhering by their edges and are filled and closed by means of a suitable machine. They form one of the most useful methods of administering a solid medicament in tasteless form. Dry-closing cachets are also used and are recommended on account of the ease with which they may be filled and sealed. Cachets are obtainable in various sizes, the diameter of the smallest being somewhat larger than that of a 5 grain pill and the largest holding about 20 grains of a powder of medium density. When labelling cachets, in addition to the directions of the physician, instructions should be given as to the method of taking them. They should be immersed in water for a few seconds, then swallowed with the liquid.

Substances having a dosage of under 0.06 gramme (1 grain) should be triturated with lactose before being placed in the cachet. Hygroscopic substances should not be prescribed in cachets, but when so ordered it is advisable to mix them with powdered liquorice. Soft pill masses flattened into small discs and well covered with an inert absorbent powder may be dispensed in cachets. Bi-cachets should be used for substances which interact, the salts being placed separately in the halves of the cachet and separated by a single cachet disc of smaller diameter than the cachet which is being used.

CASEINUM GLYCEROPHOSPHATICUM**(Casein. Glycerophosph.)****Glycerophosphated Casein**

	<i>Metric</i>	<i>Imperial</i>
Soluble Casein	950 g.	15 oz. 87½ gr.
Sodium Glycerophosphate . .	25 g.	175 gr.
Calcium Glycerophosphate . .	25 g.	175 gr.

Powder the glycerophosphates and mix thoroughly with the soluble casein.

It should be **stored** in well-closed containers.

Dose.—4 to 16 grammes (1 to 4 drachms).

CATAPLASMATA**Poultices**

Poultices are thick, pasty preparations, usually intended to be made extemporaneously. They are frequently prepared with stale bread, crushed linseed or powdered slippery elm and, except in special cases, boiling water is placed in a previously warmed basin and the material stirred in with a spoon until a mass of the proper consistence results. The poultice is placed in a muslin bag and applied hot; it may be covered, if necessary, with jaconet, oiled silk, or gutta-percha tissue.

For medicated and other poultices, unless otherwise directed by the prescriber, the following proportions are suitable for use:—

Cataplasma Acidi Borici.—Boric acid, 20 per cent., in linseed poultice.

Cataplasma Acidi Borici et Carbonis.—Boric acid and charcoal, of each 4 per cent., in slippery elm poultice.

Cataplasma Amyli.—Starch, 10 per cent., boiled with water.

Cataplasma Amyli et Acidi Borici.—Boric acid, 6 per cent., in starch poultice.

Cataplasma Carbonis.—Charcoal, 10 per cent., in linseed poultice.

Cataplasma Iodi.—Weak solution of iodine, 2 fluid drachms, in linseed poultice.

Cataplasma Phenolis.—Phenol, 2 per cent., in linseed poultice.

Cataplasma Sinapis.—Mustard flour, 2 per cent., in linseed poultice.

Cataplasma Sodæ Chlorinatæ.—Linseed poultice prepared with a mixture of equal volumes of solution of chlorinated soda and water.

CERA ASEPTICA

(Cera Asep.)

Aseptic Wax

			<i>Metric</i>	<i>Imperial</i>
White Beeswax	875 g.	14 oz.
Almond Oil	125 ml.	2 fl. oz.
Salicylic Acid	10 g.	70 gr.

Melt the beeswax with the oil and strain through muslin, add the salicylic acid and heat for thirty minutes on a water-bath.

It should be **stored** in sterilised bottles, covered with an aqueous solution (1 in 500) of mercuric chloride.

CHARTA NITRATA

(Charta Nit.)

Nitrated Paper

Synonyms—Saltpetre Paper; Nitre Paper.

Nitrated paper is prepared by saturating white blotting paper with a 20 per cent. w/v aqueous solution of potassium nitrate, and drying.

CHLORAL CAMPHORATUM

(Chloral Camph.)

Camphorated Chloral

Synonym—Chloral cum Camphora.

			<i>Metric</i>	<i>Imperial</i>
Camphor	500 g.	8 oz.
Chloral Hydrate	500 g.	8 oz.

Rub together in a warm mortar until completely liquefied, and strain if necessary. The product measures about 875 millilitres (14 fluid ounces).

CHLOROFORMUM ACONITI

(Chlorof. Aconit.)

Chloroform of Aconite

			<i>Metric</i>	<i>Imperial</i>
Aconite, in moderately fine powder			1000 g.	20 oz.
Dilute Solution of Ammonia	..		250 ml.	5 fl. oz.
Alcohol (90 per cent.)	a sufficient	quantity
Chloroform	a sufficient	quantity

Moisten the aconite with the dilute solution of ammonia and set aside for twenty-four hours. Transfer to a percolator, and percolate with a menstruum consisting of one volume of alcohol and seven volumes of chloroform until 1000 millilitres (20 fluid ounces) of percolate is obtained.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

CHLOROFORMUM ATROPINÆ

(Chlorof. Atrop.)

Chloroform of Atropine

	<i>Metric</i>	<i>Imperial</i>
Atropine	4.6 g.	40 gr.
Alkanna, coarsely powdered ..	2.3 g.	20 gr.
Chloroform to 1000.0 ml.	to 20 fl. oz.

Macerate the alkanna in 900 millilitres (18 fluid ounces) of chloroform for forty-eight hours, filter, dissolve the atropine in the liquid, and add sufficient chloroform to produce the required volume.

CHLOROFORMUM BELLADONNÆ

(Chlorof. Bellad.)

Chloroform of Belladonna

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Belladonna ..	500.0 ml.	10 fl. oz.
Heavy Magnesium Oxide ..	4.6 g.	40 gr.
Exsiccated Sodium Sulphate ..	300.0 g.	6 oz.
Alcohol (90 per cent.) ..	100.0 ml.	2 fl. oz.
Chloroform to 1000.0 ml.	to 20 fl. oz.

Place the liquid extract, magnesium oxide, alcohol and 750 millilitres (15 fluid ounces) of the chloroform in a dry bottle and shake well; add three-quarters of the exsiccated sodium sulphate, shake frequently during ten minutes and filter; to the filtrate add the remainder of the exsiccated sodium sulphate, agitate as before, filter, and add sufficient chloroform to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength and the liquid extract of belladonna may be replaced by liquid extract of belladonna prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

CHLOROFORMUM CAMPHORATUM

(Chlorof. Camph.)

Camphorated Chloroform*Synonym*—Chloroform of Camphor.

			<i>Metric</i>	<i>Imperial</i>
Camphor	600 g.	12 oz.
Chloroform	300 ml.	6 fl. oz.

Dissolve the camphor in the chloroform. The product measures about 900 millilitres (18 fluid ounces).

COLLODIUM ACETONUM

(Collod. Aceton.)

Acetone Collodion

			<i>Metric</i>	<i>Imperial</i>
Pyroxylin	50 g.	1 oz.
Oil of Clove	20 ml.	192 m.
Amyl Acetate	250 ml.	5 fl. oz.
Benzene	200 ml.	4 fl. oz.
Acetone	to 1000 ml.	to 20 fl. oz.

Dissolve the pyroxylin in 500 millilitres (10 fluid ounces) of the acetone, add the oil of clove, amyl acetate, benzene and sufficient acetone to produce the required volume.

COLLODIUM ANODYNUM

(Collod. Anodyn.)

Anodyne Collodion*Synonym*—Anodyne Colloid.

			<i>Metric</i>	<i>Imperial</i>
Aconitine	1·1 g.	10 gr.
Veratrine	6·9 g.	60 gr.
Acetone	300·0 ml.	6 fl. oz.
Acetone Collodion	to 1000·0 ml.	to 20 fl. oz.

Dissolve the aconitine and veratrine in the acetone and add sufficient acetone collodion to produce the required volume.

COLLODIUM ATROPINÆ

(Collod. Atrop.)

Atropine Collodion

	<i>Metric</i>	<i>Imperial</i>
Atropine	4.6 g.	40 gr.
Acetone	300.0 ml.	6 fl. oz.
Acetone Collodion to 1000.0 ml.		to 20 fl. oz.

Dissolve the atropine in the acetone and add sufficient acetone collodion to produce the required volume.

COLLODIUM BELLADONNÆ

(Collod. Bellad.)

Belladonna Collodion

Synonyms—Emplastrum Belladonnæ Fluidum; Liquid Belladonna Plaster.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Belladonna ..	500 ml.	10 fl. oz.
Canada Balsam	40 g.	350 gr.
Castor Oil	20 ml.	192 m.
Camphor	15 g.	131½ gr.
Pyroxylin	25 g.	½ oz.
Alcohol (90 per cent.)	100 ml.	2 fl. oz.
Ether to 1000 ml.		to 20 fl. oz.

Mix the liquid extract of belladonna, canada balsam, castor oil, alcohol and 400 millilitres (8 fluid ounces) of the ether, shake well and allow to stand for twelve hours; decant the clear liquid and strain the remainder, mix the two liquids, dissolve the camphor and pyroxylin in the mixture and add sufficient ether to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, and the liquid extract of belladonna may be replaced by liquid extract of belladonna prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

COLLODIUM CARBOLISATUM

(Collod. Carbol.)

Carbolised Collodion

	<i>Metric</i>	<i>Imperial</i>
Phenol	500 g.	8 oz.
Simple Collodion	500 g.	8 oz.

Melt the phenol and mix with the simple collodion so as to form a jelly.

COLLODIUM ICHTHAMMOLIS

(Colloid. Ichtham.)

Ichthammol Collodion*Synonym*—Ammonium Ichthosulphonate Collodion.

				<i>Metric</i>	<i>Imperial</i>
Ichthammol	125 g.	2½ oz.
Simple Collodion to 1000 ml.		to 20 fl. oz.

Dissolve the ichthammol in sufficient simple collodion to produce the required volume.

COLLODIUM ICHTHAMMOLIS CUM ÆTHERE

(Colloid. Ichtham. c. Æth.)

Ichthammol Collodion with Ether*Synonym*—Ammonium Ichthosulphonate Collodion with Ether.

				<i>Metric</i>	<i>Imperial</i>
Ichthammol	250 g.	5 oz.
Ether	250 ml.	5 fl. oz.
Simple Collodion to 1000 ml.		to 20 fl. oz.

Mix the ether with about 500 millilitres (10 fluid ounces) of simple collodion, dissolve the ichthammol in the mixture, and add sufficient simple collodion to produce the required volume.

COLLODIUM IODI

(Colloid. Iod.)

Iodine Collodion

				<i>Metric</i>	<i>Imperial</i>
Iodine	65 g.	1 oz. 13¼ gr.
Flexible Collodion to 1000 ml.		to 20 fl. oz.

Dissolve the iodine in sufficient flexible collodion to produce the required volume.

COLLODIUM SALICYLICUM

(Colloid. Salicyl.)

Salicylic Collodion

				<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	120 g.	2 oz. 175 gr.
Acetone	300 ml.	6 fl. oz.
Acetone Collodion to 1000 ml.		to 20 fl. oz.

Dissolve the salicylic acid in the acetone and add sufficient acetone collodion to produce the required volume.

COLLODIUM SALICYLICUM COMPOSITUM

(Collod. Salicyl. Co.)

Compound Salicylic Collodion*Synonym*—Collodium Callosum.

	<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	120 g.	2 oz. 175 gr.
Extract of Cannabis	20 g.	175 gr.
Acetone	300 ml.	6 fl. oz.
Acetone Collodion	to 1000 ml.	to 20 fl. oz.

Dissolve the salicylic acid and the extract of cannabis in the acetone and add sufficient acetone collodion to produce the required volume.

COLLODIUM SIMPLEX

(Collod. Simp.)

Simple Collodion

	<i>Metric</i>	<i>Imperial</i>
Pyroxylin	21 g.	183 $\frac{3}{4}$ gr.
Ether	750 ml.	15 fl. oz.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.

Immerse the pyroxylin in the alcohol, add the ether and shake occasionally until dissolved; set aside for a few days and decant if necessary.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

COLLODIUM STYPTICUM

(Collod. Stypt.)

Styptic Collodion

	<i>Metric</i>	<i>Imperial</i>
Benzoin, crushed	15 g.	131 $\frac{1}{4}$ gr.
Alcohol (90 per cent.)	150 ml.	3 fl. oz.
Tannic Acid	150 g.	3 oz.
Simple Collodion	to 1000 ml.	to 20 fl. oz.

Dissolve the benzoin and tannic acid in the alcohol and add sufficient simple collodion to produce the required volume; set aside for three days and decant the clear liquid.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

COLLODIUM VESICANS

(Colloid. Vesic.)

Blistering Collodion

	<i>Metric</i>	<i>Imperial</i>
Pyroxylin	25 g.	$\frac{1}{2}$ oz.
Cochineal, in powder	10 g.	$87\frac{1}{2}$ gr.
Blistering Liquid	to 1000 ml.	to 20 fl. oz.

Shake the cochineal with the pyroxylin and sufficient blistering liquid to produce the required volume until the pyroxylin is dissolved; set aside until clear and decant the clear liquid.

COLLYRIA**Eye Lotions**

Eye lotions are usually solutions in water of one or more substances. As far as possible they should be sterile, and they should be entirely free from foreign matter. In most cases, the final product should be filtered, preferably through a bacteria-proof filter. When complete sterilisation is not possible, the distilled water employed should be freshly boiled. The use of aromatic waters as vehicles should in general be discouraged; when they are prescribed the concentrated waters should be diluted immediately before use with freshly boiled and cooled distilled water. Eye lotions should be dispensed in sterile stoppered bottles of distinctive shape.

Isotonic Eye Lotions. To prepare an aqueous solution of any one of the following substances so that it is isotonic with the lachrymal secretion, the quantity given below should be dissolved in sufficient water to produce 100 millilitres (4 fluid ounces):—

Boric Acid	3.1 grammes	(54 $\frac{1}{4}$ grains)
Potassium Nitrate	2.4 grammes	(42 grains)
Sodium Bicarbonate	2.0 grammes	(35 grains)
Sodium Chloride	1.4 grammes	(24 $\frac{1}{2}$ grains)
Sodium Nitrate	2.0 grammes	(35 grains)

When an eye lotion is required to be rendered isotonic by the addition of another substance, the amount to be added, *W*, may be calculated approximately from the formula

$$W = \frac{0.86 - a}{b} \text{ per cent. w/v,}$$

where *a* denotes the freezing-point of the unadjusted lotion in degrees below 0° and *b* denotes the depression of the freezing-point of water produced by 1 per cent. w/v of the adjusting substance.

The value of *a* for any prescribed strength of a substance may be found by multiplying the strength expressed as a percentage w/v by

the value of *b* for the same substance. The values of *b* for a number of substances are given under Injections.

The following substances are used in eye lotions; when the proportions are not indicated by the prescriber, the following strengths should be dispensed:—

Collyrium Acidi Salicylici.—Salicylic acid, 0·1 per cent. w/v.

Collyrium Ammonii Chloridi.—Ammonium chloride, 0·5 per cent. w/v.

Collyrium Belladonnæ.—Green extract of belladonna, 0·5 per cent. w/v.

Collyrium Boracis.—Borax, 1 per cent. w/v.

Collyrium Cupri Sulphatis.—Copper sulphate, 0·25 per cent. w/v.

Collyrium Hydrargyri Perchloridi.—Mercuric chloride, 0·02 per cent. w/v.

Collyrium Picis Carbonis.—Solution of coal tar, 0·6 per cent. w/v.

Collyrium Quininae Hydrochloridi.—Quinine hydrochloride, 0·5 per cent. w/v.

Collyrium Sodii Bicarbonatis.—Sodium bicarbonate, 2 per cent. w/v.

Collyrium Zinci Chloridi.—Zinc chloride, 0·1 per cent. w/v.

Collyrium Zinci Sulphatis.—Zinc sulphate, 0·2 per cent. w/v.

COLLYRIUM ACIDI BORICI

(Collyr. Acid. Boric.)

Boric Acid Eye Lotion

	<i>Metric</i>	<i>Imperial</i>
Boric Acid	20 g.	175 gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.
Dissolve.		

COLLYRIUM ACIDI BORICI ET ZINCI

(Collyr. Acid. Boric. et Zinc.)

Boric Acid and Zinc Eye Lotion

	<i>Metric</i>	<i>Imperial</i>
Boric Acid	10 g.	87½ gr.
Zinc Sulphate	2 g.	17½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.
Dissolve.		

COLLYRIUM ALUMINIS

(Collyr. Alum.)

Alum Eye Lotion

	<i>Metric</i>	<i>Imperial</i>
Alum	10 g.	87½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve.

CONFECTIO GUAIACI COMPOSITA

(Conf. Guaiac. Co.)

Compound Confection of Guaiacum*Synonym*—Chelsea Pensioner.

	<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin, in powder ..	10 g.	70 gr.
Rhubarb, in powder	20 g.	140 gr.
Potassium Acid Tartrate ..	75 g.	1 oz. 87½ gr.
Nutmeg, in powder	10 g.	70 gr.
Sublimed Sulphur	145 g.	2 oz. 140 gr.
Purified Honey	740 g.	11 oz. 367½ gr.

Mix the guaiacum resin, rhubarb, potassium acid tartrate, nutmeg and sulphur and add gradually to the purified honey with constant trituration; mix thoroughly.

Dose.— 4 to 8 grammes (1 to 2 drachms).

CONFECTIO PIPERIS

(Conf. Piper.)

Confection of Pepper

	<i>Metric</i>	<i>Imperial</i>
Black Pepper, in powder ..	100 g.	1 oz. 262½ gr.
Caraway, in powder	150 g.	2 oz. 175 gr.
Purified Honey	750 g.	12 oz.

Mix.

Dose.— 4 to 8 grammes (1 to 2 drachms).

CONFECTIO ROSÆ CANINÆ

(Conf. Ros. Can.)

Confection of Rose Fruit*Synonym*—Confection of Hips.

Rose Fruit, deprived of its achenes	a sufficient quantity
Sucrose	a sufficient quantity

Beat the rose fruit in a stone mortar and rub the pulp thus produced through a sieve; add to the product twice its weight of sucrose and rub them well together.

CONFECTIO ROSÆ GALLICÆ

(Conf. Ros. Gall.)

Confection of Roses

	<i>Metric</i>	<i>Imperial</i>
Red-rose Petal, fresh	250 g.	4 oz.
Sucrose	750 g.	12 oz.

Beat together in a stone mortar.

CONFECTIO SENNÆ ET SULPHURIS

(Conf. Senn. et Sulphur.)

Confection of Senna and Sulphur

	<i>Metric</i>	<i>Imperial</i>
Confection of Senna	500 g.	8 oz.
Confection of Sulphur	500 g.	8 oz.

Mix thoroughly.

Dose.— 4 to 8 grammes (1 to 2 drachms).

CREMOR ZINCI

(Crem. Zinc.)

Zinc Cream

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide, finely sifted. . . .	320 g.	5 oz. 52½ gr.
Wool Fat	80 g.	1 oz. 122½ gr.
Almond Oil	320 ml.	5 fl. oz. 57½ m.
Solution of Calcium Hydroxide	to 1000 g.	to 16 oz.

Triturate the zinc oxide with the almond oil, incorporate the wool fat and sufficient solution of calcium hydroxide to produce the required weight.

CRETA CUM CAMPHORA

(Cret. c. Camph.)

Camphorated Chalk

	<i>Metric</i>	<i>Imperial</i>
Camphor	100 g.	1 oz.
Calcium Carbonate	900 g.	9 oz.

Dissolve the camphor in 50 millilitres ($\frac{1}{2}$ fluid ounce) of warm alcohol (90 per cent.), add the solution to 300 millilitres (3 fluid ounces) of water, collect the precipitated camphor, allow to drain, mix with the calcium carbonate and pass through a fine sieve.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

DECOCTA

Decoctions

A decoction is an aqueous preparation of a drug made by boiling the drug, either whole or suitably prepared, with distilled water for a specified time, straining and, if necessary, making up to the required volume with more distilled water. The method is applicable to drugs containing astringent matter and those of a hard resinous nature which do not readily yield their active principles to water. It is not suitable for drugs containing volatile or aromatic principles. When such drugs are ingredients of decoctions they are added towards the end of the period of boiling. Care should be taken in the choice of vessel for boiling. Glass, earthenware, enamelled-iron, or acid-resisting metal vessels are preferable, but aluminium, uncoated iron, copper, tin-ware and soldered vessels should be avoided. Decoctions are liable to undergo decomposition and should be freshly prepared. Concentrated decoctions, when suitably diluted, yield preparations of approximately the same composition as the ordinary decoctions.

In the absence of any specific instructions for making a decoction, 5 parts of drug should be boiled with 120 parts of distilled water for ten minutes, strained, and the volume adjusted, if necessary, to 100 parts by the addition of distilled water.

DECOCTUM AGROPYRI

(Dec. *Agropyri*.)

Decoction of Couch Grass

Synonym—Decoction of Triticum.

	<i>Metric</i>	<i>Imperial</i>
Couch Grass, cut small	50 g.	1 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the couch grass for ten minutes with 1200 millilitres (24 fluid ounces) of distilled water. Allow to cool, strain and, if necessary, pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.— 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

DECOCTUM ALOES COMPOSITUM

(Dec. Aloes Co.)

Compound Decoction of Aloes

	<i>Metric</i>	<i>Imperial</i>
Aloes	10 g.	87½ gr.
Myrrh .. .	5 g.	43½ gr.
Potassium Carbonate .. .	5 g.	43½ gr.
Extract of Liquorice .. .	40 g.	350 gr.
Compound Tincture of Cardamom	300 ml.	6 fl. oz.
Distilled Water .. . to	1000 ml.	20 fl. oz.

Reduce the aloes and the myrrh to coarse powder, add the potassium carbonate and the extract of liquorice, and boil with 400 millilitres (8 fluid ounces) of distilled water in a covered vessel for five minutes; cool, add the compound tincture of cardamom, set aside for two hours, strain through flannel and pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.— 15 to 60 millilitres (½ to 2 fluid ounces).

When compound decoction of aloes (Decoction Aloes Compositum) is prescribed, either the above preparation, or Decoction Aloes Compositum Concentratum diluted with three times its volume of distilled water, may be dispensed.

DECOCTUM ALOES COMPOSITUM CONCENTRATUM

(Dec. Aloes Co. Conc.)

Concentrated Compound Decoction of Aloes

	<i>Metric</i>	<i>Imperial</i>
Aloes	40.0 g.	350 gr.
Myrrh .. .	20.0 g.	175 gr.
Potassium Carbonate .. .	20.0 g.	175 gr.
Extract of Liquorice .. .	160.0 g.	3 oz. 87½ gr.
Cochineal, in powder .. .	12.0 g.	105 gr.
Cardamom, in powder .. .	15.0 g.	131½ gr.
Oil of Cinnamon .. .	0.3 ml.	3 m.
Oil of Caraway .. .	0.4 ml.	4 m.
Alcohol (90 per cent.) .. .	150.0 ml.	3 fl. oz.
Distilled Water .. . to	1000.0 ml.	20 fl. oz.

Reduce the aloes and the myrrh to coarse powder, add the potassium carbonate, extract of liquorice and cochineal; boil with 500 millilitres (10 fluid ounces) of distilled water until the extract and the aloes are dissolved, and filter; macerate the cardamom in the alcohol, filter, and

add the oils; mix the two liquids, add sufficient distilled water to produce the required volume and filter if necessary.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

This concentrated decoction when diluted with three times its volume of distilled water yields a preparation which is approximately equivalent in strength to compound decoction of aloes, but contains a smaller proportion of alcohol.

DECOCTUM CHONDRI

(Dec. Chond.)

Decoction of Chondrus

Synonyms—Decoction of Irish Moss; Mucilago Chondri;
Mucilage of Irish Moss.

	<i>Metric</i>	<i>Imperial</i>
Chondrus.	25 g.	$\frac{1}{2}$ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Wash the chondrus in cold water to remove impurities and boil with 1200 millilitres (24 fluid ounces) of distilled water for fifteen minutes. Strain while hot and, if necessary, pour sufficient distilled water over the contents of the strainer to produce the required volume.

It should be freshly prepared.

Dose.— 30 to 120 millilitres (1 to 4 fluid ounces), or more.

DECOCTUM CINCHONÆ CONCENTRATUM

(Dec. Cinchon. Conc.)

Concentrated Decoction of Cinchona

	<i>Metric</i>	<i>Imperial</i>
Cinchona, in moderately coarse powder	500 g.	10 oz.
Glycerin	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	100 ml.	2 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add the cinchona to 8000 millilitres (160 fluid ounces) of boiling distilled water and continue to boil for ten minutes in a covered vessel. Allow to cool, strain, and wash the contents of the strainer with distilled water. Evaporate the mixed decoction and washings to 650 millilitres (13 fluid ounces); allow to cool, filter, add the glycerin, the alcohol, and, if necessary, sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

When decoction of cinchona (Decoction Cinchonæ) is prescribed, this concentrated decoction diluted with seven times its volume of distilled water may be dispensed.

DECOCTUM GOSSYPI CORTICIS

(Dec. Gossyp. Cort.)

Decoction of Cotton Root Bark

	<i>Metric</i>	<i>Imperial</i>
Cotton Root Bark, bruised	200 g.	4 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the cotton root bark with 2000 millilitres (40 fluid ounces) of distilled water until the volume is reduced to 1000 millilitres (20 fluid ounces); strain, and pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.— 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

DECOCTUM HÆMATOXYLI

(Dec. Hæmatox.)

Decoction of Logwood

	<i>Metric</i>	<i>Imperial</i>
Logwood, in chips	50 g.	1 oz.
Cinnamon, bruised	10 g.	87½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the logwood with 1200 millilitres (24 fluid ounces) of distilled water for ten minutes, adding the cinnamon towards the end of the time; strain and, if necessary, pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.— 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

DECOCTUM HORDEI

(Dec. Hord.)

Decoction of Barley*Synonym*—Barley Water.

	<i>Metric</i>	<i>Imperial</i>
Pearl Barley, of commerce	100 g.	2 oz.
Distilled Water	1500 ml.	30 fl. oz.

Wash the pearl barley with cold water and reject the washings; boil the washed barley with the distilled water for twenty minutes in a covered vessel and strain. The product measures about 1000 millilitres (20 fluid ounces).

Dose.— 30 to 120 millilitres (1 to 4 fluid ounces).

DECOCTUM PAPAVERIS ET ANTHEMIDIS FORTE

(Dec. Papav. et Anthem. Fort.)

Strong Decoction of Poppy and Chamomile*Synonym*—Decoctum Papaveris et Anthemidis Concentratum.

	<i>Metric</i>	<i>Imperial</i>
Chamomile	250 g.	5 oz.
Poppy Capsule, bruised	250 g.	5 oz.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the chamomile and the poppy capsule for ten minutes with 6000 millilitres (120 fluid ounces) of distilled water. Pour off the liquid and evaporate it to 500 millilitres (10 fluid ounces); exhaust the chamomile and poppy capsule with a further quantity of water, decant the liquid, evaporate it to 250 millilitres (5 fluid ounces) and mix with the previously reserved liquid. Allow to cool and add the alcohol; allow to settle, decant the clear liquid, filter the remainder and mix.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

DECOCTUM QUERCUS

(Dec. Querc.)

Decoction of Oak Bark

	<i>Metric</i>	<i>Imperial</i>
Oak Bark, bruised	62.5 g.	1½ oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Boil the oak bark in a covered vessel for ten minutes with 1000 millilitres (20 fluid ounces) of distilled water; strain, and pour sufficient distilled water over the contents of the strainer to produce the required volume.

DECOCTUM SARSÆ COMPOSITUM

(Dec. Sars. Co.)

Compound Decoction of Sarsaparilla

	<i>Metric</i>	<i>Imperial</i>
Sarsaparilla, cut transversely and bruised	125.0 g.	2 oz. 219 gr.
Sassafras Root, in chips	12.5 g.	109 gr.
Guaiacum Wood, in shavings	12.5 g.	109 gr.
Liquorice, unpeeled, bruised	12.5 g.	109 gr.
Mezereon, cut small	6.25 g.	54½ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Macerate the sarsaparilla, guaiacum wood, sassafras root, liquorice and mezereon for one hour with 1500 millilitres (30 fluid ounces) of distilled water, then boil for ten minutes, cool, strain, and, if necessary, pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.—60 to 240 millilitres (2 to 8 fluid ounces).

When compound decoction of sarsaparilla (Decoctum Sarsæ Compositum) is prescribed, either the above preparation, or Decoctum Sarsæ Compositum Concentratum diluted with seven times its volume of distilled water, may be dispensed.

DECOCTUM SARSÆ COMPOSITUM CONCENTRATUM

(Dec. Sars. Co. Conc.)

Concentrated Compound Decoction of Sarsaparilla

	<i>Metric</i>	<i>Imperial</i>
Sarsaparilla, cut transversely and bruised	1000 g.	20 oz.
Sassafras Root, in chips.	100 g.	2 oz.
Guaiacum Wood, in shavings	100 g.	2 oz.
Liquorice, unpeeled, bruised	100 g.	2 oz.
Mezereon, cut small	50 g.	1 oz.
Alcohol (90 per cent.)	225 ml.	4½ fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add the sarsaparilla to 5000 millilitres (100 fluid ounces) of distilled water at 70° and infuse for one hour at that temperature; repeat the infusion twice with similar quantities of water. Exhaust the other solid ingredients by boiling with distilled water. Mix the three infusions with the decoction and rapidly evaporate the mixture to a volume of 750 millilitres (15 fluid ounces); add the alcohol, set aside for fourteen days, filter, and pour sufficient distilled water over the contents of the filter to produce the required volume.

Dose.—8 to 30 millilitres (¼ to 1 fluid ounce).

This concentrated decoction when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength to compound decoction of sarsaparilla, but contains about 2.8 per cent. v/v of alcohol (90 per cent.).

DECOCTUM SCOPARI

(Dec. Scopar.)

Decoction of Scoparium

Synonym—Decoction of Broom.

	<i>Metric</i>	<i>Imperial</i>
Scoparium, bruised	50 g.	1 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the scoparium for ten minutes with 1000 millilitres (20 fluid ounces) of distilled water in a covered vessel; strain, and pour sufficient distilled water over the contents of the strainer to produce the required volume.

Dose.— 60 to 120 millilitres (2 to 4 fluid ounces).

When decoction of scoparium (*Decoctum Scoparii*) is prescribed, either the above preparation, or *Decoctum Scoparii Concentratum* diluted with seven times its volume of distilled water, may be dispensed.

DECOCTUM SCOPARII CONCENTRATUM

(*Dec. Scopar. Conc.*)

Concentrated Decoction of Scoparium

Synonym—Concentrated Decoction of Broom.

		<i>Metric</i>	<i>Imperial</i>
Scoparium, cut small	400 g.	8 oz.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Exhaust the scoparium by boiling for twenty minutes with successive quantities each of about 2000 millilitres (40 fluid ounces) of distilled water. Evaporate the mixed liquids to 750 millilitres (15 fluid ounces), allow to cool, add the alcohol and sufficient distilled water to produce the required volume. Allow to stand for not less than fourteen days and filter.

Dose.— 8 to 16 millilitres (2 to 4 fluid drachms).

This concentrated decoction when diluted with seven times its volume of distilled water yields a preparation which is approximately equivalent in strength to decoction of scoparium, but contains about 3 per cent. v/v of alcohol (90 per cent.).

ELIXIRIA

Elixirs

Elixirs are aromatic liquid preparations frequently containing considerable quantities of alcohol. They range from simple sweetening and flavouring agents, suitable for general use in mixtures, emulsions and similar preparations, to compound elixirs forming convenient means of administering potent or nauseous drugs in palatable form. Alcoholic elixirs should be well diluted at the time of administration.

Elixirs should be bright and clear; when necessary, as for example when the formula includes volatile oil, the product may be shaken with purified talc or kaolin and filtered through paper, precautions being taken to avoid evaporation of alcohol.

ELIXIR ÆTHYLMORPHINÆ ET TERPINI

(Elix. Æthylmorph. et Terpin.)

Elixir of Ethylmorphine and Terpin

	<i>Metric</i>	<i>Imperial</i>
Ethylmorphine Hydrochloride ..	2 g.	17½ gr.
Terpin Hydrate	5 g.	43½ gr.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Glycerin	250 ml.	5 fl. oz.
Syrup of Wild Cherry .. .	to 1000 ml.	to 20 fl. oz.

Dissolve the ethylmorphine hydrochloride and the terpin hydrate in the alcohol; add the glycerin and sufficient syrup of wild cherry to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR ALETRIDIS

(Elix. Aletr.)

Elixir of Aletris

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Aletris ..	250 ml.	5 fl. oz.
Liquid Extract of Liquorice ..	60 ml.	1 fl. oz. 96 m.
Simple Elixir	450 ml.	9 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the liquid extracts with the elixir, add the distilled water, allow to stand and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR ANISI

(Elix. Anis.)

Elixir of Anise

	<i>Metric</i>	<i>Imperial</i>
Oil of Anise	3·13 ml.	30 m.
Oil of Fennel	0·52 ml.	5 m.
Oil of Bitter Almond without Hydrocyanic Acid	0·13 ml.,	1¼ m.
Alcohol (90 per cent.)	250·0 ml.	5 fl. oz.
Syrup	625·0 ml.	12½ fl. oz.
Distilled Water	to 1000·0 ml.	to 20 fl. oz.

Mix the oils with the alcohol, add the syrup and 125 millilitres (2½ fluid ounces) of distilled water, set aside for twelve hours and add sufficient distilled water to produce the required volume; add 25 grammes (½ ounce) of purified talc or kaolin, shake well and filter.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

ELIXIR AROMATICUM

(Elix. Aromat.)

Aromatic Elixir

Synonyms—Elixir Aurantii; Elixir Aurantii Compositum.

	<i>Metric</i>	<i>Imperial</i>
Oil of Orange	2.5 ml.	24 m.
Oil of Lemon	0.6 ml.	6 m.
Oil of Coriander	0.25 ml.	2½ m.
Oil of Anise	0.06 ml.	$\frac{3}{5}$ m.
Alcohol (90 per cent.)	250.0 ml.	5 fl. oz.
Syrup	375.0 ml.	7½ fl. oz.
Distilled Water to	1000.0 ml.	to 20 fl. oz.

Dissolve the oils in the alcohol and add the syrup gradually, shaking well after each addition; then add sufficient distilled water to produce the required volume; add 25 grammes (½ ounce) of purified talc or kaolin, shake and filter.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

ELIXIR BROMOFORMI

(Elix. Bromof.)

Elixir of Bromoform

Synonyms—Mistura Bromoformi Composita; Compound Mixture of Bromoform.

	<i>Metric</i>	<i>Imperial</i>
Bromoform	20 ml.	192 m.
Alcohol (90 per cent.)	50 ml.	1 fl. oz.
Tincture of Orange	50 ml.	1 fl. oz.
Compound Tincture of Cardamom	100 ml.	2 fl. oz.
Glycerin to	1000 ml.	to 20 fl. oz.

Dissolve the bromoform in the alcohol and tincture of orange, add the compound tincture of cardamom, and sufficient glycerin to produce the required volume.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

ELIXIR CINCHONÆ

(Elix. Cinchon.)

Elixir of Cinchona

	<i>Metric</i>	<i>Imperial</i>
Tincture of Cinchona	150 ml.	3 fl. oz.
Syrup	125 ml.	2½ fl. oz.
Glycerin	125 ml.	2½ fl. oz.
Aromatic Elixir to 1000 ml.	to 20 fl. oz.

Mix, allow to stand, and filter through a moistened filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Elixir Calisayæ is a similar preparation prepared with tincture of *Cinchona Calisaya* Weddell.

ELIXIR COCÆ

(Elix. Cocæ)

Elixir of Coca

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Coca	165 ml.	3 fl. oz. 144 m.
Simple Elixir to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

ELIXIR DIAMORPHINÆ ET PINI COMPOSITUM

(Elix. Diamorph. et Pini Co.)

Compound Elixir of Diamorphine and Pine

	<i>Metric</i>	<i>Imperial</i>
Oil of Pumilio Pine	8·3 ml.	80 m.
Terpin Hydrate	5·0 g.	43½ gr.
Diamorphine Hydrochloride ..	0·5 g.	4½ gr.
Alcohol (90 per cent.)	250·0 ml.	5 fl. oz.
Glycerin	250·0 ml.	5 fl. oz.
Compound Solution of Tartrazine	10·4 ml.	100 m.
Sucrose	400·0 g.	8 oz.
Distilled Water to 1000·0 ml.	to 20 fl. oz.

Dissolve the terpin hydrate and diamorphine hydrochloride in the alcohol, add the glycerin and oil of pumilio pine and shake vigorously. Add 300 millilitres (6 fluid ounces) of distilled water, shake with 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin and filter. Dissolve the sucrose in the filtrate, using gentle heat if necessary, add the compound solution of tartrazine and sufficient distilled water to produce the required volume.

It should be **stored** in amber-coloured bottles.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR DIAMORPHINÆ ET TERPINI

(Elix. Diamorph. et Terpin.)

Elixir of Diamorphine and Terpin

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	1 g.	8 $\frac{3}{4}$ gr.
Terpin Hydrate	5 g.	43 $\frac{3}{4}$ gr.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Glycerin	250 ml.	5 fl. oz.
Syrup of Wild Cherry	to 1000 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride and terpin hydrate in the alcohol, then add the glycerin and sufficient syrup of wild cherry to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR DIAMORPHINÆ ET TERPINI CUM APOMORPHINA

(Elix. Diamorph. et Terpin. c. Apomorph.)

Elixir of Diamorphine and Terpin with Apomorphine

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0·46 g.	4 gr.
Apomorphine Hydrochloride ..	0·57 g.	5 gr.
Terpin Hydrate	5·0 g.	43 $\frac{3}{4}$ gr.
Alcohol (90 per cent.)	250·0 ml.	5 fl. oz.
Glycerin	250·0 ml.	5 fl. oz.
Syrup of Wild Cherry	to 1000·0 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride, apomorphine hydrochloride and terpin hydrate in the alcohol, then add the glycerin and sufficient syrup of wild cherry to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR EPHEDRINÆ HYDROCHLORIDI

(Elix. Ephed. Hydrochlor.)

Elixir of Ephedrine Hydrochloride

	<i>Metric</i>	<i>Imperial</i>
Ephedrine Hydrochloride . .	4·6 g.	40 gr.
Distilled Water	83·3 ml.	1 fl. oz. 320 m.
Glycerin	250·0 ml.	5 fl. oz.
Compound Solution of Tartrazine	10·4 ml.	100 m.
Spirit of Chloroform	50·0 ml.	1 fl. oz.
Tincture of Lemon	50·0 ml.	1 fl. oz.
Alcohol (90 per cent.)	125·0 ml.	2 $\frac{1}{2}$ fl. oz.
Syrup	to 1000·0 ml.	to 20 fl. oz.

Dissolve the ephedrine hydrochloride in the distilled water and add the glycerin and compound solution of tartrazine, then add the tincture of lemon, the spirit of chloroform and sufficient syrup to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ELIXIR EUONYMI ET PULSATILLÆ

(Elix. Euonym. et Pulsat.)

Elixir of Euonymus and Pulsatilla

		<i>Metric</i>	<i>Imperial</i>
Tincture of Euonymus	125 ml.	2 $\frac{1}{2}$ fl. oz.
Tincture of Pulsatilla	125 ml.	2 $\frac{1}{2}$ fl. oz.
Simple Elixir	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

ELIXIR FORMATUM COMPOSITUM

(Elix. Form. Co.)

Compound Elixir of Formates

Synonyms—Elixir Formatum cum Strychnina; Elixir of Formates with Strychnine.

		<i>Metric</i>	<i>Imperial</i>
Sodium Formate	50.0 g.	1 oz.
Potassium Formate	50.0 g.	1 oz.
Solution of Strychnine Hydrochloride	20.8 ml.	200 m.
Simple Elixir	to 1000.0 ml.	to 20 fl. oz.

Dissolve the sodium and potassium formates in 800 millilitres (16 fluid ounces) of the simple elixir, add the solution of strychnine hydrochloride and sufficient simple elixir to produce the required volume, and filter if necessary.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

ELIXIR GUARANÆ

(Elix. Guarana.)

Elixir of Guarana

		<i>Metric</i>	<i>Imperial</i>
Tincture of Guarana	800.0 ml.	16 fl. oz.
Oil of Cinnamon	0.5 ml.	5 m.
Syrup	100.0 ml.	2 fl. oz.
Alcohol (60 per cent.)	to 1000.0 ml.	to 20 fl. oz.

Mix the syrup and oil of cinnamon, add the tincture of guarana and sufficient of the alcohol to produce the required volume; add 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, shake well and filter.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ELIXIR HÆMOGLOBINI

(Elix. Hæmoglob.)

Elixir of Hæmoglobin

	<i>Metric</i>	<i>Imperial</i>
Hæmoglobin	100.0 g.	2 oz.
Glycerin	100.0 ml.	2 fl. oz.
Alcohol (90 per cent.)	150.0 ml.	3 fl. oz.
Syrup	500.0 ml.	10 fl. oz.
Vanillin	0.23 g.	2 gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the hæmoglobin in a mixture of 250 millilitres (5 fluid ounces) of the syrup and 200 millilitres (4 fluid ounces) of the distilled water. Add the vanillin dissolved in the alcohol, the glycerin, the remainder of the syrup and sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

ELIXIR IPECACUANHÆ

(Elix. Ipecac.)

Elixir of Ipecacuanha

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Ipecacuanha	50 ml.	1 fl. oz.
Alcohol (90 per cent.)	50 ml.	1 fl. oz.
Glycerin	250 ml.	5 fl. oz.
Simple Elixir	50 ml.	1 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the liquid extract of ipecacuanha with the alcohol (90 per cent.) and glycerin, add the simple elixir and sufficient distilled water to produce the required volume; allow to stand for not less than three days and filter.

Dose.— 0.6 to 2 millilitres (10 to 30 minims).

This elixir contains approximately the same proportion of alkaloids as *Tinctura Ipecacuanhæ*.

ELIXIR OVOLECITHINI

(Elix. Ovocleithin.)

Elixir of Ovocleithin*Synonyms*—Elixir Lecithini; Elixir of Lecithin.

	<i>Metric</i>	<i>Imperial</i>
Ovocleithin	18.3 g.	160 gr.
Yolk of Egg	125.0 ml.	2½ fl. oz.
Glycerin	350.0 ml.	7 fl. oz.
Tincture of Lemon	18.75 ml.	180 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate the ovocleithin with the yolk of egg added gradually to form a smooth cream; add the glycerin and tincture of lemon; then add gradually, with constant trituration, sufficient distilled water to produce the required volume.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

ELIXIR PAPAINI

(Elix. Papain.)

Elixir of Papain

	<i>Metric</i>	<i>Imperial</i>
Papain	50 g.	1 oz.
Alcohol (90 per cent.)	150 ml.	3 fl. oz.
Distilled Water	450 ml.	9 fl. oz.
Aromatic Elixir	to 1000 ml.	to 20 fl. oz.

Macerate the papain with the alcohol and water for seven days, filter, and add sufficient aromatic elixir to produce the required volume.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

ELIXIR PEPSINI

(Elix. Pepsin.)

Elixir of Pepsin

	<i>Metric</i>	<i>Imperial</i>
Pepsin	50 g.	1 oz.
Alcohol (90 per cent.)	150 ml.	3 fl. oz.
Distilled Water	450 ml.	9 fl. oz.
Aromatic Elixir	to 1000 ml.	to 20 fl. oz.

Macerate the pepsin with the alcohol and water for seven days, filter, and add sufficient aromatic elixir to produce the required volume.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

ELIXIR PHENOBARBITONI

(Elix. Phenobarbiton.)

Elixir of Phenobarbitone

	<i>Metric</i>	<i>Imperial</i>
Phenobarbitone	5.0 g.	43 $\frac{3}{4}$ gr.
Alcohol (90 per cent.)	450.0 ml.	9 fl. oz.
Oil of Orange	4.0 ml.	38 $\frac{1}{2}$ m.
Oil of Lemon	1.0 ml.	9 $\frac{1}{2}$ m.
Oil of Coriander	0.4 ml.	4 m.
Oil of Anise	0.1 ml.	1 m.
Glycerin	350.0 ml.	7 fl. oz.
Compound Solution of Tartrazine	10.4 ml.	100 m.
Distilled Waterto	1000.0 ml.	to 20 fl. oz.

Dissolve the phenobarbitone and the oils in the alcohol, add the glycerin, the compound solution of tartrazine and sufficient distilled water to produce the required volume. Add 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, shake well and filter.

It should be **stored** in amber-coloured bottles.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

ELIXIR QUININÆ AMMONIATUM ET CINNAMOMI

(Elix. Quinin. Ammon. et Cinnam.)

Ammoniated Elixir of Quinine and Cinnamon

	<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	20.0 g.	175 gr.
Ammonium Carbonate	44.6 g.	390 gr.
Strong Solution of Ammonia	10.0 ml.	96 m.
Solution of Cochineal	20.0 ml.	192 m.
Spirit of Chloroform	30.0 ml.	288 m.
Oil of Cinnamon	2.1 ml.	20 m.
Alcohol (90 per cent.)	375.0 ml.	7 $\frac{1}{2}$ fl. oz.
Syrup of Orange	400.0 ml.	8 fl. oz.
Distilled Waterto	1000.0 ml.	to 20 fl. oz.

Dissolve the oil of cinnamon in the alcohol and spirit of chloroform, diffuse the quinine sulphate in the mixture, and add the ammonium carbonate previously dissolved in 150 millilitres (3 fluid ounces) of distilled water mixed with the strong solution of ammonia, the solution of cochineal and the syrup of orange; add, if necessary, sufficient distilled water to produce the required volume, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

ELIXIR SACCHARINI

(Elix. Saccharin.)

Elixir of Saccharin*Synonyms*—Elixir Glusidi; Elixir of Gluside.

	<i>Metric</i>	<i>Imperial</i>
Saccharin	50 g.	1 oz.
Sodium Bicarbonate	30 g.	262½ gr.
Alcohol (90 per cent.)	125 ml.	2½ fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add the saccharin to the sodium bicarbonate previously dissolved in 800 millilitres (16 fluid ounces) of distilled water; when effervescence ceases add the alcohol, filter and wash the filter with sufficient distilled water to produce the required volume.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

ELIXIR SENNÆ

(Elix. Senn.)

Elixir of Senna

Synonyms—Liquor Sennæ Leguminum Dulcis; Sweet Essence of Senna Pods.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Senna	500.0 ml.	10 fl. oz.
Sucrose	500.0 g.	10 oz.
Chloroform	2.6 ml.	25 m.
Oil of Coriander	0.2 ml.	2 m.
Tincture of Capsicum	2.1 ml.	20 m.
Alcohol (90 per cent.)	25.0 ml.	½ fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oil of coriander and the chloroform in the alcohol, add the tincture of capsicum and the liquid extract of senna, dissolve the sucrose in the mixture, and add sufficient distilled water to produce the required volume.

Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

ELIXIR SIMPLEX

(Elix. Simp.)

Simple Elixir

	<i>Metric</i>	<i>Imperial</i>
Tincture of Orange	75 ml.	1½ fl. oz.
Syrup	400 ml.	8 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the tincture of orange with the syrup, and add sufficient distilled water to produce the required volume; add 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, shake well and filter.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

ELIXIR THYMI

(Elix. Thym.)

Elixir of Thyme

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Thyme ..	125.0 ml.	2 $\frac{1}{8}$ fl. oz.
Ammonium Bromide	36.6 g.	320 gr.
Distilled Water	83.3 ml.	1 fl. oz. 320 m.
Spirit of Chloroform	83.3 ml.	1 fl. oz. 320 m.
Treacle	166.7 ml.	3 fl. oz. 160 m.
Glycerin	125.0 ml.	2 $\frac{1}{2}$ fl. oz.
Syrup to 1000.0 ml.	to 20 fl. oz.

Mix the liquid extract of thyme with the glycerin, treacle and spirit of chloroform; add the ammonium bromide dissolved in the distilled water and finally add sufficient syrup to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

ELIXIR VALERIANÆ

(Elix. Valerian.)

Elixir of Valerian

	<i>Metric</i>	<i>Imperial</i>
Simple Tincture of Valerian ..	300.0 ml.	6 fl. oz.
Liquid Extract of Liquorice ..	87.5 ml.	1 $\frac{3}{4}$ fl. oz.
Aromatic Elixir to 1000.0 ml.	to 20 fl. oz.

Mix, and filter if necessary.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ELIXIR VALERIANÆ COMPOSITUM

(Elix. Valerian. Co.)

Compound Elixir of Valerian

Synonyms—Elixir Bromidi et Valerianæ Compositum; Compound Elixir of Bromide and Valerian.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Valerian ..	31.2 ml.	300 m.
Potassium Bromide ..	17.1 g.	150 gr.
Chloral Hydrate	17.1 g.	150 gr.
Liquid Extract of Liquorice ..	20.8 ml.	200 m.
Oil of Orange ..	4.2 ml.	40 m.
Oil of Lemon	1.0 ml.	10 m.
Oil of Coriander ..	0.4 ml.	4 m.
Oil of Anise ..	0.1 ml.	1 m.
Alcohol (90 per cent.) ..	15.6 ml.	150 m.
Syrup	250.0 ml.	5 fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium bromide and chloral hydrate in 600 millilitres (12 fluid ounces) of distilled water, add the liquid extract of valerian, the liquid extract of liquorice, the syrup, and the oils previously dissolved in the alcohol. Add 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, shake well and filter; pass sufficient distilled water through the filter to produce the required volume.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

ELIXIR VIBURNI

(Elix. Viburn.)

Elixir of Black Haw

Synonym—Elixir Viburni Prunifolii.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Black Haw ..	125 ml.	2 $\frac{1}{2}$ fl. oz.
Compound Tincture of Cardamom ..	75 ml.	1 $\frac{1}{2}$ fl. oz.
Aromatic Elixir	to 1000 ml.	to 20 fl. oz.

Mix, set aside for a few days, and filter.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

ELIXIR VIBURNI ET HYDRASTIS

(Elix. Viburn. et Hydrast.)

Elixir of Black Haw and Hydrastis

Synonyms—Elixir Viburni Compositum; Compound Elixir of Viburnum Prunifolium.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Black Haw ..	500.0 ml.	10 fl. oz.
Extract of Hydrastis ..	17.5 g.	153 gr.
Oil of Coriander	5.0 ml.	48 m.
Oil of Caraway	5.0 ml.	48 m.
Glycerin	to 1000.0 ml.	to 20 fl. oz.

Dissolve the extract of hydrastis and the oils of coriander and caraway in the liquid extract of black haw, and add sufficient glycerin to produce the required volume; filter if necessary.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EMPLASTRA**Plasters**

Plasters consist of medicaments incorporated with a plastic, resinous or rubber basis and may be spread upon leather known as "plaster skin," calico, linen, holland, or other suitable material. The plaster so produced is designed to maintain a medicinal substance in close contact with the skin so that by prolonged contact the medicament may be slowly absorbed, to act as a protective, or to assist in the approximation of the edges of wounds.

When spreading plasters, the leather should be previously smoothed with a hot iron, the mass melted over a water-bath and precautions taken to avoid destroying alkaloidal principles or dissipating volatile ingredients by excessive heat. The plaster-mass should be spread thinly upon the supporting material in the proportion of about 10 grains to the square inch, a margin of the material at least three-quarters of an inch wide being left bare to avoid extension of the mass over the edge of the plaster.

Plasters having a basis of plaster of lead, colophony, or soap, require to be warmed before application; those having a rubber basis adhere closely by the warmth of the body. Plasters intended to raise a blister are made soft in order that they may be removed easily from the vesicated surface. They are usually spread upon plaster of lead, and warmed before application to the skin. For use in minor surgery and as protective agents, plasters are prepared spread with a solution of isinglass or rubber, the usual backings being felt of various thicknesses, sometimes called "elephant plaster," linen, muslin, or silk.

In tropical and sub-tropical climates more or less hard soap, colophony, or yellow beeswax may be used for the preparation of plaster-masses to meet conditions of temperature, but the required proportion of the active ingredient must be maintained.

EMPLASTRUM BELLADONNÆ VIRIDÆ

(Emp. Bellad. Vir.)

Green Belladonna Plaster

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Belladonna ..	250 g.	4 oz.
Chlorophyll	a sufficient	quantity
Rubber Adhesive Plaster, of commerce	to 1000 g.	to 16 oz.

Mix the dry extract of belladonna with 625 grammes (10 ounces) of rubber adhesive plaster previously melted on a water-bath, then add sufficient chlorophyll to produce a bright green colour and sufficient rubber adhesive plaster to produce the required weight.

Green belladonna plaster contains about 0.25 per cent. of the alkaloids of belladonna leaf.

EMPLASTRUM CALEFACIENS

(Emp. Calefac.)

Warming Plaster

			<i>Metric</i>	<i>Imperial</i>
Cantharidin	0.2 g.	1½ gr.
Chloroform	20.0 ml.	154 m.
Olive Oil	40.0 ml.	307 m.
Plaster of Colophony	940.0 g.	15 oz. 17½ gr.

Dissolve the cantharidin in the chloroform, add the olive oil, and mix with the plaster of colophony previously melted on a water-bath.

EMPLASTRUM CAPSICI

(Emp. Capsic.)

Plaster of Capsicum

			<i>Metric</i>	<i>Imperial</i>
Oleoresin of Capsicum	20 g.	140 gr.
Plaster of Colophony	1000 g.	16 oz.

Mix the oleoresin of capsicum with the melted plaster of colophony.

EMPLASTRUM CAPSICI ELASTICUM

(Emp. Capsic. Elast.)

Rubber Plaster of Capsicum

			<i>Metric</i>	<i>Imperial</i>
Oleoresin of Capsicum	20 g.	140 gr.
Rubber Adhesive Plaster, of commerce	1000 g.	16 oz.

Mix the oleoresin of capsicum with the melted rubber adhesive plaster.

EMPLASTRUM FERRI

(Emp. Ferr.)

Iron Plaster

Synonyms—Emplastrum Roborans; Strengthening Plaster.

			<i>Metric</i>	<i>Imperial</i>
Brown Precipitated Ferric Oxide			100 g.	1 oz.
Burgundy Pitch	200 g.	2 oz.
Plaster of Lead	800 g.	8 oz.

Melt together the burgundy pitch and plaster of lead, add the brown

precipitated ferric oxide and stir constantly until the mixture stiffens on cooling.

EMPLASTRUM HYDRARGYRI

(Emp. Hydrarg.)

Mercurial Plaster

	<i>Metric</i>	<i>Imperial</i>
Mercury	328 g.	5 oz. 108½ gr.
Olive Oil	18 g.	126 gr.
Sublimed Sulphur	2 g.	14 gr.
Plaster of Lead	652 g.	10 oz. 189 gr.

Heat the olive oil with the sulphur until a reddish-brown liquid is obtained; with this solution triturate the mercury until metallic globules are no longer visible; add the plaster of lead, previously melted, and mix.

EMPLASTRUM LYTTÆ

(Emp. Lyttæ)

Plaster of Cantharides

	<i>Metric</i>	<i>Imperial</i>
Cantharides, in powder	350 g.	3½ oz.
Yellow Beeswax	200 g.	2 oz.
Lard	200 g.	2 oz.
Colophony	200 g.	2 oz.
Plaster of Soap	50 g.	½ oz.

Melt the colophony, add the plaster of soap and afterwards the yellow beeswax and the lard. Sprinkle the cantharides into the melted mixture and stir until cold.

EMPLASTRUM MENTHOLIS

(Emp. Menthol.)

Plaster of Menthol

	<i>Metric</i>	<i>Imperial</i>
Menthol	150 g.	3 oz.
Yellow Beeswax	100 g.	2 oz.
Colophony	750 g.	15 oz.

Melt the beeswax and colophony together; when the mixture has cooled to about 70°, add the menthol and stir until dissolved.

EMPLASTRUM PICIS

(Emp. Pic.)

Plaster of Pitch*Synonym*—Poor Man's Plaster.

	<i>Metric</i>	<i>Imperial</i>
Burgundy Pitch	520 g.	13 oz.
Olibanum	260 g.	6½ oz.
Colophony	90 g.	2½ oz.
Yellow Beeswax	90 g.	2½ oz.
Olive Oil	40 g.	1 oz.
Distilled Water	40 g.	1 oz.

Add the olive oil and the water to the olibanum, burgundy pitch, colophony and beeswax, previously melted together, and evaporate, with constant stirring, to a proper consistence.

EMPLASTRUM SALICYLICUM COMPOSITUM

(Emp. Salicyl. Co.)

Compound Salicylic Plaster

	<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	200 g.	3 oz.
Extract of Cannabis	100 g.	1½ oz.
Rubber Adhesive Plaster, of commerce	700 g.	10½ oz.

Dry the extract of cannabis on a water-bath, mix it intimately with the rubber adhesive plaster, previously melted on a water-bath, then add the finely powdered salicylic acid and mix thoroughly.

EMPLASTRUM SALICYLICUM COMPOSITUM FORTIUS

(Emp. Salicyl. Co. Fort.)

Stronger Compound Salicylic Plaster

	<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	400 g.	6 oz.
Extract of Cannabis	200 g.	3 oz.
Rubber Adhesive Plaster, of commerce	400 g.	6 oz.

Dry the extract of cannabis on a water-bath, mix it intimately with the rubber adhesive plaster, previously melted on a water-bath, then add the finely powdered salicylic acid and mix thoroughly.

EMPLASTRUM SALICYLICUM ELASTICUM**(Emp. Salicyl. Elast.)****Rubber Salicylic Plaster**

	<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	100 g.	1½ oz.
Rubber Adhesive Plaster, of commerce	900 g.	13½ oz.

Incorporate the salicylic acid, finely powdered, with the rubber adhesive plaster, previously melted on a water-bath.

Rubber salicylic plasters may also be prepared containing other proportions of salicylic acid, varying from 5 to 40 per cent.

EMPLASTRUM SAPONIS**(Emp. Sap.)****Plaster of Soap**

	<i>Metric</i>	<i>Imperial</i>
Hard Soap	140 g.	2 oz. 105 gr.
Plaster of Lead	835 g.	13 oz. 157½ gr.
Colophony	25 g.	175 gr.

Melt together the colophony and the plaster of lead at as low a temperature as possible and incorporate the hard soap.

EMPLASTRUM SAPONIS FUSCUM**(Emp. Sap. Fusc.)****Brown Plaster of Soap***Synonym*—Emplastrum Cerati Saponis.

	<i>Metric</i>	<i>Imperial</i>
Curd Soap, in powder	100 g.	10 oz.
Yellow Beeswax	125 g.	12½ oz.
Olive Oil	200 ml.	20 fl. oz.
Lead Monoxide	150 g.	15 oz.
Vinegar, of commerce	1600 ml.	160 fl. oz.

Boil the vinegar and lead monoxide together, stirring constantly, until the oxide has combined with the acid, then add the soap and boil again until most of the moisture is evaporated; finally add the wax and oil melted together, and stir the whole continuously, maintaining the heat until, by the evaporation of the remaining moisture, the product has acquired the proper consistence for a plaster.

EMULSIONES**Emulsions**

An emulsion consists of two liquid phases, one of which is subdivided finely and dispersed in the other, the system being made more or less permanent by the presence of an emulsifying agent (emulgent). It is possible to have two types of emulsions containing water and oil—one in which water or an aqueous solution is the continuous phase (oil-in-water emulsions) and one in which oil or fat is the continuous phase (water-in-oil emulsions). The latter type is rarely employed for internal administration, but is used in the form of liniments, embrocations and ointments. The emulgents for this type may be wool fat, beeswax, or a soap with a divalent or trivalent base, such as calcium or zinc oleate or stearate. External applications are also prepared in the form of oil-in-water emulsions, a soap with a monovalent base, such as sodium or potassium, being used as the emulgent, but the oil-in-water type constitutes the usual form for the internal administration of oils as emulsions. This type is particularly suitable for that purpose since the oil is dispersed in a continuous aqueous medium which may be sweetened and flavoured, and thus any nauseous and greasy characters can be disguised. Moreover, such emulsions may be diluted readily with water. The following considerations apply to this type only, the emulgents commonly used being mucilages of acacia and tragacanth, decoctions of Irish moss or agar, yolk of egg, or saponins.

The following factors govern the rate of creaming in emulsions:—

(a) The difference in density between the disperse and continuous phases; the greater the difference, the greater the tendency to cream. (b) The radius of the globules of the disperse phase; the smaller the size of the globules, the less the tendency to cream. For this reason it is important when preparing a hand-made emulsion to make a good primary emulsion before diluting. On a large scale, special emulsion mills or homogenisers are employed which are capable of producing uniform globules of a very much smaller size than can be made in a mortar by hand. As the larger globules of oil are broken up into smaller ones, the viscosity of the emulsion as a whole increases and if the quantity of gum in the formula is that required for a hand-made emulsion, the constituents when passed through a mill may form an unworkable mass because of its extreme viscosity. (c) The viscosity of the continuous phase; the greater the viscosity, the less the tendency to cream. Decoction of chondrus or mucilage of tragacanth is often included in the formulæ of acacia emulsions for this purpose. (d) The ratio of disperse to continuous phase; as the proportion of the former increases so the tendency to cream will decrease. Thus, an emulsion containing fifty per cent. of oil will require proportionately less gum than one containing only twenty-five per cent.

The method of preparation of emulsions depends upon the quantity of material to be manipulated and upon the emulgent employed. Small quantities may be produced by brisk and light trituration using a

flat-headed pestle in an ample-sized mortar. The first object should be the production of a concentrated primary emulsion and dilution should not be attempted before this is accomplished. The procedure will vary with different emulgents. When preparing an emulsion of the British Pharmaceutical Codex with the aid of a homogenising machine, the quantity of emulsifying agent specified in the formula may be reduced if necessary, provided that the final product contains the correct proportions of other constituents and that its viscosity as a whole is approximately equal to that of one made from the formula by hand in a mortar. In cases where a preservative is required, benzoic acid, 0.4 per cent., or a suitable derivative of benzoic acid or salicylic acid, may be added.

The following are the principal substances employed as emulsifying agents:—

Powdered Acacia is generally employed in preference to mucilage of acacia and is probably the best emulent for emulsions of the oil-in-water type for internal use. In making the primary emulsion, one part of powdered gum is required for (a) every four parts of a fixed oil, provided the percentage of fixed oil in the finished product is not less than twenty-five per cent., (b) every two parts of a volatile oil, soft paraffin, or an oleo-resin such as copaiba, or extract of male fern, (c) every one part of a wax such as spermaceti. The quantity of water required is always exactly twice the quantity of gum used. Measure the oil and drain it into the dry mortar, add the powdered gum, mix quickly and immediately add the water; triturate very lightly and briskly until complete emulsification ensues. It is important that the powdered gum and oil should not be left in contact for longer than is necessary to mix them. For the emulsification of soft paraffin and waxes, a warm mortar and warm water should be used.

Decoction of Chondrus emulsions are prone to fermentation and separation unless inhibiting substances are added. Decoction of chondrus is a more efficient emulsifying agent when allowed to stand for about eighteen hours before use. Six to eight parts of the decoction, set to the consistence of a thin jelly, suffice for the emulsification of eight parts of oil. The oil should be added in portions, shaking or beating strongly by means of any suitable machine after each addition.

Yolk of Egg possesses approximately double the emulsifying power of powdered acacia, volume for weight. The yolk of an egg of average size measures from four to five fluid drachms and suffices for the emulsification of at least four fluid ounces of fixed oil or two fluid ounces of volatile oil. Oils should be added gradually to the requisite quantity of yolk of egg, freed from albumen and previously triturated in a mortar to a perfectly smooth consistence, distilled water being added in small portions if the emulsion thickens inconveniently. Emulsions prepared with yolk of egg are not so liable to separate upon the addition of alcoholic preparations, acid salts, diluted acids, glycerin, syrups or large quantities of soluble salts as are those prepared with acacia. Yolk

of egg is, therefore, a suitable agent for the preparation of turpentine liniments containing acetic acid. Yolk of egg may be preserved by mixing it with an equal volume of glycerin and by this means it can be kept in a suitable condition ready for use; the emulsifying power of the mixture is approximately equivalent to that of powdered acacia. If desired, flavouring agents such as saccharin or aromatic oils may be incorporated with the yolk of egg before admixture with the glycerin.

Mucilage of Tragacanth produces coarse emulsions and is, therefore, rarely used except, in conjunction with other emulsifying agents, to increase the viscosity and prevent creaming.

Saponins, generally in the form of the tinctures and liquid extracts of quillaia and senega, are sometimes employed as emulgents, usually for emulsions intended for external application from which it is desirable to exclude mucilaginous matter. In consequence of their therapeutic activity they should only be employed for preparations intended for internal use when so ordered. These agents may be employed with advantage for the emulsification of small quantities of oils or for preventing the complete separation of oil when adding alcoholic solutions of volatile oils to aqueous liquids. They are unsatisfactory for preparations containing appreciable quantities of oil since they do not make the continuous phase sufficiently viscous to prevent creaming. Tragacanth can be added with advantage for this purpose. One part of tincture of quillaia will emulsify eight parts of fixed oil or one part of volatile oil. The requisite quantity of tincture of quillaia should be diluted with two parts of water and thoroughly shaken in an ample-sized bottle with the oil until emulsification ensues. Saponin may be used with advantage in place of tincture of quillaia for the emulsification of fixed oils in creams or lotions. Four grains of saponin, dissolved in 120 minims of distilled water and shaken with 1 fluid ounce of fixed oil, produces a satisfactory emulsion. Emulsions made with quillaia or saponin are not affected by the addition of substances liable to 'crack' acacia emulsions.

EMULSIO ACRIFLAVINÆ

(Emuls. Acriflavin.)

Emulsion of Acriflavine

	<i>Metric</i>	<i>Imperial</i>
Acriflavine	1 g.	8 $\frac{3}{4}$ gr.
White Beeswax	41 g.	360 gr.
Distilled Water	250 ml.	5 fl. oz
Liquid Paraffin	750 ml.	15 fl. oz

Melt the white beeswax in the liquid paraffin, and add with constant stirring a warm solution of the acriflavine in the distilled water; stir until cold.

EMULSIO CHLOROFORMI

(Emuls. Chlorof.)

Emulsion of Chloroform

	<i>Metric</i>	<i>Imperial</i>
Chloroform	50 ml.	1 fl. oz.
Tincture of Quillaia	20 ml.	192 m.
Mucilage of Tragacanth	50 ml.	1 fl. oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Shake the chloroform with the tincture of quillaia, add the mucilage of tragacanth, shake well and add gradually sufficient distilled water to produce the required volume, shaking well after each addition.

Dose.—0·3 to 2 millilitres (5 to 30 minims).

EMULSIO MENTHÆ PIPERITÆ

(Emuls. Menth. Pip.)

Emulsion of Peppermint

	<i>Metric</i>	<i>Imperial</i>
Oil of Peppermint	100 ml.	2 fl. oz.
Tincture of Quillaia	50 ml.	1 fl. oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Add the oil of peppermint to the tincture of quillaia, shake, and add the distilled water gradually, shaking well after each addition.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

EMULSIO OLEI ARACHIS

(Emuls. Ol. Arach.)

Emulsion of Arachis Oil*Synonym*—Marylebone Cream (Improved).

	<i>Metric</i>	<i>Imperial</i>
Arachis Oil	475·0 ml.	9½ fl. oz.
Solution of Irradiated Ergosterol	25·0 ml.	½ fl. oz.
Acacia, in powder	125·0 g.	2½ oz.
Tragacanth, in powder	6·9 g.	60 gr.
Benzoic Acid	0·6 g.	5 gr.
Elixir of Saccharin	4·2 ml.	40 m.
Distilled Water to 1000·0 ml.		to 20 fl. oz.

'Triturate quickly the arachis oil and solution of irradiated ergosterol with the acacia and tragacanth; without delay add in one quantity 250 millilitres (5 fluid ounces) of distilled water and stir briskly until emulsified. Add the elixir of saccharin, the benzoic acid dissolved in hot distilled water, and sufficient distilled water to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

EMULSIO OLEI MORRHUÆ

(Emuls. Ol. Morrh.)

Emulsion of Cod-liver Oil

	<i>Metric</i>	<i>Imperial</i>
Cod-liver Oil	500.0 ml.	10 fl. oz.
Acacia, in powder	125.0 g.	2½ oz.
Tragacanth, in powder ..	6.9 g.	60 gr.
Oil of Bitter Almond without		
Hydrocyanic Acid	1.0 ml.	10 m.
Elixir of Saccharin	2.1 ml.	20 m.
Chloroform	2.1 ml.	20 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate quickly the cod-liver oil with the acacia and tragacanth; without delay add in one quantity 250 millilitres (5 fluid ounces) of distilled water and stir briskly until emulsified. Add the elixir of saccharin, oil of bitter almond, chloroform and sufficient distilled water to produce the required volume.

Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

EMULSIO OLEI MORRHUÆ CUM GLYCEROPHOSPHATIBUS

(Emuls. Ol. Morrh. c. Glycerophosph.)

Emulsion of Cod-liver Oil with Glycerophosphates

	<i>Metric</i>	<i>Imperial</i>
Cod-liver Oil	500.0 ml.	10 fl. oz.
Iron Glycerophosphate	4.6 g.	40 gr.
Solution of Sodium Glycerophosphate	9.1 g.	80 gr.
Solution of Potassium Glycerophosphate	9.1 g.	80 gr.
Glycerophosphoric Acid ..	10.4 ml.	100 m.
Calcium Glycerophosphate ..	9.1 g.	80 gr.
Magnesium Glycerophosphate ..	4.6 g.	40 gr.
Acacia, in powder	125.0 g.	2½ oz.
Tragacanth, in powder	6.9 g.	60 gr.
Elixir of Saccharin	4.1 ml.	40 m.
Tincture of Benzoin	10.4 ml.	100 m.
Chloroform	1.6 ml.	15 m.
Oil of Bitter Almond without		
Hydrocyanic Acid	1.0 ml.	10 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the iron glycerophosphate in 300 millilitres (6 fluid ounces) of distilled water, add the solution of sodium glycerophosphate, the solution of potassium glycerophosphate and the glycerophosphoric acid, and suspend the calcium and magnesium glycerophosphates in

the mixture. Triturate quickly the cod-liver oil with the acacia and tragacanth; without delay add in one quantity the glycerophosphates suspension and stir briskly until emulsified. Add the other ingredients and sufficient distilled water to produce the required volume.

Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

EMULSIO OLEI MORRHUÆ CUM HYPOPHOSPHITIBUS

(Emuls. Ol. Morrh. c. Hypophosph.)

Emulsion of Cod-liver Oil with Hypophosphites

Synonyms—Emulsio Olei Morrhue Composita; Compound Emulsion of Cod-liver Oil.

	<i>Metric</i>	<i>Imperial</i>
Cod-liver Oil	500.0 ml.	10 fl. oz.
Sodium Hypophosphite ..	18.3 g.	160 gr.
Calcium Hypophosphite ..	18.3 g.	160 gr.
Acacia, in powder	125.0 g.	2 $\frac{1}{2}$ oz.
Tragacanth, in powder ..	6.9 g.	60 gr.
Elixir of Saccharin	4.1 ml.	40 m.
Tincture of Benzoin	10.4 ml.	100 m.
Chloroform	1.6 ml.	15 m.
Oil of Bitter Almond without		
Hydrocyanic Acid	1.0 ml.	10 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate quickly the cod-liver oil with the acacia and tragacanth; without delay add in one quantity a solution of the hypophosphites in 250 millilitres (5 fluid ounces) of distilled water and stir briskly until emulsified. Add the other ingredients and sufficient distilled water to produce the required volume.

Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

EMULSIO OLEI MORRHUÆ ET CREOSOTI

(Emuls. Ol. Morrh. et Creosot.)

Emulsion of Cod-liver Oil and Creosote

	<i>Metric</i>	<i>Imperial</i>
Creosote	8.3 ml.	80 m.
Cod-liver Oil	333.3 ml.	6 fl. oz. 320 m.
Acacia, in powder	150.0 g.	3 oz.
Tragacanth, in powder ..	10.0 g.	87 $\frac{1}{2}$ gr.
Chloroform	1.2 ml.	12 m.
Tincture of Benzoin	25.0 ml.	$\frac{1}{2}$ fl. oz.
Oil of Pumilio Pine	0.3 ml.	3 m.
Glycerin	100.0 ml.	2 fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate quickly the cod-liver oil and creosote with the acacia and tragacanth; without delay add in one quantity 200 millilitres (4 fluid ounces) of distilled water and stir briskly until emulsified. Add the oil of pumilio pine, chloroform, tincture of benzoin, glycerin and sufficient distilled water to produce the required volume.

Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

EMULSIO OLEI OLIVÆ

(Emuls. Ol. Oliv.)

Emulsion of Olive Oil

	<i>Metric</i>	<i>Imperial</i>
Olive Oil	500.0 ml.	10 fl. oz.
Acacia, in powder	125.0 g.	2½ oz.
Tragacanth, in powder	6.9 g.	60 gr.
Elixir of Saccharin	2.1 ml.	20 m.
Tincture of Benzoin	10.4 ml.	100 m.
Chloroform	2.1 ml.	20 m.
Oil of Bitter Almond without		
Hydrocyanic Acid	1.0 ml.	10 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate quickly the olive oil with the acacia and tragacanth; without delay add in one quantity 250 millilitres (5 fluid ounces) of distilled water and stir briskly until emulsified. Add the other ingredients and sufficient distilled water to produce the required volume.

Dose.— 8 to 30 millilitres ($\frac{1}{4}$ to 1 fluid ounce).

EMULSIO OLEI RICINI AROMATICI

(Emuls. Ol. Ricin. Aromat.)

Emulsion of Aromatic Castor Oil

	<i>Metric</i>	<i>Imperial</i>
Aromatic Castor Oil .. .	300 ml.	6 fl. oz.
Acacia, in powder	75 g.	1½ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Triturate quickly the aromatic castor oil with the acacia; without delay add in one quantity 150 millilitres (3 fluid ounces) of distilled water and stir briskly until emulsified. Gradually add sufficient distilled water to produce the required volume.

Dose.— 30 to 60 millilitres (1 to 2 fluid ounces).

EMULSIO PARAFFINI LIQUIDI ALKALINA**(Emuls. Paraff. Liq. Alk.)****Alkaline Emulsion of Liquid Paraffin**

	<i>Metric</i>	<i>Imperial</i>
Mixture of Magnesium Hydroxide	250 ml.	5 fl. oz.
Emulsion of Liquid Paraffin with Agar to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).**EMULSIO PARAFFINI LIQUIDI COMPOSITA****(Emuls. Paraff. Liq. Co.)****Compound Emulsion of Liquid Paraffin***Synonym*—Emulsion of Liquid Paraffin with Agar and Phenolphthalein.

	<i>Metric</i>	<i>Imperial</i>
Phenolphthalein	3·4 g.	30 gr.
Emulsion of Liquid Paraffin with Agar	to 1000·0 ml.	to 20 fl. oz.

Reduce the phenolphthalein to fine powder and mix it with the emulsion.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).**EMULSIO PARAFFINI LIQUIDI CUM AGAR****(Emuls. Paraff. Liq. c. Agar)****Emulsion of Liquid Paraffin with Agar**

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	500·0 ml.	10 fl. oz.
Agar	7·5 g.	66 gr.
Acacia, in powder	25·0 g.	$\frac{1}{2}$ oz.
Tragacanth, in powder	2·5 g.	22 gr.
Benzoic Acid	1·7 g.	15 gr.
Vanillin, in powder	0·5 g.	$4\frac{1}{2}$ gr.
Oil of Lemon	1·0 ml.	10 m.
Glycerin	50·0 ml.	1 fl. oz.
Distilled Water to 1000·0 ml.	to 20 fl. oz.

Add the agar to 400 millilitres (8 fluid ounces) of the distilled water and boil gently until dissolved; if necessary, replace the water lost by

evaporation, then dissolve the benzoic acid in the mucilage and strain while hot. Warm the liquid paraffin and triturate it with the acacia, tragacanth and vanillin previously mixed; without delay add the strained mucilage in one quantity while hot and stir briskly until cold. Then add the glycerin, oil of lemon and sufficient distilled water to produce the required volume.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

EMULSIO PARAFFINI LIQUIDI CUM GLYCEROPHOSPHATIBUS

(Emuls. Paraff. Liq. c. Glycerophosph.)

Emulsion of Liquid Paraffin with Glycerophosphates

Synonyms—Emulsio Petrolei cum Glycerophosphatibus; Emulsion of Petroleum with Glycerophosphates.

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	500.0 ml.	10 fl. oz.
Iron Glycerophosphate	4.5 g.	40 gr.
Solution of Sodium Glycerophosphate	9.1 g.	80 gr.
Solution of Potassium Glycerophosphate	9.1 g.	80 gr.
Glycerophosphoric Acid	10.4 ml	100 m.
Calcium Glycerophosphate	9.1 g.	80 gr.
Magnesium Glycerophosphate	4.5 g.	40 gr.
Acacia, in powder	125.0 g.	2½ oz.
Tragacanth, in powder	6.9 g.	60 gr.
Elixir of Saccharin	2.1 ml	20 m.
Chloroform	2.1 ml	20 m.
Vanillin, in powder	0.03 g.	¼ gr.
Distilled Waterto	1000.0 ml	to 20 fl. oz.

Dissolve the iron glycerophosphate in 300 millilitres (6 fluid ounces) of distilled water, add the solution of sodium glycerophosphate, the solution of potassium glycerophosphate and the glycerophosphoric acid, and suspend the calcium and magnesium glycerophosphates in the mixture. Triturate quickly the liquid paraffin with the acacia, tragacanth and vanillin; without delay add in one quantity the glycerophosphates suspension and stir briskly until emulsified. Add the other ingredients and sufficient distilled water to produce the required volume.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

EMULSIO PARAFFINI LIQUIDI CUM HYPOPHOSPHITIBUS

(Emuls. Paraff. Liq. c. Hypophosph.)

Emulsion of Liquid Paraffin with Hypophosphites

Synonyms—Emulsio Petrolei cum Hypophosphitibus; Emulsion of Petroleum with Hypophosphites.

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	500.0 ml.	10 fl. oz.
Calcium Hypophosphite	18.3 g.	160 gr.
Sodium Hypophosphite	18.3 g.	160 gr.
Acacia, in powder	125.0 g.	2½ oz.
Tragacanth, in powder	10.0 g.	87½ gr.
Oil of Cinnamon	2.0 ml.	20 m.
Elixir of Saccharin	3.2 ml.	30 m.
Distilled Waterto 1000.0 ml.	to 20 fl. oz.

Triturate quickly the liquid paraffin and the oil of cinnamon with the acacia and tragacanth; without delay add in one quantity a solution of the hypophosphites in 250 millilitres (5 fluid ounces) of distilled water and stir briskly until emulsified. Add the elixir of saccharin and sufficient distilled water to produce the required volume.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

EMULSIO PARAFFINI LIQUIDI ET KAOLINI

(Emuls. Paraff. Liq. et Kaolin.)

Emulsion of Liquid Paraffin and Kaolin

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	250.0 ml.	5 fl. oz.
Acacia, in powder	34.3 g.	300 gr.
Tragacanth, in powder	4.3 g.	37½ gr.
Kaolin	187.5 g.	3¾ oz.
Chloroform Waterto 1000.0 ml.	to 20 fl. oz.

Triturate quickly the liquid paraffin with the acacia and tragacanth; without delay add 125 millilitres (2½ fluid ounces) of chloroform water and stir briskly until emulsified. Gradually add a suspension of the kaolin in 500 millilitres (10 fluid ounces) of chloroform water and sufficient chloroform water to produce the required volume.

Dose.—15 to 60 millilitres (½ to 2 fluid ounces).

ENEMATA

Enemas

Enemas are aqueous or oily solutions or suspensions intended for rectal injection. They are given for their anthelmintic, nutritive,

purgative, sedative, or stimulating effects, or for X-ray examination of the lower bowel. They should be freshly prepared and any solid substances or oils contained in them should be uniformly suspended. In the absence of specific instructions for preparing an enema the following strengths and quantities may be considered suitable for administration to adults:—

Enema Asafoetidae.—Tincture of asafoetida, from 6 to 12 per cent. v/v, in mucilage of starch. Dose.— 120 millilitres (4 fluid ounces).

Enema Bismuthi.—Bismuth carbonate or subchloride, from 10 to 30 per cent. w/v, in mucilage of starch. Dose.— 600 millilitres (20 fluid ounces).

Enema Chloralis Hydratis.—Chloral hydrate, 1 to 3 per cent. w/v, in mucilage of starch. Dose.— 120 millilitres (4 fluid ounces).

Enema Dextrosi.—Dextrose, 10 per cent. w/v, in water or peptonised milk. Dose.— 120 millilitres (4 fluid ounces).

Enema Glucosi Liquidi.—Liquid glucose, 10 per cent. w/v, in water or peptonised milk. Dose.— 120 millilitres (4 fluid ounces).

Enema Glycerini.—Glycerin, undiluted. Dose.— 4 to 16 millilitres (1 to 4 fluid drachms). Glycerin, 20 to 50 per cent. v/v, in water or mucilage of starch. Dose.— 15 to 60 millilitres ($\frac{1}{2}$ to 2 fluid ounces).

Enema Magnesii Sulphatis.—Magnesium sulphate, 5 per cent. w/v, in mucilage of starch, with 10 per cent. v/v of olive oil. Dose.— 600 millilitres (20 fluid ounces).

Enema Olei Olivæ.—Olive oil, undiluted. Dose.— 150 to 600 millilitres (5 to 20 fluid ounces). Olive oil, 20 per cent. v/v, in mucilage of starch. Dose.— 600 millilitres (20 fluid ounces).

Enema Olei Ricini.—Castor oil, 10 per cent. v/v, in a 5 per cent. w/v aqueous solution of soft soap. Dose.— 600 millilitres (20 fluid ounces).

Enema Opii.—Tincture of opium, 0.5 to 6 per cent. v/v, in mucilage of starch. Dose.— 60 to 120 millilitres (2 to 4 fluid ounces).

Enema Ovi.—1 or 2 yolks of egg in peptonised beef tea. Dose.— 120 millilitres (4 fluid ounces).

Enema Pancreatini.—Solution of pancreatin, 6.5 per cent. v/v, in equal parts of milk and beef tea. Dose.— 120 millilitres (4 fluid ounces).

Enema Paraldehydi.—Paraldehyde, 4 millilitres (60 minims) per stone body weight, with 5 per cent. w/v of dextrose, in normal saline.

Enema Potassii Bromidi.—Potassium bromide, 1 per cent. w/v, with acetylsalicylic acid, 0.5 per cent. w/v, and mucilage of tragacanth, in normal saline. Dose.— 150 millilitres (5 fluid ounces).

Enema Quassia.—Fresh infusion of quassia. Dose.— 600 millilitres (20 fluid ounces).

Enema Saponis.—Soft soap, 5 per cent. w/v, in water. Dose.— 600 millilitres (20 fluid ounces).

Enema Sodii Chloridi.—Sodium chloride, from 2·5 to 5 per cent. w/v, in mucilage of starch or in a 5 per cent. w/v aqueous solution of soft soap. Dose.— 600 millilitres (20 fluid ounces). Hypertonic.— Sodium chloride, 4 per cent. w/v, in water. Normal.—Sodium chloride, 0·9 per cent. w/v, in water.

Enema Terebinthinae.—Oil of turpentine, from 2·5 to 5 per cent. v/v, in mucilage of starch or in a 5 per cent. w/v aqueous solution of soft soap. Dose.— 600 millilitres (20 fluid ounces).

EXTRACTA

Extracts

Extracts are preparations containing the active principles of crude drugs with the minimum amount of inert matter, and are prepared by extraction with suitable solvents, such as water, alcohol, or ether. They may be of two general types—liquid extracts and solid extracts.

Liquid Extracts are usually of such a strength that one part by volume of the preparation is equivalent to one part by weight of the crude drug. If, however, the active principle is of a potent nature and permits of a chemical or biological assay, the liquid extract is then adjusted to a definite strength which represents the content of active principle of an average sample of the crude drug.

Solid Extracts vary in consistency according to the degree of concentration. Evaporation may be stopped when the extractive is of the nature of a soft mass (soft extract), or continued to dryness (dry extract).

Soft Extracts possess certain disadvantages. It is difficult to define what the exact consistency of a "soft" extract should be, and because of this, variations occur in the products. During storage, soft extracts generally tend to harden, forming tough masses which are difficult to handle on the dispensing counter. Moreover, when the active principle is of a potent nature and capable of being assayed, it is very difficult to find a suitable diluent with which to adjust the preparation to a standard strength. These factors tend to produce an appreciable variation in strength and, for this reason, soft extracts are being replaced gradually by dry extracts.

Dry Extracts are generally preferred to soft extracts because they are more readily handled in dispensing, less variable in strength,

and less liable to decomposition during storage. They are usually produced by evaporating the extractive to dryness under reduced pressure and, if the active principle is of a potent nature, assaying and adjusting to a standard by dilution with a substance such as lactose or calcium phosphate. The standard strengths set up for potent dry extracts bear no relation to the crude drug, but are determined by the dose, the strength being so adjusted that the maximum dose shall not be less than 0.06 gramme (1 grain). In order to obtain this, it may happen that the extract is actually weaker than the crude drug itself, as in the case of extract of strophanthus. Lactose forms an ideal diluent for dry extracts unless the dry extractive is deliquescent, when an absorbent diluent such as calcium phosphate is used and the preparation stored in well-closed containers. It is advisable to store all types of extracts in this manner and also to protect them from light.

EXTRACTUM AGROPYRI LIQUIDUM

(Ext. Agropyr. Liq.)

Liquid Extract of Couch Grass

Synonym—Liquid Extract of Triticum.

	<i>Metric</i>	<i>Imperial</i>
Couch Grass, cut small	1000 g.	20 oz.
Distilled Water	10000 ml.	200 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Boil the couch grass with the distilled water for thirty minutes and strain; evaporate to 750 millilitres (15 fluid ounces), cool, add sufficient of the alcohol to produce the required volume and filter.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

EXTRACTUM ALETRIDIS LIQUIDUM

(Ext. Aletr. Liq.)

Liquid Extract of Aletris

	<i>Metric</i>	<i>Imperial</i>
Aletris, in moderately fine powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the aletris with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 0.3 to 1 millilitre (5 to 15 minims).

EXTRACTUM ALOES

(Ext. Aloes)

Extract of Aloes

				<i>Metric</i>	<i>Imperial</i>
Aloes	1000 g.	16 oz.
Distilled Water		10000 ml.	160 fl. oz.

Add the aloes in small fragments to the boiling distilled water, stir well until thoroughly mixed and set the mixture aside for twenty-four hours; decant, strain, and evaporate the strained liquid to dryness at a temperature not exceeding 60°.

Dose.— 0·06 to 0·25 gramme (1 to 4 grains).

EXTRACTUM ANTHEMIDIS

(Ext. Anthem.)

Extract of Chamomile

				<i>Metric</i>	<i>Imperial</i>
Chamomile	1000 g.	16 oz.
Oil of Chamomile		2 ml.	15½ m.
Distilled Water	10000 ml.	160 fl. oz.

Boil the chamomile with the distilled water until the volume is reduced to one-half; strain, press the marc, filter, and evaporate the filtrate to the consistence of a soft extract, adding the oil of chamomile towards the end of the process.

Dose.— 0·12 to 0·5 gramme (2 to 8 grains).

EXTRACTUM ANTHEMIDIS LIQUIDUM

(Ext. Anthem. Liq.)

Liquid Extract of Chamomile

				<i>Metric</i>	<i>Imperial</i>
Chamomile, in moderately coarse powder	1000 g.	20 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the chamomile with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

EXTRACTUM APII LIQIDUM

(Ext. Apii Liq.)

Liquid Extract of Celery

	<i>Metric</i>	<i>Imperial</i>
Celery, in moderately fine powder	1000 g.	20 oz.
Alcohol (95 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the celery with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion, and add sufficient of the alcohol to produce the required volume. Allow to stand for four days and separate any excess of oil by decantation, or by filtration through a filter moistened with alcohol.

Dose.— 0·3 to 1·2 millilitres (5 to 20 minims).

EXTRACTUM AURANTII LIQIDUM

(Ext. Aurant. Liq.)

Liquid Extract of Orange

	<i>Metric</i>	<i>Imperial</i>
Dried Bitter-Orange Peel, cut small	1000 g.	20 oz.
Alcohol (70 per cent.)	1500 ml.	30 fl. oz.

Macerate the dried bitter-orange peel with 1000 millilitres (20 fluid ounces) of the alcohol in a covered vessel for five days, shaking occasionally, and press out the liquid. Add the remainder of the alcohol to the pressed marc, macerate for two days and press out the liquid. Mix the two liquids and filter.

Dose.— 0·6 to 1·2 millilitres (10 to 20 minims).

EXTRACTUM BELÆ LIQIDUM

(Ext. Belæ Liq.)

Liquid Extract of Bael

	<i>Metric</i>	<i>Imperial</i>
Bael	1000 g.	20 oz.
Chloroform Water	15000 ml.	300 fl. oz.
Chloroform	2 ml.	20 m.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Bruise the bael and macerate for twelve hours with 5000 millilitres (100 fluid ounces) of the chloroform water; pour off and reserve the clear liquid; repeat the maceration a second and a third time for one hour in each case, using for each maceration 5000 millilitres (100 fluid ounces) of the chloroform water; press the marc and strain the mixed

liquids through flannel. Evaporate to 750 millilitres (15 fluid ounces), cool, add the chloroform dissolved in sufficient alcohol (90 per cent.) to produce the required volume, and filter.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

EXTRACTUM BELLADONNÆ VIRIDE

(Ext. Bellad. Vir.)

Green Extract of Belladonna

	<i>Metric</i>	<i>Imperial</i>
Belladonna Leaf, in moderately coarse powder	1000 g.	16 oz.
Alcohol (70 per cent.)	a sufficient quantity	
Alcohol (25 per cent.)	a sufficient quantity	
Liquid Glucose	a sufficient quantity	

Moisten the belladonna leaf with 750 millilitres (12 fluid ounces) of alcohol (70 per cent.), pack in a percolator and allow percolation to proceed, using alcohol (70 per cent.) as menstruum, until 2000 millilitres (32 fluid ounces) of percolate has been collected. Continue percolation with alcohol (25 per cent.) until the drug is exhausted. Evaporate the mixed percolates to the consistence of a soft extract and determine the proportion of alkaloid in the product. Dilute the remainder of the product with liquid glucose, or continue evaporation, in order to produce an extract of the required strength.

Standard.—Green extract of belladonna, determined by the method of the British Pharmacopœia for *Extractum Belladonnæ Siccum*, contains not less than 0.95 per cent. and not more than 1.05 per cent. of the alkaloids of belladonna calculated as hyoscyamine.

Dose.— 0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

In making this preparation the alcohols may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strengths, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

Green extract of belladonna replaces the unstandardised Extractum Belladonnæ Viride, B.P. 1898.

EXTRACTUM BUCHU LIQIDUM

(Ext. Buchu Liq.)

Liquid Extract of Buchu

	<i>Metric</i>	<i>Imperial</i>
Buchu, in moderately fine powder	1000 g.	20 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Pack the buchu in a percolator, saturate it with alcohol, allow to stand for forty-eight hours, and then percolate until exhausted. Reserve the first 850 millilitres (17 fluid ounces) of percolate, evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

EXTRACTUM CANNABIS

(Ext. Cannab.)

Extract of Cannabis

	<i>Metric</i>	<i>Imperial</i>
Cannabis, in coarse powder	1000 g.	16 oz.
Alcohol (90 per cent.)	a sufficient quantity	

Exhaust the cannabis by percolation with the alcohol and evaporate to a soft extract.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

This extract replaces the Extractum Cannabis Indicæ of the British Pharmacopæia, 1914, which was prepared in the same way from Indian cannabis (Cannabis Indica).

EXTRACTUM CAULOPHYLLI LIQUIDUM

(Ext. Cauloph. Liq.)

Liquid Extract of Caulophyllum

Synonym—Liquid Extract of Blue Cohosh.

	<i>Metric</i>	<i>Imperial</i>
Caulophyllum, in moderately fine powder	1000 g.	20 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the caulophyllum with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0.6 to 2 millilitres (10 to 30 minims).

EXTRACTUM CEREI LIQUIDUM

(Ext. Cerei Liq.)

Liquid Extract of Cereus*Synonym*—Extractum Cacti Grandiflori Liquidum.

	<i>Metric</i>	<i>Imperial</i>
Cereus, in moderately fine powder	1000 g.	20 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Pack the cereus in a percolator, saturate it with alcohol, allow to stand for forty-eight hours, and then percolate until exhausted. Reserve the first 850 millilitres (17 fluid ounces) of percolate, evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0·06 to 0·6 millilitre (1 to 10 minims).

EXTRACTUM COCÆ LIQUIDUM

(Ext. Cocæ Liq.)

Liquid Extract of Coca*Synonym*—Miscible Liquid Extract of Coca.

	<i>Metric</i>	<i>Imperial</i>
Coca, in moderately coarse powder	1000 g.	20 oz.
Alcohol (60 per cent.)	a sufficient quantity	

Exhaust the coca with the alcohol by percolation. Evaporate the percolate at a temperature not exceeding 80° until the volume is reduced to 500 millilitres (10 fluid ounces). Pour off from the residue as much of the clear liquid as possible, wash the residue with 100 millilitres (2 fluid ounces) of distilled water, mix the washings with the clear liquid and determine the proportion of alkaloid in the product. Evaporate further or dilute the product with more of the alcohol so as to produce a liquid extract of the required strength.

Standard.—Liquid extract of coca contains not less than 0·45 per cent. and not more than 0·55 per cent. w/v of ether-soluble alkaloids, calculated as cocaine.

Assay.—Shake 10 millilitres with 2 millilitres of dilute solution of ammonia and 25 millilitres of ether. Separate and shake the aqueous layer with 20 millilitres followed by 10 millilitres of ether. Extract the mixed ethereal solutions with a mixture of 5 millilitres of water and 5 millilitres of N/1 sulphuric acid followed by a mixture of 9 millilitres of water and 1 millilitre of N/1 sulphuric acid. To the combined acid liquids add 20 millilitres of ether and make just alkaline with dilute solution of ammonia. Separate the aqueous layer and extract it with two successive quantities of 15 millilitres of ether. Distil off the ether and dissolve the residue in 10 millilitres of N/10 sulphuric acid. Titrate the solution with N/10 sodium hydroxide using methyl red as indicator; each millilitre of N/10 sulphuric acid is equivalent to 0·0303 gramme of ether-soluble alkaloids, calculated as cocaine.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM COLCHICI ACETICUM

(Ext. Colch. Acet.)

Acetic Extract of Colchicum

	<i>Metric</i>	<i>Imperial</i>
Colchicum Corm, fresh	950 g.	9½ oz.
Acetic Acid	50 ml.	½ fl. oz.

Crush the corm, add the acetic acid, and press out the juice; allow the feculence to subside, and heat the clear liquid to 100°; strain through flannel and evaporate to a soft extract.

Dose.—0·03 to 0·12 gramme (½ to 2 grains).

Acetic extract of colchicum is an unstandardised extract and its use should, where possible, be discontinued in favour of *Extractum Colchici Siccum*.

EXTRACTUM CONII

(Ext. Conii)

Extract of Conium*Synonym*—Extract of Hemlock.

	<i>Metric</i>	<i>Imperial</i>
Conium Leaf	1000 g.	16 oz.

Bruise the conium leaf in a stone mortar, press out the juice, heat it gradually to 55°, and separate the green colouring matter by means of a calico filter. Heat the strained liquid to 95° and again filter. Evaporate the filtrate on a water-bath to a thin syrup; then add to it the green colouring matter previously separated and passed through a hair sieve and, mixing thoroughly, continue the evaporation at a temperature not exceeding 60° to a soft extract.

Dose.—0·12 to 0·4 gramme (2 to 6 grains).

EXTRACTUM CONVALLARIÆ LIQUIDUM

(Ext. Convallar. Liq.)

Liquid Extract of Convallaria

	<i>Metric</i>	<i>Imperial</i>
Convallaria, in moderately fine powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the convallaria with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0·3 to 0·6 millilitre (5 to 10 minims).

EXTRACTUM COTO LIQUIDUM

(Ext. Coto Liq.)

Liquid Extract of Coto

	<i>Metric</i>	<i>Imperial</i>
Coto, in moderately fine powder	1000 g.	20 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the coto with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

EXTRACTUM CUBEBAE LIQUIDUM

(Ext. Cubeb. Liq.)

Liquid Extract of Cubeb

	<i>Metric</i>	<i>Imperial</i>
Cubeb, in moderately coarse powder	1000 g.	20 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the cubeb with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM DAMIANÆ

(Ext. Damian.)

Extract of Damiana

	<i>Metric</i>	<i>Imperial</i>
Damiana, in moderately fine powder	1000 g.	16 oz.
Alcohol (60 per cent.)	a sufficient quantity	
Distilled Water	a sufficient quantity	

Mix the damiana with 2500 millilitres (40 fluid ounces) of the alcohol and macerate in a closed vessel for forty-eight hours; then transfer to a percolator, and when the liquid ceases to pass, continue the percolation, using distilled water, until 2500 millilitres (40 fluid ounces) of liquid has been collected. Evaporate the percolate to a soft extract.

Dose.— 0·3 to 0·6 gramme (5 to 10 grains).

In making this preparation the alcohol (60 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM DAMIANÆ LIQUIDUM

(Ext. Damian. Liq.)

Liquid Extract of Damiana

	<i>Metric</i>	<i>Imperial</i>
Damiana, in moderately fine powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the damiana with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM EPHEDRÆ LIQUIDUM

(Ext. Ephed. Liq.)

Liquid Extract of Ephedra

	<i>Metric</i>	<i>Imperial</i>
Ephedra, in moderately coarse powder	1000 g.	20 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the ephedra with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Evaporate the remainder of the percolate, under reduced pressure at a temperature not exceeding 40°, to a syrupy consistence, dissolve it in the reserved portion, and add sufficient of the alcohol to produce the required volume.

• **Dose.**— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

EXTRACTUM ERGOTÆ

(Ext. Ergot.)

Extract of Ergot

	<i>Metric</i>	<i>Imperial</i>
Ergot, in moderately fine powder	1000 g.	16 oz.
Sulphuric Acid	a sufficient quantity	
Alcohol (50 per cent.)	a sufficient quantity	
Liquid Glucose	a sufficient quantity	

Percolate the ergot with light petroleum (boiling-point, 40° to 50°) until 1 millilitre of the percolate leaves not more than a barely perceptible film when evaporated in a glass basin. Dry the powder by exposure to air, completing the drying if necessary in a current of air at a temperature not exceeding 40°. Again reduce it to powder, moisten it with a sufficient quantity of a mixture of 4 volumes of sulphuric acid

and 1000 volumes of alcohol (50 per cent.) to render it evenly damp and set aside in a tightly closed container for four hours. Place in a percolator, add a sufficient quantity of the acidified alcohol to saturate the drug and leave a layer of liquid above, and, when the liquid commences to drop from the percolator, close the outlet and macerate for forty-eight hours. Then allow percolation to proceed slowly, using as menstruum a mixture of sulphuric acid and alcohol (50 per cent.) in the same proportions as before and continuing the percolation until 6000 millilitres of percolate has been collected. Add to the percolate a slight excess of calcium carbonate, stir well and allow to stand with occasional stirring until effervescence ceases. Filter and evaporate the filtrate as rapidly as possible under reduced pressure at a temperature not exceeding 40° to a soft extract. Determine the proportion of alkaloid in the product and add sufficient liquid glucose to produce an extract of the required strength.

It should be **stored** in well-closed containers in a cool place.

Standard.—Extract of ergot, determined by the method of the British Pharmacopœia for *Extractum Ergotæ Liquidum*, using about 1 gramme, accurately weighed, dissolved in 10 millilitres of alcohol (50 per cent.), contains when freshly prepared 0·5 per cent. of total alkaloids calculated as ergotoxine.

Dose.—0·06 to 0·2 gramme (1 to 3 grains).

In making this preparation the alcohol (50 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM EUONYMI

(*Ext. Euonym.*)

Extract of Euonymus

Synonyms—Euonymin; Brown Euonymin.

	<i>Metric</i>	<i>Imperial</i>
Euonymus, in coarse powder ..	1000 g.	16 oz.
Calcium Phosphate	a sufficient quantity	
Alcohol (45 per cent.)	a sufficient quantity	

Exhaust the euonymus with the alcohol by percolation, evaporate the percolate and thoroughly dry the residue. Powder the product as far as possible and mix it with one-fourth of its weight of calcium phosphate, continuing the drying and powdering until a sufficiently dry preparation is obtained.

It should be **stored** in well-closed containers.

Dose.—0·06 to 0·12 gramme (1 to 2 grains).

In making this preparation the alcohol (45 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM EUPHORBIAE LIQUIDUM**(Ext. Euphorb. Liq.)****Liquid Extract of Euphorbia***Synonym*—Extractum Euphorbiae Piluliferæ Liquidum.

	<i>Metric</i>	<i>Imperial</i>
Euphorbia, in moderately coarse powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the euphorbia with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

EXTRACTUM FUCI**(Ext. Fuci)****Extract of Bladderwrack**

	<i>Metric</i>	<i>Imperial</i>
Bladderwrack, dried, in moderately coarse powder	1000 g.	16 oz.
Alcohol (45 per cent.)	a sufficient quantity	

Exhaust the bladderwrack with the alcohol by percolation and evaporate the percolate to a soft extract.

Dose.—0.2 to 0.6 gramme (3 to 10 grains).

• In making this preparation the alcohol (45 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM FUCI LIQUIDUM**(Ext. Fuci Liq.)****Liquid Extract of Bladderwrack**

	<i>Metric</i>	<i>Imperial</i>
Bladderwrack, dried, in moderately coarse powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the bladderwrack with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

EXTRACTUM GELSEMI

(Ext. Gelsem.)

Extract of Gelsemium

	<i>Metric</i>	<i>Imperial</i>
Gelsemium, in moderately		
fine powder	1000 g.	16 oz.
Alcohol (90 per cent.)	a sufficient quantity	
Distilled Water	a sufficient quantity	

Mix the gelsemium with 2500 millilitres (40 fluid ounces) of the alcohol and macerate in a closed vessel for forty-eight hours; then transfer to a percolator and, when the liquid ceases to pass, continue the percolation with distilled water until 2500 millilitres (40 fluid ounces) of percolate has been collected. Evaporate the percolate to a soft extract.

Dose.— 0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM GOSSYPII CORTICIS LIQUIDUM

(Ext. Gossyp. Cort. Liq.)

Liquid Extract of Cotton Root Bark

	<i>Metric</i>	<i>Imperial</i>
Cotton Root Bark, in moderately		
coarse powder	1000 g.	20 oz.
Glycerin	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the glycerin with 750 millilitres (15 fluid ounces) of the alcohol; moisten the cotton root bark with a sufficient quantity of this mixture, and percolate, using as menstruum first the remainder of the mixture of glycerin and alcohol, and afterwards sufficient of the alcohol to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM GRINDELIAE LIQUIDUM

(Ext. Grindel. Liq.)

Liquid Extract of Grindelia

	<i>Metric</i>	<i>Imperial</i>
Grindelia, in moderately fine		
powder	1000 g.	20 oz.
Sodium Bicarbonate	100 g.	2 oz.
Distilled Water	500 ml.	10 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the grindelia with the alcohol by percolation. Recover the alcohol from the percolate by distillation and dissolve the residue in the distilled water to which the sodium bicarbonate has previously been added; after effervescence has ceased, add sufficient distilled water to produce 750 millilitres (15 fluid ounces), and then sufficient of the alcohol to produce the required volume.

Dose.—0.6 to 1.2 millilitres (10 to 20 minims).

In making this preparation the alcohol (90 per cent.) used for the percolation may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM HÆMATOXYLI LIQUIDUM

(Ext. Hæmatox. Liq.)

Liquid Extract of Logwood

Synonym—Liquid Extract of Hæmatoxyton.

	<i>Metric</i>	<i>Imperial</i>
Logwood, in moderately coarse powder	1000 g.	20 oz.
Alcohol (90 per cent.)	150 ml.	3 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Boil the logwood with 2000 millilitres (40 fluid ounces) of the water for thirty minutes and strain. Repeat the process twice, mix the strained liquids and evaporate to 850 millilitres (17 fluid ounces). Add the alcohol, set aside for seven days, decant the clear liquid and add sufficient distilled water to produce the required volume.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

EXTRACTUM HAMAMELIDIS

(Ext. Hamam.)

Extract of Hamamelis

Synonyms—Hamamelin; Hamamelidin.

	<i>Metric</i>	<i>Imperial</i>
Hamamelis, in moderately fine powder	1000 g.	16 oz.
Alcohol (90 per cent.)	a sufficient quantity	

Exhaust the hamamelis with the alcohol by percolation, evaporate the percolate to dryness at a low temperature and reduce it to fine powder. It should be **stored** in well-closed containers.

Dose.—0.06 to 0.3 gramme (1 to 5 grains).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM HYDRASTIS

(Ext. Hydrast.)

Extract of Hydrastis*Synonyms*—Hydrastin; Extractum Hydrastis Siccum.

	<i>Metric</i>	<i>Imperial</i>
Hydrastis, in moderately fine powder	1000 g.	16 oz.
Alcohol (70 per cent.)	a sufficient quantity	

Exhaust the hydrastis with the alcohol by percolation and evaporate the percolate to dryness. Determine the proportion of hydrastine in the residue and mix the remainder of the product with sufficient calcium phosphate to produce an extract of the required strength.

It should be **stored** in well-closed containers.

Standard.—Extract of hydrastis contains not less than 7·5 per cent. and not more than 8·5 per cent. of hydrastine.

Assay.—Mix 2 grammes with 10 millilitres of alcohol (70 per cent.) and proceed as described under Extractum Hydrastis Liquidum. The weight obtained is that of the hydrastine in 1 gramme of the extract examined.

Dose.—0·03 to 0·12 gramme ($\frac{1}{2}$ to 2 grains).

In making this preparation the alcohol (70 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM HYDRASTIS LIQIDUM

(Ext. Hydrast. Liq.)

Liquid Extract of Hydrastis*Synonym*—Extractum Hydrastidis fluidum, I.A.

	<i>Metric</i>	<i>Imperial</i>
Hydrastis, in moderately fine powder	1000 g.	20 oz.
Alcohol (60 per cent.)	a sufficient quantity	

Exhaust the hydrastis with the alcohol by percolation, reserving the first 800 millilitres (16 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and determine the proportion of hydrastine in the liquid extract thus obtained. To the remainder of the liquid extract add sufficient of the alcohol to produce a liquid extract of the required strength.

Standard.—Liquid extract of hydrastis contains not less than 1·9 per cent. and not more than 2·1 per cent. w/v of hydrastine.

Assay.—Transfer 10 millilitres to a 100 millilitre graduated flask, add 20 millilitres of potassium iodide solution diluted with 60 millilitres of water, and sufficient water to produce 100 millilitres. Shake the mixture for several minutes and filter. Transfer 50 millilitres of the filtrate to a separator, render alkaline with solution of ammonia, add 30 millilitres of ether and shake at intervals during several minutes. Allow the liquid to separate, draw off the aqueous layer and repeat the operation with two successive portions each of 20 millilitres of ether for one minute. Evaporate the mixed ethereal solutions at a gentle heat in a tared beaker, dry the residue on a water-bath and weigh. The weight obtained is that of the hydrastine in 5 millilitres of the liquid examined.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

EXTRACTUM IRIDIS

(Ext. Irid.)

Extract of Iris

Synonyms—Iridin; Extractum Iridis Siccum.

	<i>Metric</i>	<i>Imperial</i>
Iris, in moderately fine powder ..	1000 g.	16 oz.
Calcium Phosphate	a sufficient quantity	
Alcohol (70 per cent.)	a sufficient quantity	

Exhaust the iris with the alcohol by percolation, and evaporate the percolate to dryness. Reduce the residue to fine powder, add one-twentieth of its weight of calcium phosphate, again dry and powder.

It should be **stored** in well-stoppered bottles.

Dose.—0.06 to 0.2 gramme (1 to 3 grains).

In making this preparation the alcohol (70 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM JABORANDI LIQUIDUM

(Ext. Jaborand. Liq.)

Liquid Extract of Jaborandi

	<i>Metric</i>	<i>Imperial</i>
Jaborandi, in moderately coarse powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the jaborandi with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate and continuing until a further 2250 millilitres (45 fluid ounces) has been collected. Evaporate the latter to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

EXTRACTUM KAVÆ LIQUIDUM

(Ext. Kavæ Liq.)

Liquid Extract of Kava

	<i>Metric</i>	<i>Imperial</i>
Kava, in moderately coarse powder	1000 g.	20 oz.
Alcohol (45 per cent.)	a sufficient quantity	
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the kava with 2000 millilitres (40 fluid ounces) of the alcohol (90 per cent.), set aside in a closed vessel for forty-eight hours, transfer to a percolator and percolate slowly, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue the percolation, adding the alcohol (45 per cent.), until the powder is exhausted; evaporate this percolate at a temperature below 80° to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol (90 per cent.) to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM KINO EUCALYPTI LIQUIDUM

(Ext. Kino Eucalypt. Liq.)

Liquid Extract of Eucalyptus Kino

Synonyms—Extractum Gummi Rubri Liquidum; Liquid Extract of Red Gum.

	<i>Metric</i>	<i>Imperial</i>
Eucalyptus Kino	250 g.	5 oz.
Alcohol (90 per cent.)	100 ml.	2 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the eucalyptus kino in 650 millilitres (13 fluid ounces) of the distilled water, strain, add the alcohol and sufficient distilled water to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

EXTRACTUM KOLÆ LIQUIDUM

(Ext. Kolæ Liq.)

Liquid Extract of Kola

	<i>Metric</i>	<i>Imperial</i>
Kola, in moderately fine powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the kola with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 0·6 to 1·2 millilitres (10 to 20 minims).

EXTRACTUM LACTUCÆ

(Ext. Lactuc.)

Extract of Lettuce

	<i>Metric</i>	<i>Imperial</i>
Lettuce	1000 g.	16 oz.

Bruise the lettuce in a stone mortar, press out the juice, heat it gradually to 55° and separate the green colouring matter by a calico filter. Heat the strained liquid to 95° and again filter. Evaporate the filtrate on a water-bath to the consistence of a thin syrup; add to it the green colouring matter previously separated and passed through a hair sieve and, mixing thoroughly, continue the evaporation at a temperature not exceeding 60° to a soft extract.

Dose.— 0.3 to 1 gramme (5 to 15 grains).

EXTRACTUM LEPTANDRÆ

(Ext. Leptand.)

Extract of Leptandra*Synonym*—Leptandrin.

	<i>Metric</i>	<i>Imperial</i>
Leptandra, in moderately coarse powder	1000 g.	16 oz.
Calcium Phosphate	a sufficient quantity	
Alcohol (90 per cent.	a sufficient quantity	

Exhaust the leptandra with the alcohol by percolation, evaporate the percolate to dryness at a low temperature, reduce it to fine powder and mix with one-twentieth of its weight of calcium phosphate.

Dose.— 0.03 to 0.12 gramme ($\frac{1}{2}$ to 2 grains).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM LUPULI

(Ext. Lupul.)

Extract of Lupulus*Synonym*—Extract of Hops.

	<i>Metric</i>	<i>Imperial</i>
Lupulus	1000 g.	16 oz.
Alcohol (90 per cent.)	1875 ml.	30 fl. oz.
Distilled Water	10000 ml.	160 fl. oz.

Macerate the lupulus in the alcohol for seven days; press, filter and

evaporate to a soft extract; boil the residual lupulus with the water for one hour, press, strain and evaporate to a soft extract; mix the two extracts.

Dose.— 0.3 to 1 gramme (5 to 15 grains).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM MALTI CUM OLEO OLIVÆ

(Ext. Malt. c. Ol. Oliv.)

Extract of Malt with Olive Oil

			<i>Metric</i>	<i>Imperial</i>
Olive Oil	100 g.	1 oz. 262½ gr.
Extract of Malt	to 1000 g.	to 16 oz.

Mix.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

EXTRACTUM MALTI CUM VITAMINIS

(Ext. Malt. c. Vitam.)

Extract of Malt with Vitamins

Extract of malt with vitamins contains in each fluid drachm approximately 3000 units of vitamin A and approximately 225 units of vitamin D. It may be prepared with standardised cod-liver oil concentrate suitably adjusted, if necessary, or by the following process:—

			<i>Metric</i>	<i>Imperial</i>
Solution of Vitamin A	10 g.	70 gr.
Solution of Irradiated Ergosterol			15 g.	105 gr.
Arachis Oil	30 g.	210 gr.
Vanillin	1 g.	7 gr.
Extract of Malt	to 1000 g.	to 16 oz.

Mix the solutions of vitamin A and irradiated ergosterol and the vanillin with the arachis oil, and rapidly incorporate with the extract of malt in a warm mortar.

It should be **stored** in completely-filled, well-closed containers in a cool place and protected from light.

Dose.— 8 to 30 millilitres (¼ to 1 fluid ounce).

EXTRACTUM MALTI FERRATUM

(Ext. Malt. Ferrat.)

Ferrated Extract of Malt

	<i>Metric</i>	<i>Imperial</i>
Soluble Iron Pyrophosphate ..	15 g.	105 gr.
Distilled Water	25 ml.	192 m.
Extract of Maltto 1000 g.	to 16 oz.

Dissolve the iron pyrophosphate in the distilled water and mix with the extract of malt in a warm vessel.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM

(Ext. Malt. Liq.)

Liquid Extract of Malt

Liquid extract of malt is prepared from malted barley by digestion with water and by evaporation of the strained liquid until the product, after the addition of the necessary proportion of alcohol, has a specific gravity of about 1·23, or by the following process.

	<i>Metric</i>	<i>Imperial</i>
Extract of Malt	675 ml.	13½ fl. oz.
Alcohol (90 per cent.) ..	100 ml.	2 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Mix the alcohol with 250 millilitres (5 fluid ounces) of the water, dilute the extract of malt with the mixture and add sufficient distilled water to produce 1000 millilitres (20 fluid ounces). Allow to stand until clear, or clarify by filtration if necessary.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM CUM GLYCEROPHOSPHATIBUS

(Ext. Malt. Liq. c. Glycerophosph.)

Liquid Extract of Malt with Glycerophosphates

	<i>Metric</i>	<i>Imperial</i>
Solution of Potassium Glycero-phosphate	18·3 g.	160 gr.
Solution of Sodium Glycero-phosphate	18·3 g.	160 gr.
Liquid Extract of Maltto 1000·0 ml.	to 20 fl. oz.

Mix.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM CUM HÆMOGLOBINO

(Ext. Malt. Liq. c. Hæmoglob.)

Liquid Extract of Malt with Hæmoglobin*Synonym*—Malt and Hæmoglobin.

	<i>Metric</i>	<i>Imperial</i>
Hæmoglobin	125 g.	2½ oz.
Glycerin	100 ml.	2 fl. oz.
Liquid Extract of Malt	to 1000 ml.	to 20 fl. oz.

Triturate the hæmoglobin with the glycerin and about 750 millilitres (15 fluid ounces) of the liquid extract of malt and allow the mixture to stand, with occasional stirring, until the hæmoglobin is dissolved. Add sufficient liquid extract of malt to produce the required volume and strain through muslin if necessary.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM CUM HYPOPHOSPHITIBUS

(Ext. Malt. Liq. c. Hypophosph.)

Liquid Extract of Malt with Hypophosphites

	<i>Metric</i>	<i>Imperial</i>
Calcium Hypophosphite .. .	5 g.	43¾ gr.
Sodium Hypophosphite .. .	5 g.	43¾ gr.
Distilled Water	50 ml.	1 fl. oz.
Liquid Extract of Malt	to 1000 ml.	to 20 fl. oz.

Dissolve the hypophosphites in the distilled water and mix with the liquid extract of malt.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM CUM QUININA ET STRYCHNINA

(Ext. Malt. Liq. c. Quinin. et. Strych.)

Liquid Extract of Malt with Quinine and Strychnine

	<i>Metric</i>	<i>Imperial</i>
Quinine Hydrochloride .. .	2·3 g.	20 gr.
Solution of Strychnine Hydrochloride	10·0 ml.	96 m.
Distilled Water	50·0 ml.	1 fl. oz.
Liquid Extract of Malt	to 1000·0 ml.	to 20 fl. oz.

Dissolve the quinine hydrochloride in the distilled water with the aid of gentle heat, add the solution of strychnine hydrochloride and sufficient liquid extract of malt to produce the required volume.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

EXTRACTUM MALTI LIQUIDUM ET MEDULLÆ RUBRÆ

(Ext. Malt. Liq. et Medull. Rub.)

Liquid Extract of Malt and Red Bone Marrow

	<i>Metric</i>	<i>Imperial</i>
Extract of Red Bone Marrow ..	500 ml.	10 fl. oz.
Liquid Extract of Malt	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).**EXTRACTUM MEDULLÆ RUBRÆ**

(Ext. Medull. Rub.)

Extract of Red Bone Marrow*Synonym*—Glycerin Extract of Red Bone Marrow.

	<i>Metric</i>	<i>Imperial</i>
Red Bone Marrow	250 g.	5 oz.
Chloroform Water	a sufficient quantity	
Glycerin	a sufficient quantity	

Mix the red bone marrow with 500 millilitres (10 fluid ounces) of glycerin by vigorous trituration, add 500 millilitres (10 fluid ounces) of chloroform water and beat the whole together frequently during one hour; strain and add sufficient of a mixture of equal volumes of chloroform water and glycerin to produce 1000 millilitres (20 fluid ounces).

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).**EXTRACTUM OPII LIQUIDUM**

(Ext. Opii Liq.)

Liquid Extract of Opium

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Opium	37·5 g.	$\frac{3}{4}$ oz.
Alcohol (90 per cent.)	200·0 ml.	4 fl. oz.
Distilled Water	to 1000·0 ml.	to 20 fl. oz.

Mix the extract with 700 millilitres (14 fluid ounces) of distilled water and set aside in a cool place for twenty-four hours, stirring frequently; add the alcohol and again set aside for twenty-four hours; filter and wash the filter with sufficient distilled water to produce the required volume.

Standard.—Liquid extract of opium, determined by the method of the British Pharmacopœia for Tinctura Opii, contains not less

than 0·7 per cent. and not more than 0·8 per cent. w/v of morphine, calculated as anhydrous.

Dose.— 0·3 to 2 millilitres (5 to 30 minims).

EXTRACTUM PAPAVERIS LIQUIDUM

(Ext. Papav. Liq.)

Liquid Extract of Poppy

Synonym—Liquor pro Syrupo Papaveris.

	<i>Metric</i>	<i>Imperial</i>
Poppy Capsule, in moderately coarse powder	1000 g.	20 oz.
Alcohol (90 per cent.)	a sufficient quantity	
Alcohol (25 per cent.)	a sufficient quantity	
Distilled Water	a sufficient quantity	

Exhaust the poppy capsule by percolation with boiling distilled water and evaporate the percolate to about 700 millilitres (14 fluid ounces). Filter, and determine the proportion of morphine in the filtrate. Add to the remainder of the filtrate one-third its volume of alcohol (90 per cent.) and sufficient alcohol (25 per cent.) to produce a liquid extract of poppy of the required strength. Allow to stand for not less than seven days, and filter.

Standard.—Liquid extract of poppy, determined by the method of the British Pharmacopœia for Tinctura Opii Camphorata, using 2·5 millilitres, contains not less than 0·16 per cent. and not more than 0·18 per cent. w/v of morphine, calculated as anhydrous.

Dose.— 0·6 to 2 millilitres (10 to 30 minims).

EXTRACTUM PINI ALBI LIQUIDUM

(Ext. Pini Alb. Liq.)

Liquid Extract of White Pine

	<i>Metric</i>	<i>Imperial</i>
White Pine, in moderately fine powder	1000 g.	20 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the white pine with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate; evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

EXTRACTUM PINI CANADENSIS LIQUIDUM

(Ext. Pini Canad. Liq.)

Liquid Extract of Hemlock Spruce

	<i>Metric</i>	<i>Imperial</i>
Hemlock Spruce, in moderately fine powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the hemlock spruce with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

EXTRACTUM PISCIDIÆ LIQUIDUM

(Ext. Piscid. Liq.)

Liquid Extract of Piscidia

	<i>Metric</i>	<i>Imperial</i>
Piscidia, in moderately coarse powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the piscidia with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

EXTRACTUM PULSATILLÆ LIQUIDUM

(Ext. Pulsat. Liq.)

Liquid Extract of Pulsatilla

	<i>Metric</i>	<i>Imperial</i>
Pulsatilla, in moderately fine powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the pulsatilla with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.— 0·12 to 0·3 millilitre (2 to 5 minims).

EXTRACTUM QUASSIÆ

(Ext. Quass.)

Extract of Quassia

	<i>Metric</i>	<i>Imperial</i>
Quassia, rasped	100 g.	16 oz.
Distilled Water	a sufficient quantity	

Macerate the quassia with 500 millilitres (8 fluid ounces) of distilled water for twelve hours, transfer to a percolator and exhaust the drug by percolation with distilled water. Evaporate the percolate, filter before it becomes too thick, and evaporate to a soft extract.

Dose.— 0·18 to 0·3 gramme (3 to 5 grains).

EXTRACTUM QUILLAÏÆ LIQUIDUM

(Ext. Quill. Liq.)

Liquid Extract of Quillaia

	<i>Metric</i>	<i>Imperial</i>
Quillaia, in moderately fine powder	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the quillaia with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

EXTRACTUM RHEI

(Ext. Rhei)

Extract of Rhubarb

	<i>Metric</i>	<i>Imperial</i>
Rhubarb, in moderately coarse powder	1000 g.	16 oz.
Alcohol (60 per cent.)	a sufficient quantity	

Exhaust the rhubarb with the alcohol by percolation and evaporate the percolate to dryness.

It should be **stored** in well-closed containers.

Dose.— 0·12 to 0·5 gramme (2 to 8 grains).

In making this preparation the alcohol (60 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM RHEI LIQUIDUM

(Ext. Rhei Liq.)

Liquid Extract of Rhubarb

	<i>Metric</i>	<i>Imperial</i>
Rhubarb, in moderately coarse powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the rhubarb with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

EXTRACTUM SABAL LIQUIDUM

(Ext. Sabal Liq.)

Liquid Extract of Sabal

Synonym—Liquid Extract of Saw Palmetto.

	<i>Metric</i>	<i>Imperial</i>
Sabal, in moderately fine powder	1000 g.	20 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the sabal with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—0·6 to 1·5 millilitres (10 to 25 minims).

EXTRACTUM SALICIS NIGRÆ LIQUIDUM

(Ext. Salic. Nig. Liq.)

Liquid Extract of Black Willow

	<i>Metric</i>	<i>Imperial</i>
Black Willow, in moderately coarse powder	1000 g.	20 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the black willow with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

EXTRACTUM SCILLÆ LIQIDUM

(Ext. Scill. Liq.)

Liquid Extract of Squill

	<i>Metric</i>	<i>Imperial</i>
Squill, in coarse powder ..	1000 g.	20 oz.
Alcohol (70 per cent.) ..	to 1000 ml.	to 20 fl. oz.

Exhaust the squill with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion, add sufficient of the alcohol to produce the required volume and filter.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

EXTRACTUM STRAMONII

(Ext. Stramon.)

Extract of Stramonium

	<i>Metric</i>	<i>Imperial</i>
Stramonium, in moderately coarse powder	1000 g.	16 oz.
Alcohol (70 per cent.)	a sufficient quantity	
Liquid Glucose	a sufficient quantity	

Exhaust the stramonium with the alcohol by percolation and evaporate the percolate at a temperature not exceeding 80° to a soft extract. Determine the proportion of alkaloid in the product and, if necessary, evaporate further or add sufficient liquid glucose to produce an extract of the required strength.

Standard.—Extract of stramonium, determined by the method of the British Pharmacopœia for Extractum Belladonnæ Siccum, contains not less than 0·95 per cent. and not more than 1·05 per cent. of the alkaloids of stramonium calculated as hyoscyamine.

Dose.—0·016 to 0·06 gramme ($\frac{1}{4}$ to 1 grain.)

In making this preparation the alcohol (70 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM STRAMONII LIQIDUM

(Ext. Stramon. Liq.)

Liquid Extract of Stramonium

	<i>Metric</i>	<i>Imperial</i>
Stramonium, in moderately coarse powder	1000 g.	20 oz.
Alcohol (70 per cent.)	a sufficient quantity	

Exhaust the stramonium with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract and dissolve it in the reserved portion. Determine the proportion of alkaloid in the liquid and, if necessary, add more of the alcohol or continue evaporation to produce a liquid extract of the required strength.

Standard.—Liquid extract of stramonium, determined by the method of the British Pharmacopœia for *Extractum Belladonnæ Liquidum*, contains not less than 0.225 per cent. and not more than 0.275 per cent. w/v of the alkaloids of stramonium calculated as hyoscyamine.

Dose.—0.03 to 0.2 millilitre ($\frac{1}{2}$ to 3 minims).

EXTRACTUM STROPHANTHI

(Ext. *Strophanth.*)

Extract of *Strophanthus*

			<i>Metric</i>	<i>Imperial</i>
Strophanthus, in	moderately			
coarse powder	500 g.	8 oz.	
Ether	a sufficient quantity		
Alcohol (90 per cent.)	a sufficient quantity		
Lactose	to 1000 g.	to 16 oz.	

Pack the *strophanthus* in a percolator, moisten with ether and macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of ether until the liquid which passes through is colourless. Remove the marc from the percolator and dry it, gradually heating it to 50°. Again reduce it to powder, repack in a percolator, moisten with the alcohol and macerate for forty-eight hours. Then percolate slowly with more of the alcohol until 5000 millilitres (80 fluid ounces) of liquid is obtained. Evaporate most of the alcohol, transfer the residual liquid to a tared dish, concentrate until the liquid begins to thicken and add sufficient lactose to produce the required weight of powdered extract.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

This extract is unstandardised and represents half its weight of strophanthus. If desired it may be standardised by a biological method similar to the biological assay of tincture of strophanthus.

EXTRACTUM TARAXACI

(Ext. Tarax.)

Extract of Taraxacum

	<i>Metric</i>	<i>Imperial</i>
Taraxacum, fresh	1000 g.	16 oz.

Crush the taraxacum, press out the juice and allow the feculence to subside; decant, heat the liquid to 100° and maintain at that temperature for ten minutes, strain and evaporate to a soft extract.

Dose.— 0·3 to 1 gramme (5 to 15 grains).

EXTRACTUM TARAXACI LIQUIDUM

(Ext. Tarax. Liq.)

Liquid Extract of Taraxacum

	<i>Metric</i>	<i>Imperial</i>
Taraxacum, dried, in moderately coarse powder	1000 g.	20 oz.
Alcohol (60 per cent.)	2000 ml.	40 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the taraxacum with the alcohol, set aside in a closed vessel for forty-eight hours, then press out and reserve 500 millilitres (10 fluid ounces) of liquid. Mix the pressed residue with 2000 millilitres (40 fluid ounces) of distilled water, set aside for forty-eight hours, press out the liquid, strain, evaporate to about 500 millilitres (10 fluid ounces), mix it with the reserved portion, add, if necessary, sufficient distilled water to produce the required volume, and filter.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

EXTRACTUM THYMI LIQUIDUM

(Ext. Thym. Liq.)

Liquid Extract of Thyme

Synonym—*Extractum Thymi Vulgaris Liquidum.*

	<i>Metric</i>	<i>Imperial</i>
Thyme, in moderately coarse powder	1000 g.	20 oz.
Glycerin	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	a sufficient quantity	
Distilled Water	a sufficient quantity	

Exhaust the thyme by percolation, using as menstruum first a mixture of the glycerin with 250 millilitres (5 fluid ounces) of alcohol (90 per cent.) and 650 millilitres (13 fluid ounces) of distilled water, and then a mixture of one volume of alcohol (90 per cent.) with three volumes of distilled water. Reserve the first 850 millilitres (17 fluid ounces) of percolate, evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add, if necessary, sufficient of the second menstruum to produce 1000 millilitres (20 fluid ounces).

Dose.— 0.6 to 4 millilitres (10 to 60 minims).

EXTRACTUM THYROIDEI LIQUIDUM

(Ext. Thyroid. Liq.)

Liquid Extract of Thyroid

	<i>Metric</i>	<i>Imperial</i>
Thyroid	220 g.	4 oz. 175 gr.
Dilute Hydrochloric Acid ..	25 ml.	$\frac{1}{2}$ fl. oz.
Double Chloroform Water ..	200 ml.	4 fl. oz.
Glycerin to 1000 ml.	to 20 fl. oz.

Triturate the thyroid with 400 millilitres (8 fluid ounces) of glycerin, add the dilute hydrochloric acid and double chloroform water and set aside for twenty-four hours; strain through linen, pressing strongly, and add sufficient glycerin to produce the required volume.

Dose.— 0.06 to 1.2 millilitres (1 to 20 minims).

EXTRACTUM TUSSILAGINIS LIQUIDUM

(Ext. Tussilag. Liq.)

Liquid Extract of Coltsfoot

	<i>Metric</i>	<i>Imperial</i>
Coltsfoot Flower, in moderately coarse powder	1000 g.	20 oz.
Alcohol (90 per cent.) .. .	250 ml.	5 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Exhaust the coltsfoot flower with the distilled water by percolation. Evaporate the percolate to 750 millilitres (15 fluid ounces), add the alcohol and allow to stand for fourteen days; filter and pass, if necessary, sufficient distilled water through the filter to produce the required volume.

Dose.— 0.6 to 2 millilitres (10 to 30 minims).

EXTRACTUM VALERIANÆ

(Ext. Valerian.)

Extract of Valerian

	<i>Metric</i>	<i>Imperial</i>
Valerian, in moderately fine powder	1000 g.	16 oz.
Alcohol (70 per cent.)	a sufficient quantity	

Exhaust the drug with the alcohol by percolation and evaporate the percolate to a firm extract.

It should be **stored** in well-closed containers.

Dose.— 0·06 to 0·3 gramme (1 to 5 grains).

In making this preparation the alcohol (70 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM VALERIANÆ LIQIDUM

(Ext. Valerian. Liq.)

Liquid Extract of Valerian

	<i>Metric</i>	<i>Imperial</i>
Valerian, freshly dried, in moderately coarse powder ..	1000 g.	20 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the valerian with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate; evaporate the subsequent percolate to a thin syrup, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days and filter.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

EXTRACTUM VIBURNI

(Ext. Viburn.)

Extract of Black Haw

	<i>Metric</i>	<i>Imperial</i>
Black Haw, in moderately fine powder	1000 g.	16 oz.
Alcohol (70 per cent.)	a sufficient quantity	

Exhaust the black haw with the alcohol by percolation and evaporate the percolate to a soft extract.

Dose.— 0·2 to 0·5 gramme (3 to 8 grains).

In making this preparation the alcohol (70 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

EXTRACTUM VIBURNI LIQUIDUM

(Ext. Viburn. Liq.)

Liquid Extract of Black Haw

	<i>Metric</i>	<i>Imperial</i>
Black Haw, in moderately fine powder	1000 g.	20 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Exhaust the black haw with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Evaporate the subsequent percolate to a soft extract, dissolve it in the reserved portion and add sufficient of the alcohol to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

GARGARISMATA**Gargles**

A gargle is an aqueous solution for use as a prophylactic or in the treatment of an affection of the throat. The particular method of using a gargle is intended to bring it into intimate contact with the membranous lining of the throat. It is not intended to act as a protective covering to the membrane, and therefore oily substances requiring suspending agents, and drugs of a mucilaginous nature, should not be used.

In the case of the following gargles, when no strength is indicated by the prescriber, aqueous solutions of the following strengths should be supplied.

Gargarisma Boracis.—Borax, 3·4 per cent. w/v.

Gargarisma Chromii Trioxidi.—Chromium trioxide, 0·2 per cent. w/v.

Gargarisma Formaldehydi.—Solution of formaldehyde, 0·2 per cent. v/v.

Gargarisma Kino Eucalypti.—Liquid extract of eucalyptus kino, 6·25 per cent. v/v.

Gargarisma Potassii Permanganatis.—Potassium permanganate, 0·025 per cent. w/v.

Gargarisma Sodii Bicarbonatis.—Sodium bicarbonate, 5 per cent. w/v.

GARGARISMA ACIDI TANNICI

(Garg. Acid. Tann.)

Tannic Acid Gargle

	<i>Metric</i>	<i>Imperial</i>
Glycerin of Tannic Acid	125 ml.	2½ fl. oz.
Distilled Water	to 1000 ml.	20 fl. oz.

Mix.

GARGARISMA ALUMINIS

(Garg. Alum.)

Alum Gargle

		<i>Metric</i>	<i>Imperial</i>
Glycerin of Alum	125 ml.	2½ fl. oz.
Acid Infusion of Roses	to 1000 ml.	to 20 fl. oz.
Mix.			

GARGARISMA CHLORI

(Garg. Chlor.)

Chlorine Gargle

		<i>Metric</i>	<i>Imperial</i>
Potassium Chlorate	22.9 g.	200 gr.
Hydrochloric Acid	4.2 ml.	40 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Place the powdered potassium chlorate in a dry bottle, pour the acid upon it and set aside, loosely corked, for ten minutes; then add the distilled water in four or five successive portions, shaking between each addition, so that the gas may be dissolved as completely as possible. It should be recently prepared and not exposed to sunlight, and should be diluted before use with one or more parts of water.

GARGARISMA PHENOLIS

(Garg. Phenol.)

Phenol Gargle*Synonym*—Gargarisma Acidi Carbolici.

		<i>Metric</i>	<i>Imperial</i>
Glycerin of Phenol	50 ml.	1 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.
Mix.			

GARGARISMA POTASSII CHLORATIS

(Garg. Pot. Chlorat.)

Potassium Chlorate Gargle

		<i>Metric</i>	<i>Imperial</i>
Potassium Chlorate	22.9 g.	200 gr.
Dilute Hydrochloric Acid	10.4 ml.	100 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium chlorate in about 900 millilitres (18 fluid ounces) of the distilled water, add the dilute hydrochloric acid and sufficient distilled water to produce the required volume.

GELATINUM CODEINÆ

(Gelat. Codein.)

Codeine Jelly

	<i>Metric</i>	<i>Imperial</i>
Codeine	2.0 g.	22 gr.
Citric Acid	20.0 g.	$\frac{1}{2}$ oz.
Gelatin	80.0 g.	2 oz.
Glycerin	480.0 ml.	12 fl. oz.
Oil of Lemon	0.4 ml.	5 m.
Solution of Tolu	360.0 ml.	9 fl. oz.

Soak the gelatin in 300 millilitres ($7\frac{1}{2}$ fluid ounces) of the solution of tolu, add the glycerin, and heat until dissolved. Dissolve the codeine and citric acid in the remaining 60 millilitres ($1\frac{1}{2}$ fluid ounces) of the solution of tolu, add the solution to the solution of gelatin, add the oil of lemon, and mix.

Dose.—4 grammes (1 drachm).

GELATINUM ZINCI ET ICHTHAMMOLIS

(Gelat. Zinc. et Ichtham.)

Gelatin of Zinc and Ichthammol

Synonyms—Pasta Zinci et Ichthammolis; Unna's Paste with Ichthammol.

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide, finely sifted	150 g.	3 oz.
Ichthammol	20 g.	175 gr.
Gelatin	150 g.	3 oz.
Glycerin	350 ml.	7 fl. oz.
Distilled Water	350 ml.	7 fl. oz.

Soften the gelatin by soaking it in the water, then add the glycerin previously mixed with the zinc oxide and the ichthammol to form a smooth paste; heat on a water-bath until the gelatin is dissolved, stir until uniform, and pour into a flat dish or tray to solidify.

GLYCERINUM ACIDI GALLICI

(Glycer. Acid. Gall.)

Glycerin of Gallic Acid

	<i>Metric</i>	<i>Imperial</i>
Gallic Acid	150 g.	2 oz. 175 gr.
Glycerin	to 1000 g.	to 16 oz.

Triturate the gallic acid with sufficient glycerin to produce the

required weight and warm the mixture on a water-bath, with frequent stirring, until solution is complete.

Dose.— 0·6 to 4 millilitres (10 to 60 minims)

GLYCERINUM ATROPINÆ

(*Glycer. Atrop.*)

Glycerin of Atropine

	<i>Metric</i>	<i>Imperial</i>
Solution of Atropine Sulphate ..	250·0 ml.	5 fl. oz.
Compound Tincture of Lavender ..	10·4 ml.	100 m.
Glycerinto 1000·0 ml.		to 20 fl. oz.
Mix.		

GLYCERINUM BELLADONNÆ

(*Glycer. Bellad.*)

Glycerin of Belladonna

	<i>Metric</i>	<i>Imperial</i>
Green Extract of Belladonna ..	500·0 g.	8 oz.
Distilled Water, boiling	62·5 ml.	1 fl. oz.
Glycerinto 1000·0 g.		to 16 oz.

Triturate the green extract of belladonna with the boiling distilled water to produce a smooth paste, add sufficient glycerin to produce the required weight, and mix.

GLYCERINUM BISMUTHI CARBONATIS

(*Glycer. Bism. Carb.*)

Glycerin of Bismuth Carbonate

	<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	500 g.	10 oz.
Glycerinto 500 ml.		10 fl. oz.
Distilled Waterto 1000 ml.		to 20 fl. oz.

Mix.

Dose.— 0·6 to 4 millilitres (10 to 60 minims).

GLYCERINUM CARMINI

(Glycer. Carmin.)

Glycerin of Carmine

	<i>Metric</i>	<i>Imperial</i>
Carmine	62.5 g.	1½ oz.
Potassium Carbonate	10.0 g.	87½ gr.
Potassium Citrate	100.0 g.	2 oz.
Glycerin	200.0 ml.	4 fl. oz.
Distilled Waterto 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium carbonate in 600 millilitres (12 fluid ounces) of distilled water, and digest the carmine in the solution on a water-bath until the colouring matter is dissolved; then strain, cool, add the glycerin and potassium citrate, and sufficient distilled water to produce the required volume.

GLYCERINUM CROCI

(Glycer. Croc.)

Glycerin of Saffron

	<i>Metric</i>	<i>Imperial</i>
Saffron	25 g.	½ oz.
Alcohol (60 per cent.)	500 ml.	10 fl. oz.
Glycerin	500 ml.	10 fl. oz.

Mix the glycerin with the alcohol, digest the saffron in the mixture for one hour at a gentle heat, and filter. It should be **stored** in completely-filled, well-closed bottles, and protected from light.

GLYCERINUM DIAMORPHINÆ

(Glycer. Diamorph.)

Glycerin of Diamorphine

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0.5 g.	4½ gr.
Distilled Water	100.0 ml.	2 fl. oz.
Concentrated Acid Infusion of Roses	62.5 ml.	1½ fl. oz.
Syrup	450.0 ml.	9 fl. oz.
Chloroform	2.0 ml.	19 m.
Alcohol (90 per cent.)	4.0 ml.	38 m.
Glycerinto 1000.0 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride in the distilled water and gradually add the syrup and concentrated acid infusion of roses, shaking after each addition; then add the chloroform previously dissolved in the alcohol, and sufficient glycerin to produce the required volume.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

GLYCERINUM FERRI PERCHLORIDI

(Glycer. Ferr. Perchlor.)

Glycerin of Ferric Chloride

	<i>Metric</i>	<i>Imperial</i>
Solution of Ferric Chloride ..	500 ml.	10 fl. oz.
Glycerin	500 ml.	10 fl. oz.
Mix.		

GLYCERINUM GLYCEROPHOSPHATUM COMPOSITUM

(Glycer. Glycerophosph. Co.)

Compound Glycerin of Glycerophosphates

Synonyms—Elixir Glycerophosphatum; Elixir of Glycerophosphates; Glycerol Glycerophosphatis.

	<i>Metric</i>	<i>Imperial</i>
Calcium Glycerophosphate ..	22.9 g.	200 gr.
Magnesium Glycerophosphate ..	11.4 g.	100 gr.
Iron Glycerophosphate	5.7 g.	50 gr.
Solution of Potassium Glycerophosphate	22.9 g.	200 gr.
Solution of Sodium Glycerophosphate	22.9 g.	200 gr.
Potassium Citrate	11.4 g.	100 gr.
Glycerophosphoric Acid ..	20.8 ml.	200 m.
Triple Orange-flower Water ..	12.5 ml.	120 m.
Cherry-laurel Water	20.8 ml.	200 m.
Solution of Bordeaux B ..	31.2 ml.	300 m.
Glycerin	500.0 ml.	10 fl. oz.
Double Chloroform Water .. to 1000.0 ml.		to 20 fl. oz.

Dissolve the potassium citrate in 350 millilitres (7 fluid ounces) of double chloroform water, add the solution of potassium glycerophosphate and solution of sodium glycerophosphate and dissolve the calcium, magnesium and iron glycerophosphates in the mixture. Add the glycerophosphoric acid, triple orange-flower water, cherry-laurel water, solution of bordeaux B, glycerin, and sufficient double chloroform water to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

GLYCERINUM GLYCEROPHOSPHATUM CUM MEDULLA RUBRA

(Glyc. Glycerophosph. c. Medull. Rub.)

Glycerin of Glycerophosphates with Red Bone Marrow

Synonyms—Elixir Glycerophosphatum cum Medulla Rubra; Elixir of Glycerophosphates with Red Bone Marrow; Glycerol Glycerophosphatis cum Medulla Rubra.

	<i>Metric</i>	<i>Imperial</i>
Extract of Red Bone Marrow ..	500 ml.	10 fl. oz.
Compound Glycerin of Glycerophosphates to 1000 ml.		to 20 fl. oz.

Mix.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

GLYCERINUM HYPOPHOSPHITUM COMPOSITUM

(*Glycer. Hypophosph. Co.*)

Compound Glycerin of Hypophosphites

Synonym—Glycerol Hypophosphitis.

	<i>Metric</i>	<i>Imperial</i>
Calcium Hypophosphite ..	17·2 g.	150 gr.
Manganese Hypophosphite ..	8·6 g.	75 gr.
Potassium Hypophosphite ..	17·2 g.	150 gr.
Quinine	8·3 g.	73 gr.
Strychnine	0·23 g.	2 gr.
Solution of Iron Hypophosphite	200·0 ml.	4 fl. oz.
Hypophosphorous Acid	12·5 ml.	120 m.
Distilled Water	150·0 ml.	3 fl. oz.
Glycerin to 1000·0 ml.		to 20 fl. oz.

Dissolve the hypophosphites in the distilled water, and the quinine and strychnine in a mixture of the solution of iron hypophosphite and the hypophosphorous acid, mix the solutions and add sufficient glycerin to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

GLYCERINUM ICHTHAMMOLIS

(*Glycer. Ichtham.*)

Glycerin of Ichthammol

Synonym—Glycerin of Ammonium Ichthosulphonate.

	<i>Metric</i>	<i>Imperial</i>
Ichthammol	100 g.	1 oz.
Glycerin	900 g.	9 oz.

Mix.

GLYCERINUM IODOFORMI

(Glycer. Iodof.)

Glycerin of Iodoform*Synonym*—Emulsio Iodoformi.

	<i>Metric</i>	<i>Imperial</i>
Iodoform	100 g.	2 oz.
Alcohol (90 per cent.)	a sufficient quantity	
Glycerin	700 g.	14 oz.
Sterilised Water	200 ml.	4 fl. oz.

Triturate the iodoform with sufficient alcohol to make a smooth paste, using a sterilised mortar and pestle. Mix the glycerin and the sterilised water in a wide-mouthed flask, sterilise with the aid of heat, add the mixture to the iodoform, stir well and transfer to a sterile container.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

GLYCERINUM PANCREATINI

(Glycer. Pancreatin.)

Glycerin of Pancreatin

	<i>Metric</i>	<i>Imperial</i>
Pancreatin	100 g.	2 oz.
Glycerin	500 ml.	10 fl. oz.
Simple Elixir	50 ml.	1 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Macerate the pancreatin in 300 millilitres (6 fluid ounces) of the distilled water for twenty-four hours, add the glycerin, and macerate for seven days; add the simple elixir and sufficient distilled water to produce the required volume, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

GLYCERINUM PAPAINI

(Glycer. Papain.)

Glycerin of Papain

	<i>Metric</i>	<i>Imperial</i>
Papain	90 g.	1 oz. 350 gr.
Dilute Hydrochloric Acid	80 ml.	1 fl. oz. 288 m.
Simple Elixir	50 ml.	1 fl. oz.
Glycerin	to 1000 ml.	to 20 fl. oz.

Digest the papain for seven days in a mixture of the dilute hydrochloric acid and 700 millilitres (14 fluid ounces) of glycerin, filter through flannel, add the simple elixir and sufficient glycerin to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

GLYCERINUM PEPSINI

(*Glycer. Pepsin.*)

Glycerin of Pepsin

	<i>Metric</i>	<i>Imperial</i>
Pepsin	100.0 g.	2 oz.
Hydrochloric Acid	11.5 ml.	110 m.
Glycerin	600.0 ml.	12 fl. oz.
Distilled Water to 1000.0 ml.	to 20 fl. oz.

Mix the hydrochloric acid, glycerin and 250 millilitres (5 fluid ounces) of distilled water, and dissolve the pepsin in the mixture; add sufficient distilled water to produce the required volume, set aside for twenty minutes and filter.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

GLYCERINUM PEPSINI FORTIUS

(*Glycer. Pepsin. Fort.*)

Stronger Glycerin of Pepsin

Synonym—Glycerol of Pepsin.

	<i>Metric</i>	<i>Imperial</i>
Pepsin	150 g.	3 oz.
Dilute Hydrochloric Acid	50 ml.	1 fl. oz.
Glycerin	500 ml.	10 fl. oz.
Simple Elixir	50 ml.	1 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Add the pepsin to 300 millilitres (6 fluid ounces) of the distilled water previously mixed with the dilute hydrochloric acid and glycerin; shake well and set aside until clear; decant or filter, add the simple elixir and, if necessary, sufficient distilled water to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

GLYCERINUM PLUMBI SUBACETATIS**(Glycer. Plumb. Subacet.)****Glycerin of Lead Subacetate**

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Lead Subacetate	500 ml.	10 fl. oz.
Glycerin	500 ml.	10 fl. oz.
Distilled Water	a sufficient quantity	

Evaporate the strong solution of lead subacetate to dryness on a water-bath, add the glycerin and warm gently until the residue is dissolved; cool, add distilled water until the specific gravity of the mixture is 1.48 and filter if necessary.

GLYCERINUM THYMOLIS COMPOSITUM**(Glycer. Thymol. Co.)****Compound Glycerin of Thymol***Synonym*—Glycerinum Thymol Alkalinum.

	<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	10.0 g.	87½ gr.
Borax	20.0 g.	175 gr.
Sodium Benzoate	8.0 g.	70 gr.
Sodium Salicylate	5.2 g.	45 gr.
Menthol	0.3 g.	2½ gr.
Thymol	0.5 g.	4½ gr.
Eucalyptol	1.3 ml.	13 m.
Oil of Pumilio Pine	0.5 ml.	5 m.
Oil of Sweet Birch	0.3 ml.	3 m.
Alcohol (90 per cent.)	25.0 ml.	½ fl. oz.
Glycerin	100.0 ml.	2 fl. oz.
Solution of Bordeaux B	10.4 ml.	100 m.
Distilled Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the salts in 800 millilitres (16 fluid ounces) of the distilled water and add the glycerin; dissolve the menthol, thymol, eucalyptol and oils in the alcohol, triturate with 25 grammes (½ ounce) of purified talc or kaolin, add the mixture gradually to the solution of salts, filter, add the solution of bordeaux B and sufficient distilled water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

GLYCERINUM TRAGACANTHÆ

(Glycer. Trag.)

Glycerin of Tragacanth

	<i>Metric</i>	<i>Imperial</i>
Tragacanth, in powder	200 g.	3 oz.
Glycerin	600 ml.	9 fl. oz.
Distilled Water	200 ml.	3 fl. oz.

Mix the glycerin with the tragacanth, add the distilled water, and triturate until a homogeneous paste is produced.

GLYCOGELATINUM

(Glycogelat.)

Glycogelatin

	<i>Metric</i>	<i>Imperial</i>
Gelatin	200.0 g.	3 oz. 87½ gr.
Glycerin	400.0 g.	6 oz. 175 gr.
Sucrose	50.0 g.	350 gr.
Citric Acid	20.0 g.	140 gr.
Sodium Benzoate	2.0 g.	14 gr.
Oil of Lemon	1.0 ml.	8 m.
Solution of Bordeaux B	10.4 ml.	80 m.
Triple Orange-flower Water	62.5 ml.	1 fl. oz.
Distilled Water	to 1000.0 g.	to 16 oz.

Soak the gelatin in one and a half times its weight of distilled water until softened, add the glycerin, and heat on a water-bath until the gelatin is dissolved and the mass weighs 850 grammes (13½ ounces); add the sucrose, citric acid and sodium benzoate previously dissolved in the triple orange-flower water, then add the oil of lemon, the solution of bordeaux B and sufficient distilled water to produce the required weight. Strain through muslin and allow to cool.

GRANULÆ EFFERVESCENTES**Effervescent Granules**

Effervescent granules consist of an effervescing basis of citric and tartaric acids and sodium bicarbonate, with or without sugar, and other ingredients. The ingredients are thoroughly mixed, placed in a suitable vessel and heated to between 95° and 105°. When the mixture has, by careful manipulation, assumed a uniformly plastic condition, it is passed

through a sieve of suitable mesh to produce granules of the required size. The granules are dried at a temperature not exceeding 55° and should be **stored** in well-closed containers.

AMMONII BROMIDUM EFFERVESCENS

(Ammon. Brom. Efferv.)

Effervescent Ammonium Bromide

			<i>Metric</i>	<i>Imperial</i>
Ammonium Bromide	80 g.	1 oz. 122½ gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	160 g.	2 oz. 245 gr.
Sucrose	160 g.	2 oz. 245 gr.

Prepare as described under Granulæ Effervescentes.

Dose.— 5 to 30 grammes (75 grains to 1 ounce).

CAFFEINÆ CITRAS EFFERVESCENS

(Caffein. Cit. Efferv.)

Effervescent Caffeine Citrate

			<i>Metric</i>	<i>Imperial</i>
Caffeine Citrate	40 g.	280 gr.
Sodium Bicarbonate	570 g.	9 oz. 52½ gr.
Tartaric Acid	300 g.	4 oz. 350 gr.
Citric Acid	195 g.	3 oz. 52½ gr.

Prepare as described under Granulæ Effervescentes.

Dose.— 4 to 8 grammes (1 to 2 drachms).

LITHII CITRAS EFFERVESCENS

(Lith. Cit. Efferv.)

Effervescent Lithium Citrate

			<i>Metric</i>	<i>Imperial</i>
Lithium Citrate	50 g.	350 gr.
Sodium Bicarbonate	580 g.	9 oz. 122½ gr.
Tartaric Acid	310 g.	4 oz. 420 gr.
Citric Acid	210 g.	3 oz. 157½ gr.

Prepare as described under Granulæ Effervescentes.

Dose.— 4 to 8 grammes (1 to 2 drachms).

MAGNESII SULPHAS EFFERVESCENS

(Mag. Sulph. Efferv.)

Effervescent Magnesium Sulphate*Synonym*—Effervescent Epsom Salts.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Magnesium Sulphate	385 g.	6 oz. 70 gr.
Sodium Bicarbonate	360 g.	5 oz. 332½ gr.
Tartaric Acid	190 g.	3 oz. 17½ gr.
Citric Acid	125 g.	2 oz.
Sucrose	105 g.	1 oz. 297½ gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—For repeated administration, 4 to 12 grammes (1 to 3 drachms); for a single administration, 15 to 30 grammes (½ to 1 ounce).**PHENACETINUM EFFERVESCENS**

(Phenacet. Efferv.)

Effervescent Phenacetin

	<i>Metric</i>	<i>Imperial</i>
Phenacetin	50 g.	350 gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	175 g.	2 oz. 350 gr.
Sucrose	175 g.	2 oz. 350 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—4 to 8 grammes (1 to 2 drachms).**PHENACETINUM CUM CAFFEINA EFFERVESCENS**

(Phenacet. c. Caffein. Efferv.)

Effervescent Phenacetin with Caffeine

	<i>Metric</i>	<i>Imperial</i>
Phenacetin	50 g.	350 gr.
Caffeine Citrate	15 g.	105 gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	175 g.	2 oz. 350 gr.
Sucrose	160 g.	2 oz. 245 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—4 to 8 grammes (1 to 2 drachms).

PHENAZONUM EFFERVESCENS

(Phenazon. Efferv.)

Effervescent Phenazone*Synonym*—Effervescent Antipyrin.

			<i>Metric</i>	<i>Imperial</i>
Phenazone	80 g.	1 oz. 122½ gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	160 g.	2 oz. 245 gr.
Sucrose	160 g.	2 oz. 245 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—4 to 8 grammes (1 to 2 drachms).**PHENAZONUM CUM CAFFEINA EFFERVESCENS**

(Phenazon. c. Caffein. Efferv.)

Effervescent Phenazone with Caffeine*Synonym*—Effervescent Antipyrin with Caffeine.

			<i>Metric</i>	<i>Imperial</i>
Phenazone	80 g.	1 oz. 122½ gr.
Caffeine Citrate	15 g.	105 gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	160 g.	2 oz. 245 gr.
Sucrose	145 g.	2 oz. 140 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—4 to 8 grammes (1 to 2 drachms).**PIPERAZINA EFFERVESCENS**

(Piperaz. Efferv.)

Effervescent Piperazine

			<i>Metric</i>	<i>Imperial</i>
Piperazine	80 g.	1 oz. 122½ gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	160 g.	2 oz. 245 gr.
Sucrose	160 g.	2 oz. 245 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**—4 to 12 grammes (1 to 3 drachms).

POTASSII CITRAS EFFERVESCENS

(Pot. Cit. Efferv.)

Effervescent Potassium Citrate

			<i>Metric</i>	<i>Imperial</i>
Potassium Citrate	160 g.	2 oz. 245 gr.
Sodium Bicarbonate	460 g.	7 oz. 157½ gr.
Tartaric Acid	240 g.	3 oz. 367½ gr.
Citric Acid	140 g.	2 oz. 105 gr.
Sucrose	140 g.	2 oz. 105 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**— 4 to 8 grammes (1 to 2 drachms).**SODII CITRO-TARTRAS EFFERVESCENS**

(Sod. Citro-Tart. Efferv.)

Effervescent Sodium Citro-Tartrate

			<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	510 g.	8 oz. 20 gr.
Tartaric Acid	270 g.	4 oz. 140 gr.
Citric Acid	180 g.	2 oz. 385 gr.
Sucrose	150 g.	2 oz. 175 gr.

Prepare as described under *Granulæ Effervescentes*.**Dose.**— 4 to 8 grammes (1 to 2 drachms).**GUTTÆ****Drops for the Eye**

Drops for the eye are solutions of alkaloids or other substances in water or oil. They are used for anæsthetic, antiseptic, diagnostic, mydriatic and miotic purposes. The apparatus used in the preparation of drops for the eye, the containers for the solutions, and also the solutions themselves, should be sterilised. Drops for the eye, isotonic with the lachrymal secretion, may be prepared as described under *Collyria*.

GUTTÆ COCAINÆ

(Gutt. Cocain.)

Cocaine Eye Drops*Synonym* Factory Eye Drops.

			<i>Metric</i>	<i>Imperial</i>
Cocaine	0.5 g.	5 gr.
Mercuric Chloride	0.033 g.	½ gr.
Dehydrated Alcohol	1.0 ml.	11 m.
Castor Oil	95.0 g.	950 gr.

Dissolve the cocaine in the castor oil, in a dry vessel, with the aid of gentle heat; allow to cool, add the mercuric chloride dissolved in the dehydrated alcohol, and mix. It should be **stored** protected from sunlight, and should not be used after long storage.

GUTTÆ FLUORESCINÆ

(Gutt. Fluoresc.)

Fluorescein Eye Drops

Synonym—Liquor Fluoresceinæ.

		<i>Metric</i>	<i>Imperial</i>
Soluble Fluorescein	2 g.	35 gr.
Sterilised Water	to 100 ml.	to 4 fl. oz.

Dissolve.

GUTTÆ PHYSOSTIGMINÆ

(Gutt. Physostig.)

Physostigmine Eye Drops

Synonyms—Guttæ Eserinæ; Eserine Eye Drops.

		<i>Metric</i>	<i>Imperial</i>
Physostigmine Salicylate	1 g.	17½ gr.
Boric Acid	3 g.	52½ gr.
Sterilised Water	to 100 ml.	to 4 fl. oz.

Dissolve.

The solution should be freshly prepared, or, if **stored**, it should be kept in completely-filled, well-closed containers protected from light.

GUTTÆ PHYSOSTIGMINÆ OLEOSÆ

(Gutt. Physostig. Oleos.)

Eye Drops of Physostigmine in Oil

Synonym—Guttæ Eserinæ Oleosæ.

		<i>Metric</i>	<i>Imperial</i>
Physostigmine	0.5 g.	8¾ gr.
Castor Oil	to 100.0 ml.	to 4 fl. oz.

Dissolve with the aid of gentle heat.

GUTTÆ PILOCARPINÆ**(Gutt. Pilocarp.)****Pilocarpine Eye Drops**

		<i>Metric</i>	<i>Imperial</i>
Pilocarpine Nitrate	0.5 g.	8 $\frac{3}{4}$ gr.
Sterilised Water	to 100.0 ml.	to 4 fl. oz.
Dissolve.			

INFUSA**Infusions**

Infusions are dilute solutions containing the water-soluble extractive of vegetable drugs. They are prepared by macerating drugs in distilled water for short periods of time, varying from fifteen minutes to two hours. The volume of the product is indefinite, depending upon the quantity of menstruum retained by the marc, which should not be pressed. The degree of comminution of the drug, the temperature at which infusion is commenced, and the period of maceration depend upon the nature of the drug and the constituents to be extracted.

Infusions should be prepared in earthenware vessels. If hot water is used in preparing the infusion, it should be weighed into the vessel, previously tared and warmed, and containing the drug, preferably suspended by some suitable contrivance, or enclosed in muslin so as to be immediately below the surface of the water; if the drug sinks to the bottom of the vessel, the mixture should be stirred occasionally. When the specified period of infusion has expired, the product is strained. It is important to remove the marc from infusions as soon as the period of maceration has elapsed, and it is usually necessary to allow the preparations to cool before use. Infusions of drugs containing an active principle which is easily soluble, and those containing an appreciable quantity of starch, are prepared with cold water.

Fresh infusions should be dispensed within twelve hours of their preparation. When an infusion is ordered, the fresh infusion not being specified, either the fresh infusion, or the concentrated infusion suitably diluted, may be dispensed. Concentrated infusions when diluted with seven times their volume of distilled water yield preparations which are approximately equivalent in strength, but not in flavour, to the corresponding fresh infusions, and differ also in containing a small proportion of alcohol. Concentrated infusions of drugs such as digitalis and ergot are unstable, and only the fresh infusions should be used.

Infusions for which special formulæ are not given, and for which there is no stated strength, may be prepared by infusing for fifteen minutes 50 grammes (1 ounce) of the drug, in coarse powder, in 1000 millilitres (20 fluid ounces) of boiling distilled water, and straining.

INFUSUM AURANTII COMPOSITUM CONCENTRATUM

(Inf. Aurant. Co. Conc.)

Concentrated Compound Infusion of Orange Peel

	<i>Metric</i>	<i>Imperial</i>
Dried Bitter-Orange Peel, cut small	200 g.	4 oz.
Dried Lemon Peel, cut small	80 g.	1 oz. 262 gr.
Clove, bruised	25 g.	$\frac{1}{2}$ oz.
Alcohol (25 per cent.)	1350 ml.	27 fl. oz.

Macerate in a covered vessel for forty-eight hours the dried bitter-orange peel, the dried lemon peel and the clove in 1000 millilitres (20 fluid ounces) of the alcohol and press out the liquid. To the pressed marc add the remainder of the alcohol and macerate for twenty-four hours; press, add the liquid to the product of the first pressing, allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 21 to 24 per cent. v/v of ethyl alcohol.

INFUSUM AURANTII COMPOSITUM RECENS

(Inf. Aurant. Co. Rec.)

Fresh Compound Infusion of Orange Peel

	<i>Metric</i>	<i>Imperial</i>
Dried Bitter-Orange Peel, cut small	25 g.	$\frac{1}{2}$ oz.
Lemon Peel, cut small	10 g.	87 $\frac{1}{2}$ gr.
Clove, bruised	5 g.	43 $\frac{3}{4}$ gr.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh compound infusion of orange peel should be used within twelve hours of its preparation.

When compound infusion of orange peel (Infusum Aurantii Compositum) is prescribed, fresh infusion not being specified, either Infusum Aurantii Compositum Recens, or Infusum Aurantii Compositum Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM CASCARILLÆ CONCENTRATUM

(Inf. Cascaril. Conc.)

Concentrated Infusion of Cascarilla

	<i>Metric</i>	<i>Imperial</i>
Cascarilla, in coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	1250 ml.	25 fl. oz.

Macerate the cascarilla in 1000 millilitres (20 fluid ounces) of the alcohol in a covered vessel for forty-eight hours and press out the liquid. To the pressed marc add the remainder of the alcohol and macerate for twenty-four hours; press, add the liquid to the product of the first pressing, allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

INFUSUM CASCARILLÆ RECENS

(Inf. Cascaril. Rec.)

Fresh Infusion of Cascarilla

	<i>Metric</i>	<i>Imperial</i>
Cascarilla, in coarse powder ..	50 g.	1 oz.
Distilled Water, boiling ..	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of cascarilla should be used within twelve hours of its preparation.

When infusion of cascarilla (Infusum Cascarillæ) is prescribed, fresh infusion not being specified, either Infusum Cascarillæ Recens, or Infusum Cascarillæ Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM CHIRATÆ CONCENTRATUM

(Inf. Chirat. Conc.)

Concentrated Infusion of Chiretta

	<i>Metric</i>	<i>Imperial</i>
Chiretta, cut small ..	400 g.	8 oz.
Alcohol (25 per cent.) ..	to 1000 ml.	to 20 fl. oz.

Extract the chiretta with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected, evaporate to a syrupy consistence, dissolve the residue in the reserved portion and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 19 to 23 per cent. v/v of ethyl alcohol.

INFUSUM CHIRATÆ RECENS

(Inf. Chirat. Rec.)

Fresh Infusion of Chiretta

	<i>Metric</i>	<i>Imperial</i>
Chiretta, cut small	50 g.	1 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of chiretta should be used within twelve hours of its preparation.

When infusion of chiretta (Infusum Chiratæ) is prescribed, fresh infusion not being specified, either Infusum Chiratæ Recens, or Infusum Chiratæ Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM CINCHONÆ ACIDUM CONCENTRATUM

(Inf. Cinchon. Acid. Conc.)

Concentrated Acid Infusion of Cinchona

	<i>Metric</i>	<i>Imperial</i>
Cinchona, in moderately fine powder	400 g.	8 oz.
Aromatic Sulphuric Acid	100 ml.	2 fl. oz.
Alcohol (20 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the cinchona with the alcohol by percolation, reserving the first 850 millilitres (17 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected; evaporate to a syrupy consistence, dissolve the residue in the aromatic sulphuric acid, add to the reserved portion and add, if necessary, sufficient alcohol (20 per cent.), to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 24 to 27 per cent. v/v of ethyl alcohol.

INFUSUM CINCHONÆ ACIDUM RECENS

(Inf. Cinchon. Acid. Rec.)

Fresh Acid Infusion of Cinchona

	<i>Metric</i>	<i>Imperial</i>
Cinchona, in moderately fine powder	50.0 g.	1 oz.
Aromatic Sulphuric Acid	12.5 ml.	120 m.
Distilled Water, boiling	1000.0 ml.	20 fl. oz.

Mix the cinchona with the distilled water in a covered vessel, add the aromatic sulphuric acid, infuse for one hour, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh acid infusion of cinchona should be used within twelve hours of its preparation.

When acid infusion of cinchona (*Infusum Cinchonæ Acidum*) is prescribed, fresh infusion not being specified, either *Infusum Cinchonæ Acidum Recens*, or *Infusum Cinchonæ Acidum Concentratum* diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM CUSPARIÆ CONCENTRATUM

(*Inf. Cuspar. Conc.*)

Concentrated Infusion of Cusparia

	<i>Metric</i>	<i>Imperial</i>
Cusparia, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	1300 ml.	26 fl. oz.

Macerate the cusparia with 1000 millilitres (20 fluid ounces) of the alcohol in a covered vessel for forty-eight hours and press out the liquid; to the pressed marc add the remainder of the alcohol, macerate for twenty-four hours, press, add the liquid to the product of the first pressing, allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

When infusion of cusparia (*Infusum Cuspariæ*) is prescribed, this concentrated infusion diluted with seven times its volume of distilled water may be dispensed.

INFUSUM ERGOTÆ RECENS

(*Inf. Ergot. Rec.*)

Fresh Infusion of Ergot

	<i>Metric</i>	<i>Imperial</i>
Ergot, freshly crushed	50 g.	1 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 30 to 60 millilitres (1 to 2 fluid ounces).

For dispensing purposes, fresh infusion of ergot should be used within twelve hours of its preparation.

When infusion of ergot (*Infusum Ergotæ*) is prescribed, *Infusum Ergotæ Recens* should be dispensed.

INFUSUM KRAMERIÆ CONCENTRATUM

(Inf. Kramer. Conc.)

Concentrated Infusion of Krameria*Synonym*—Concentrated Infusion of Rhatany.

	<i>Metric</i>	<i>Imperial</i>
Krameria, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the krameria with the alcohol by percolation reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected; evaporate to a syrupy consistence, dissolve the residue in the reserved portion and add if necessary sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

INFUSUM KRAMERIÆ RECENS

(Inf. Kramer. Rec.)

Fresh Infusion of Krameria*Synonym*—Infusion of Rhatany.

	<i>Metric</i>	<i>Imperial</i>
Krameria, in coarse powder .. .	50 g.	1 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of krameria should be used within twelve hours of its preparation.

When infusion of krameria (Infusum Krameriaë) is prescribed, fresh infusion not being specified, either Infusum Krameriaë Recens, or Infusum Krameriaë Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM LINI

(Inf. Lini)

Infusion of Linseed*Synonym*—Linseed Tea.

	<i>Metric</i>	<i>Imperial</i>
Linseed	34.3 g.	300 gr.
Liquorice, unpeeled, in coarse powder	11.4 g.	100 gr.
Distilled Water, boiling	1000.0 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 30 to 120 millilitres (1 to 4 fluid ounces).

For dispensing purposes, infusion of linseed should be used within twelve hours of its preparation.

INFUSUM LUPULI CONCENTRATUM

(Inf. Lupul. Conc.)

Concentrated Infusion of Lupulus

Synonym—Concentrated Infusion of Hops.

	<i>Metric</i>	<i>Imperial</i>
Lupulus, freshly broken	400 g.	8 oz.
Alcohol (25 per cent.)	1350 ml.	27 fl. oz.

Macerate the lupulus in 1000 millilitres (20 fluid ounces) of the alcohol in a covered vessel for forty-eight hours and press out the liquid. To the pressed marc add the remainder of the alcohol and macerate for twenty-four hours; press out the liquid, mix with the liquid previously obtained, allow to stand for not less than fourteen days, and filter.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

When infusion of lupulus (Infusum Lupuli) is prescribed, this concentrated infusion, diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM MARRUBII CONCENTRATUM

(Inf. Marrub. Conc.)

Concentrated Infusion of Horehound

	<i>Metric</i>	<i>Imperial</i>
Horehound, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	1400 ml.	28 fl. oz.

Macerate the horehound with 1000 millilitres (20 fluid ounces) of the alcohol in a covered vessel for forty-eight hours and press out the liquid; to the pressed marc add the remainder of the alcohol, macerate for twenty-four hours, press, add the liquid to the product of the first pressing, allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 22 per cent. v/v of ethyl alcohol.

When infusion of horehound (Infusum Marrubii) is prescribed, this concentrated infusion, diluted with seven times its volume of distilled water, may be dispensed

INFUSUM RHEI CONCENTRATUM**(Inf. Rhei Conc.)****Concentrated Infusion of Rhubarb**

	<i>Metric</i>	<i>Imperial</i>
Rhubarb, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the rhubarb with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected, evaporate to a syrupy consistence, dissolve the residue in the reserved portion, and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

INFUSUM RHEI RECENS**(Inf. Rhei Rec.)****Fresh Infusion of Rhubarb**

	<i>Metric</i>	<i>Imperial</i>
Rhubarb, in thin slices	50 g.	1 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of rhubarb should be used within twelve hours of its preparation.

When infusion of rhubarb (*Infusum Rhei*) is prescribed, fresh infusion not being specified, either *Infusum Rhei Recens*, or *Infusum Rhei Concentratum* diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM ROSÆ ACIDUM CONCENTRATUM**(Inf. Ros. Acid. Conc.)****Concentrated Acid Infusion of Roses**

	<i>Metric</i>	<i>Imperial</i>
Red-Rose Petal, dried and broken	200 g.	4 oz.
Dilute Sulphuric Acid	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Chloroform Water	950 ml.	19 fl. oz.

Macerate the red-rose petal in 700 millilitres (14 fluid ounces) of chloroform water for forty-eight hours and press out the liquid; to the

pressed marc add the remainder of the chloroform water, macerate for twenty-four hours, press, and add the liquid to the product of the first pressing. Heat the mixed liquids to boiling, cool, add the acid and the alcohol, allow to stand for not less than fourteen days, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 17 to 22 per cent. v/v of ethyl alcohol.

INFUSUM ROSÆ ACIDUM RECENS

(Inf. Ros. Acid. Rec.)

Fresh Acid Infusion of Roses

	<i>Metric</i>	<i>Imperial</i>
Red-Rose Petal, dried and broken	25.0 g.	$\frac{1}{2}$ oz.
Dilute Sulphuric Acid	12.5 ml.	120 m.
Distilled Water, boiling	1000.0 ml.	20 fl. oz.

Add the dilute sulphuric acid to the distilled water, infuse the red-rose petal in the mixture in a covered vessel for fifteen minutes, and strain.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh acid infusion of roses should be used within twelve hours of its preparation.

When acid infusion of roses (Infusum Rosæ Acidum) is prescribed, fresh infusion not being specified, either Infusum Rosæ Acidum Recens, or Infusum Rosæ Acidum Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM SCOPARII CONCENTRATUM

(Inf. Scopar. Conc.)

Concentrated Infusion of Scoparium

Synonym—Concentrated Infusion of Broom.

	<i>Metric</i>	<i>Imperial</i>
Scoparium, in moderately coarse powder	800 g.	16 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the scoparium with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected, evaporate to a syrupy consistence, dissolve the residue in the reserved portion and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 17 to 22 per cent. v/v of ethyl alcohol.

INFUSUM SCOPARII RECENS

(Inf. Scopar. Rec.)

Fresh Infusion of Scoparium*Synonym*—Fresh Infusion of Broom.

	<i>Metric</i>	<i>Imperial</i>
Scoparium, dried and bruised ..	100 g.	2 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.—30 to 60 millilitres (1 to 2 fluid ounces).

For dispensing purposes, fresh infusion of scoparium should be used within twelve hours of its preparation.

When infusion of scoparium (Infusum Scoparii) is prescribed, fresh infusion not being specified, either Infusum Scoparii Recens, or Infusum Scoparii Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM SERPENTARIÆ CONCENTRATUM

(Inf. Serpent. Conc.)

Concentrated Infusion of Serpentry

	<i>Metric</i>	<i>Imperial</i>
Serpentry, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the serpentry with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected; evaporate to a syrupy consistence, dissolve the residue in the reserved portion and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 19 to 22 per cent. v/v of ethyl alcohol.

When infusion of serpentry (Infusum Serpentariæ) is prescribed, this concentrated infusion, diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM UVÆ URSI CONCENTRATUM

(Inf. Uvæ Ursi Conc.)

Concentrated Infusion of Bearberry

	<i>Metric</i>	<i>Imperial</i>
Bearberry, in moderately coarse powder	400 g.	8 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the bearberry with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected; evaporate to a syrupy consistence, dissolve the residue in the reserved portion, and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 18 to 21 per cent. v/v of ethyl alcohol.

INFUSUM UVÆ URSI RECENS

(Inf. Uvæ Ursi Rec.)

Fresh Infusion of Bearberry

	<i>Metric</i>	<i>Imperial</i>
Bearberry, bruised	50 g.	1 oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of bearberry should be used within twelve hours of its preparation.

When infusion of bearberry (Infusum Uvæ Ursi) is prescribed, fresh infusion not being specified, either Infusum Uvæ Ursi Recens, or Infusum Uvæ Ursi Concentratum diluted with seven times its volume of distilled water, may be dispensed.

INFUSUM VALERIANÆ CONCENTRATUM

(Inf. Valerian. Conc.)

Concentrated Infusion of Valerian

	<i>Metric</i>	<i>Imperial</i>
Valerian, in moderately coarse powder	200 g.	4 oz.
Alcohol (25 per cent.)	to 1000 ml.	to 20 fl. oz.

Extract the valerian with the alcohol by percolation, reserving the first 750 millilitres (15 fluid ounces) of percolate. Continue percolation until a further 1000 millilitres (20 fluid ounces) has been collected; evaporate to a syrupy consistence, dissolve the residue in the reserved portion, and add, if necessary, sufficient of the alcohol to produce the required volume. Allow to stand for not less than fourteen days, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 20 to 23 per cent. v/v of ethyl alcohol.

INFUSUM VALERIANÆ RECENS

(Inf. Valerian. Rec.)

Fresh Infusion of Valerian

	<i>Metric</i>	<i>Imperial</i>
Valerian, bruised.	25 g.	$\frac{1}{2}$ oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse in a covered vessel for fifteen minutes, and strain.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

For dispensing purposes, fresh infusion of valerian should be used within twelve hours of its preparation.

When infusion of valerian (*Infusum Valerianæ*) is prescribed, fresh infusion not being specified, either *Infusum Valerianæ Recens*, or *Infusum Valerianæ Concentratum* diluted with seven times its volume of distilled water, may be dispensed.

INJECTIONES**Injections**

Injections may be divided into two main classes, those intended for introduction through the skin, and those which are passed directly through the external orifices of the body. The former class may be subdivided into the following groups of injections:—(1) Intradermal; (2) Hypodermic or Subcutaneous; (3) Intramuscular; (4) Intravenous; (5) Intraspinal, intrathecal, or intracisternal. Injections coming within these five groups must be sterile, and in addition, when intended for intravenous use, they should usually be rendered isotonic with blood serum. Whenever possible, solutions or suspensions intended for injection through the skin should be dispensed in ampoules. Special processes to be used in preparing and sterilising solutions for injection, and methods for sterilising vessels and containers, are described in Appendix XII. Tests for the alkalinity of glass and tests for sterility are described in the British Pharmacopœia. All sera and vaccines should be stored in a dark, cool place, preferably in an ice-safe or refrigerator.

Intradermal Injections are given between the layers of the skin, and this method is used for applying skin tests for specific immunity, and for obtaining reactions for the diagnosis of protein sensitivity. Certain vaccines may be administered intradermally.

Hypodermic or Subcutaneous Injections are usually aqueous solutions. The concentration of a hypodermic or subdermal injection is adjusted usually so that the volume injected is small, varying from 0.2 to 1 millilitre (3 to 15 minims). Etheral or oily solutions and suspensions of potent drugs, anæsthetics, or vaccines may also be given in this way. Deep injections of large volume may be administered by gravitational methods into the deeper folds of the skin.

Intramuscular Injections may be sera, solutions or suspensions in sterilised water, or aqueous or oily suspensions of certain metals or their salts in a state of fine subdivision.

Intravenous Injections should be carefully filtered free from solid particles. The quantities administered into the blood stream may be small, 1 to 5 millilitres (15 to 75 minims) if potent solutions are given, or large, from 150 to 900 millilitres (5 to 30 fluid ounces) if isotonic solutions are given. Certain sera may be given intravenously.

Intraspinal or Intrathecal Injections are usually solutions for the production of varying degrees of anæsthesia, and may contain substances to increase the specific gravity of the liquid to enable its action to be localised. Sera are given intrathecally, intraspinally, or intracisternally for certain specific diseases.

Preparations for injection into cavities of the body may be subdivided into the following groups:—(1) Nasal; (2) Aural; (3) Rectal; (4) Urethral; (5) Vaginal. These preparations are frequently termed lotions and are used for irrigation and other purposes. They should be dispensed in bottles distinguishable from those used for preparations intended for oral administration.

Nasal Injections are usually solutions of antiseptics in oil or water, and are administered by means of a rubber or glass syringe, or by spray-producing apparatus.

Aural Injections are usually aqueous lotions which are administered by means of a syringe. 300 to 600 millilitres (10 to 20 fluid ounces) may be used as a wash.

Rectal Injections are described under Enemata.

Urethral Injections are usually antiseptic or astringent solutions or suspensions. The quantities usually injected are 8 to 16 millilitres (2 to 4 fluid drachms). The urethral route is used for bladder injections or for the introduction into the bladder or the pelvis of the kidney of certain shadow-producing solutions for X-ray diagnosis. Warm lotions and suspensions are used as bladder injections. These should be sterile.

Vaginal Injections are usually concentrated solutions which are diluted to a suitable strength immediately before use. They are usually sedative, antiseptic, or astringent, and 600 to 1200 millilitres (20 to 40 fluid ounces) is used at a time.

Isotonic Solutions.—To make a solution of any one of the following substances so that it is isotonic with blood serum, the quantity given below should be dissolved in sufficient water to produce 100 millilitres (4 fluid ounces):—

Borax	2.90 grammes	(50 $\frac{3}{4}$ grains)
Calcium Chloride	1.18 grammes	(20 $\frac{1}{2}$ grains)
Dextrose	5.10 grammes	(89 $\frac{1}{4}$ grains)
Magnesium Sulphate	6.35 grammes	(111 grains)
Potassium Sulphate	1.12 grammes	(19 $\frac{1}{2}$ grains)
Sodium Bicarbonate	1.35 grammes	(23 $\frac{1}{2}$ grains)
Sodium Bromide	1.77 grammes	(31 grains)
Sodium Chloride	0.91 gramme	(16 grains)
Sodium Phosphate	4.53 grammes	(79 $\frac{1}{4}$ grains)

If an aqueous solution of a medicament is required to be rendered isotonic with blood serum by the addition of another substance, the amount to be added, *W*, may be calculated approximately from the formula

$$W = \frac{0.56 - a}{b} \text{ per cent. w/v,}$$

where *a* denotes the freezing-point of the unadjusted solution in degrees below 0° and *b* denotes the depression of the freezing-point of water produced by 1 per cent. w/v of the adjusting substance.

The following table gives the depression of the freezing-point of water produced by 1 per cent. w/v of a number of substances commonly required in injections or suitable for adding to injections in order to render them isotonic, and the figures in the table, therefore, are the values of *b* for use in the above formula. The value of *a* for any prescribed strength of a substance may be found by multiplying the strength expressed as a percentage w/v by the value of *b* for the same substance.

Alum	0.10
Atropine Sulphate ..	0.074
Borax	0.22
Boric Acid	0.25
Cocaine Hydrochloride ..	0.12
Dextrose	0.10
Emetine Hydrochloride ..	0.088
Magnesium Sulphate ..	0.08
Morphine Hydrochloride ..	0.096
Procaine Hydrochloride ..	0.14
Silver Nitrate	0.20
Sodium Benzoate	0.31
Sodium Bicarbonate	0.40
Sodium Chloride	0.585
Sodium Nitrate	0.40
Sodium Sulphate	0.15
Sucrose	0.054

INJECTIO CAMPHORÆ

(Inj. Camph.)

Injection of Camphor

	<i>Metric</i>	<i>Imperial</i>
Camphor	10 g.	175 gr.
Olive Oil	to 100 ml.	to 4 fl. oz.

Heat about 100 millilitres (4 fluid ounces) of olive oil at 150° for one hour, and cool. Dissolve the camphor in a portion of the oil, and add sufficient of the oil to produce the required volume; transfer to suitable sterilised containers, and sterilise by heating at 100° for thirty minutes, by heating in an autoclave, or by tyndallisation.

Dose.—0.5 to 2 millilitres (8 to 30 minims), by subcutaneous injection.

INJECTIO CAMPHORÆ ÆTHEREA

(Inj. Camph. Æther.)

Ethereal Injection of Camphor*Synonym*—Curschmann's Solution.

	<i>Metric</i>	<i>Imperial</i>
Camphor	20 g.	350 gr.
Ether	30 ml.	1 fl. oz. 96 m.
Olive Oil	to 100 ml.	to 4 fl. oz.

Heat about 100 millilitres (4 fluid ounces) of olive oil at 150° for one hour, and cool. Dissolve the camphor in a portion of the oil, and add sufficient of the oil to produce 70 millilitres (2 fluid ounces 384 minims); sterilise by heating at 100° for thirty minutes in a closed vessel, by heating in an autoclave, or by tyndallisation, add the ether, and mix.

Dose.—0.25 to 1 millilitre (4 to 15 minims), by subcutaneous injection.

INJECTIO DIGITALINI

(Inj. Digitalin.)

Injection of Digitalin

	<i>Metric</i>	<i>Imperial</i>
Digitalin	3 g.	52½ gr.
Distilled Water	to 100 ml.	to 4 fl. oz.

Dissolve. Sterilise by tyndallisation or by filtration. It should be recently prepared and **stored** protected from light.

Dose.—For a single administration, 1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm), by subcutaneous injection; for repeated administration, 0.2 to 0.4 millilitre (3 to 6 minims), by subcutaneous injection.

INJECTIO FERRI ET ARSENI

(Inj. Ferr. et Arsen.)

Injection of Iron and Arsenic

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ferric Chloride	1.75 ml.	33½ m.
Citric Acid	2.00 g.	35 gr.
Arsenic Trioxide	0.13 g.	2¼ gr.
Dilute Solution of Ammonia	a sufficient quantity	
Sterilised Water	to 100.0 ml.	to 4 fl. oz.

Mix the strong solution of ferric chloride with 40 millilitres (1½ fluid ounces) of distilled water and add the mixture, very gradually, with constant stirring, to a mixture of 6 millilitres (120 minims) of dilute solution of ammonia and 25 millilitres (1 fluid ounce) of distilled water; allow to stand for two hours, stirring every quarter of an hour; filter, using slight suction, and wash the precipitate with distilled water until

completely free from chloride. Suspend the precipitate in 20 millilitres (384 minims) of sterilised water and add the suspension to a hot solution of the citric acid in 5 millilitres (96 minims) of sterilised water, adding a small portion at first and allowing it to dissolve before adding the bulk of the suspension. Maintain the mixture at a temperature just below the boiling-point for forty-five minutes, then add a further 20 millilitres (384 minims) of sterilised water and the arsenic trioxide dissolved with the aid of gentle heat in a mixture of 15 millilitres (288 minims) of sterilised water and 1 millilitre (20 minims) of dilute solution of ammonia. Finally add 1.5 millilitres (30 minims) of dilute solution of ammonia or sufficient to give a reaction not acid to methyl red and not alkaline to phenol red, and sufficient sterilised water to produce the required volume. Sterilise by heating in an autoclave or by tyndallisation.

It should be **stored** protected from light.

Dose.—0.5 to 1 millilitre (8 to 15 minims), by intramuscular injection.

INJECTIO HYDRARGYRI FORTIS

(Inj. Hydrarg. Fort.)

Strong Injection of Mercury

Synonyms—Oleum Cinereum; Grey Oil.

	<i>Metric</i>	<i>Imperial</i>
Mercury	40 g.	2 oz.
Wool Fat	26 g.	1 oz. 131¼ gr.
Liquid Paraffin	70 ml.	3½ fl. oz.

Heat the wool fat and the liquid paraffin separately at 150° for one hour; triturate the mercury and the wool fat in a sterilised mortar until metallic globules cease to be visible under a lens magnifying four diameters, and gradually add the liquid paraffin with constant trituration.

Dose.—0.06 to 0.12 millilitre (1 to 2 minims), by intramuscular injection.

INJECTIO MORPHINÆ

(Inj. Morph.)

Injection of Morphine

	<i>Metric</i>	<i>Imperial</i>
Morphine Hydrochloride ..	2.5 g.	43¼ gr.
Sterilised Water to 100.0 ml.	to 4 fl. oz.

Dissolve, and sterilise by heating in an autoclave, by tyndallisation, or filtration.

Dose.—0.2 to 0.6 millilitre (3 to 10 minims), by subcutaneous injection.

INJECTIO PEPTONI

(Inj. Pepton.)

Injection of Peptone

	<i>Metric</i>	<i>Imperial</i>
Peptone	5.0 g.	87½ gr.
Sodium Chloride	0.9 g.	15¾ gr.
Sodium Hydroxide	a sufficient	quantity
Phenol	0.5 g.	8¾ gr.
Sterilised Water for Intravenous		
Injections to 100.0 ml.	to 4 fl. oz.

Dissolve the peptone and the sodium chloride in about 90 millilitres (3½ fluid ounces) of the sterilised water with the aid of heat. Add to the solution a 1 per cent. w/v solution of sodium hydroxide in the sterilised water until the liquid is neutral to litmus or to phenol red; dissolve the phenol in the product, filter, and pass sufficient of the sterilised water through the filter to produce the required volume; sterilise by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.2 millilitre (3 minims) gradually increased to 1.5 millilitres (25 minims), by intravenous injection.

When Injectio Peptoni is required for intramuscular injection, it should be prepared with 7.5 grammes (131¼ grains) of peptone.

INJECTIO QUININÆ ET URETHANI

(Inj. Quinin. et Urethan.)

Injection of Quinine and Urethane

	<i>Metric</i>	<i>Imperial</i>
Quinine Hydrochloride	13.33 g.	232¾ gr.
Urethane	6.67 g.	116¼ gr.
Sterilised Water for Intravenous		
Injections to 100.00 ml.	to 4 fl. oz.

Dissolve, and sterilise by heating in an autoclave, by tyndallisation, or by filtration.

Dose.—0.5 to 5 millilitres (8 to 75 minims), by intravenous injection.

INJECTIO SODII MORRHUATIS

(Inj. Sod. Morrh.)

Injection of Sodium Morrhuate

	<i>Metric</i>	<i>Imperial</i>
Sodium Morrhuate	5 g.	87½ gr.
Alcohol (90 per cent.)	1 ml.	19 m.
Sterilised Water for Intravenous		
Injections to 100 ml.	to 4 fl. oz.

Dissolve, and sterilise by heating in an autoclave, by tyndallisation, or by filtration.

Dose.— 0·5 to 5 millilitres (8 to 75 minims), by intravenous injection.

When solid matter separates, it should be redissolved by warming, and the injection should be used with a syringe, previously warmed.

INJECTIO STRYCHNINÆ

(Inj. Strych.)

Injection of Strychnine

	<i>Metric</i>	<i>Imperial</i>
Strychnine Hydrochloride	0·75 g.	13½ gr.
Sterilised Water to 100·00 ml.	to 4 fl. oz.

Dissolve, and sterilise by heating in an autoclave, by tyndallisation, or by filtration.

Dose.— 0·3 to 0·6 millilitre (5 to 10 minims), by subcutaneous injection.

INJECTIO THIOSINAMINÆ ET SODII SALICYLATIS

(Inj. Thiosinam. et Sod. Salicyl.)

Injection of Thiosinamine and Sodium Salicylate

	<i>Metric</i>	<i>Imperial</i>
Thiosinamine	10·0 g.	175 gr.
Sodium Salicylate	13·8 g.	241½ gr.
Glycerin	5·0 ml.	96 m.
Sterilised Water to 100·0 ml.	to 4 fl. oz.

Dissolve the sodium salicylate in about 80 millilitres (3½ fluid ounces) of sterilised water and add the glycerin; dissolve the thiosinamine in the solution and add sufficient sterilised water to produce the required volume. Sterilise by tyndallisation or by filtration.

It should be recently prepared.

Dose.— 0·5 to 1 millilitre (8 to 15 minims), by subcutaneous or intramuscular injection.

INSUFFLATIONES

Insufflations

Insufflations are powders prepared for introduction into the ear, nose, or throat. They are administered by means of an insufflator or, when intended for the nose, they may be used in the same way as ordinary snuff.

INSUFFLATIO ADRENALINÆ

(Insuff. Adrenal.)

Adrenaline Insufflation*Synonym*—Adrenaline Snuff.

			<i>Metric</i>	<i>Imperial</i>
Adrenaline	0.1 g.	1 gr.
Boric Acid	24.0 g.	240 gr.
Camphor	2.0 g.	20 gr.
Menthol	6.0 g.	60 gr.
Oil of Eucalyptus	1.0 ml.	11 m.
Potassium Chlorate	12.0 g.	120 gr.
Lycopodium	87.5 g.	2 oz.

Reduce the adrenaline, boric acid, camphor and menthol to fine powder, add the potassium chlorate previously powdered, and mix with the oil of eucalyptus and lycopodium.

It should be **stored** in well-closed containers in a cool place.

INSUFFLATIO BISMUTHI ET MORPHINÆ

(Insuff. Bism. et Morph.)

Bismuth and Morphine Insufflation*Synonyms*—Ferrier's Snuff; Bismuth and Morphine Snuff.

			<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate	75.0 g.	3 oz.
Morphine Hydrochloride	0.4 g.	7½ gr.
Acacia, in powder	to 100.0 g.	to 4 oz.

Mix.

INSUFFLATIO MENTHOLIS

(Insuff. Menthol.)

Menthol Insufflation*Synonyms*—Insufflatio Mentholis Composita; Menthol Snuff.

			<i>Metric</i>	<i>Imperial</i>
Menthol	5 g.	87½ gr.
Ammonium Chloride	10 g.	175 gr.
Boric Acid	20 g.	350 gr.
Lycopodium	to 100 g.	to 4 oz.

Reduce the menthol, ammonium chloride and boric acid to fine powder and mix with sufficient lycopodium to produce the required weight.

INSUFFLATIO MENTHOLIS ET COCAINÆ**(Insuff. Menthol. et Cocain.)****Menthol and Cocaine Insufflation***Synonym*—Menthol and Cocaine Snuff.

	<i>Metric</i>	<i>Imperial</i>
Menthol	2.5 g.	43 $\frac{3}{4}$ gr.
Cocaine Hydrochloride	0.14 g.	2 $\frac{1}{2}$ gr.
Ammonium Chloride	25.0 g.	1 oz.
Camphor	5.0 g.	87 $\frac{1}{2}$ gr.
Lycopodium	to 100.0 g.	to 4 oz.

Reduce the menthol, cocaine hydrochloride, ammonium chloride and camphor to fine powder and mix with sufficient lycopodium to produce the required weight.

LINCTI**Linctuses**

Linctuses are liquid preparations of a mucilaginous, syrupy, or viscous nature containing substances which possess demulcent, expectorant, or sedative properties. They are usually administered in small doses and should be directed to be sipped and swallowed slowly without the addition of water, so that they may form a temporary protective or remedial film over the membrane of the throat.

LINCTUS ACIDUS**(Linct. Acid.)****Acid Linctus**

	<i>Metric</i>	<i>Imperial</i>
Oxymel	333.3 ml.	6 fl. oz. 320 m.
Dilute Sulphuric Acid	83.3 ml.	1 fl. oz. 320 m.
Emulsion of Chloroform	33.3 ml.	320 m.
Treacle	to 1000.0 ml.	to 20 fl. oz.

Mix the dilute sulphuric acid and the emulsion of chloroform with the oxymel and add sufficient treacle to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS CAMPHORÆ COMPOSITUS

(Linct. Camph. Co.)

Compound Linctus of Camphor

	<i>Metric</i>	<i>Imperial</i>
Camphorated Tincture of Opium	250.0 ml.	5 fl. oz.
Emulsion of Chloroform ..	125.0 ml.	2½ fl. oz.
Syrup of Wild Cherry	200.0 ml.	4 fl. oz.
Oxymel of Squill.	200.0 ml.	4 fl. oz.
Solution of Bordeaux B ..	10.4 ml.	100 m.
Concentrated Infusion of Senega	to 1000.0 ml.	to 20 fl. oz.

Mix, allow to stand for not less than two days, and filter, using purified talc or kaolin if necessary.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

LINCTUS CODEINÆ

(Linct. Codein.)

Linctus of Codeine

	<i>Metric</i>	<i>Imperial</i>
Syrup of Codeine Phosphate ..	500.0 ml.	10 fl. oz.
Citric Acid	17.5 g.	153 gr.
Emulsion of Chloroform ..	50.0 ml.	1 fl. oz.
Glycerin	165.0 ml.	3 fl. oz. 144 m.
Mucilage of Tragacanth ..	to 1000.0 ml.	to 20 fl. oz.

Dissolve the citric acid in the syrup of codeine phosphate and add the glycerin, emulsion of chloroform, and sufficient mucilage of tragacanth to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS DIAMORPHINÆ

(Linct. Diamorph.)

Linctus of Diamorphine

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	1 g.	8¾ gr.
Tincture of Hyoscyamus ..	75 ml.	1½ fl. oz.
Spirit of Chloroform	75 ml.	1½ fl. oz.
Syrup of Tolu	150 ml.	3 fl. oz.
Syrup of Wild Cherry	150 ml.	3 fl. oz.
Glycerin to 1000 ml.	to 20 fl. oz.

Mix the tincture of hyoscyamus with the spirit of chloroform and dissolve the diamorphine hydrochloride in the mixture; add the syrup of tolu, the syrup of wild cherry and sufficient glycerin to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{3}$ to 2 fluid drachms).

LINCTUS DIAMORPHINÆ CAMPHORATUS

(*Linct. Diamorph. Camph.*)

Camphorated Linctus of Diamorphine

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0.46 g.	4 gr.
Camphor	0.46 g.	4 gr.
Benzoic Acid	0.69 g.	6 gr.
Oil of Anise	0.52 ml.	5 m.
Liquid Extract of Ipecacuanha ..	12.5 ml.	120 m.
Tincture of Squill	75.0 ml.	1½ fl. oz.
Syrup	to 1000.0 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride, camphor, benzoic acid and oil of anise in the tincture of squill; add the liquid extract of ipecacuanha and sufficient syrup to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS DIAMORPHINÆ CUM IPECACUANHA

(*Linct. Diamorph. c. Ipecac.*)

Linctus of Diamorphine with Ipecacuanha

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0.46 g.	4 gr.
Liquid Extract of Ipecacuanha ..	12.5 ml.	120 m.
Tincture of Hyoscyamus	75.0 ml.	1½ fl. oz.
Spirit of Chloroform	75.0 ml.	1½ fl. oz.
Syrup of Tolu	150.0 ml.	3 fl. oz.
Syrup of Wild Cherry	150.0 ml.	3 fl. oz.
Glycerin	to 1000.0 ml.	to 20 fl. oz.

Mix the tincture of hyoscyamus with the spirit of chloroform and dissolve the diamorphine hydrochloride in the mixture; add the liquid extract of ipecacuanha, syrup of tolu, syrup of wild cherry and sufficient glycerin to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS DIAMORPHINÆ ET SCILLÆ

(Linct. Diamorph. et Scill.)

Linctus of Diamorphine and Squill

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0.46 g.	4 gr.
Sodium Antimonyltartrate ..	0.91 g.	8 gr.
Liquid Extract of Squill ..	50.0 ml.	1 fl. oz.
Liquid Extract of Senega ..	50.0 ml.	1 fl. oz.
Glycerin	100.0 ml.	2 fl. oz.
Syrupto 1000.0 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride and the sodium antimonyltartrate in a portion of the syrup; add the liquid extract of squill, liquid extract of senega, glycerin and sufficient syrup to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS DIAMORPHINÆ ET THYMI

(Linct. Diamorph. et Thym.)

Linctus of Diamorphine and Thyme

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0.46 g.	4 gr.
Apomorphine Hydrochloride ..	0.57 g.	5 gr.
Distilled Water	50.0 ml.	1 fl. oz.
Liquid Extract of Thyme ..	250.0 ml.	5 fl. oz.
Solution of Tolu	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Glycerinto 1000.0 ml.	to 20 fl. oz.

Dissolve the diamorphine hydrochloride and the apomorphine hydrochloride in the distilled water; add the liquid extract of thyme, the solution of tolu and sufficient glycerin to produce the required volume

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LINCTUS SCILLÆ

(Linct. Scill.)

Linctus of Squill*Synonyms*—Linctus; Simple Linctus.

		<i>Metric</i>	<i>Imperial</i>
Oxymel of Squill	250 ml.	5 fl. oz.
Mucilage of Tragacanth	250 ml.	5 fl. oz.
Glycerin	250 ml.	5 fl. oz.
Emulsion of Chloroform	50 ml.	1 fl. oz.
Syrup to 1000 ml.	to 20 fl. oz.
Mix.			

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**LINCTUS SCILLÆ COMPOSITUS**

(Linct. Scill. Co.)

Compound Linctus of Squill*Synonyms*—Linctus Scillæ Opiatus; Opiate Linctus of Squill; Gee's Linctus.

		<i>Metric</i>	<i>Imperial</i>
Camphorated Tincture of Opium		250 ml.	5 fl. oz.
Oxymel of Squill	250 ml.	5 fl. oz.
Syrup of Tolu	250 ml.	5 fl. oz.
Mix.			

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**LINIMENTA****Liniments**

Liniments are usually liquid or semi-liquid preparations which are intended for external application and may contain substances possessing anodyne, rubefacient, sedative, or stimulating properties. Anodyne and sedative liniments are intended to be absorbed by the skin, and should be prepared with a spirituous medium or with a mixture of volatile and fixed oils. They may be directed to be applied to the skin on warmed flannel or other suitable material, or by means of a camel-hair brush. They should not be applied to broken surfaces. Stimulating liniments should be applied to the skin with considerable friction by massaging with the hand. These also should only be applied to unbroken surfaces. Liniments intended as soothing or protective coverings may be applied freely on any soft material such as lint, and may be renewed frequently.

All liniments should be dispensed in containers easily distinguishable by touch from those used for medicines intended for internal administration and, in addition to any prescribed directions, the container should always be labelled "Not to be taken internally."

LINIMENTUM ACONITI OLEOSUM

(Lin. Aconit. Oleos.)

Liniment of Aconite with Oil

Synonym—A.B.C. Liniment.

		<i>Metric</i>	<i>Imperial</i>
Liniment of Aconite	500 ml.	10 fl. oz.
Liniment of Belladonna	500 ml.	10 fl. oz.
Liniment of Chloroform	500 ml.	10 fl. oz.

Shake together. (This liniment must be well shaken before use.)

The non-oily liniment of the British Pharmaceutical Codex, 1923, is included under the name of *Pigmentum Aconiti Compositum*.

LINIMENTUM ALBUM

(Lin. Alb.)

White Liniment

Synonyms—Egg Liniment; White Embrocation; *Linimentum Album Aceticum*.

			<i>Metric</i>	<i>Imperial</i>
Acetic Acid	85 ml.	1 fl. oz.	336 m.
Oil of Turpentine	400 ml.	8 fl. oz.	
Yolk and White of Egg	100 ml.	2 fl. oz.	
Distilled Water	415 ml.	8 fl. oz.	144 m.

Triturate the yolk and white of egg in a mortar and gradually add the acetic acid diluted with about 200 millilitres (4 fluid ounces) of the water. Add the remainder of the water, strain through muslin into a suitable bottle, add the oil of turpentine, and shake for five minutes.

LINIMENTUM AMMONIÆ

(Lin. Ammon.)

Liniment of Ammonia

			<i>Metric</i>	<i>Imperial</i>
Dilute Solution of Ammonia	250 ml.	5 fl. oz.	
Oleic Acid	25 ml.	$\frac{1}{2}$ fl. oz.	
Liquid Paraffin	725 ml.	14 $\frac{1}{2}$ fl. oz.	

Mix the oleic acid with the liquid paraffin, add the dilute solution of ammonia, and shake.

LINIMENTUM ARNICÆ

(Lin. Arnic.)

Liniment of Arnica*Synonym*—Arnica Opodeldoc.

	<i>Metric</i>	<i>Imperial</i>
Hard Soap	200 g.	4 oz.
Tincture of Arnica Root	250 ml.	5 fl. oz.
Camphor	50 g.	1 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve the hard soap in a mixture of the tincture of arnica root and 500 millilitres (10 fluid ounces) of the alcohol on a water-bath, dissolve the camphor in the solution and add sufficient of the alcohol to produce the required volume; pour into suitable bottles and allow to solidify.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, and the tincture of arnica root may be replaced by tincture of arnica root prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM BELLADONNÆ CUM CHLOROFORMO

(Lin. Bellad. c. Chlorof.)

Liniment of Belladonna with Chloroform

	<i>Metric</i>	<i>Imperial</i>
Chloroform	125 ml.	2½ fl. oz.
Liniment of Belladonna	to 1000 ml.	to 20 fl. oz.

Mix.

LINIMENTUM CALAMINÆ

(Lin. Calamin.)

Liniment of Calamine

	<i>Metric</i>	<i>Imperial</i>
Calamine	45·7 g.	400 gr.
Zinc Oxide	34·3 g.	300 gr.
Oleic Acid	5·0 ml.	48 m.
Wool Fat	10·0 g.	87½ gr.
Liquid Paraffin	485·0 ml.	9 fl. oz. 336 m.
Solution of Calcium Hydroxide	500·0 ml.	10 fl. oz.

Melt the wool fat in the liquid paraffin with the aid of gentle heat and add the oleic acid. Gradually add this mixture, with constant trituration, to the calamine and zinc oxide previously mixed with the solution of calcium hydroxide.

LINIMENTUM CALAMINÆ COMPOSITUM

(Lin. Calamin. Co.)

Compound Liniment of Calamine

	<i>Metric</i>	<i>Imperial</i>
Calamine	100 g.	2 oz.
Zinc Oxide	50 g.	1 oz.
Zinc Oleostearate	25 g.	$\frac{1}{2}$ oz.
Wool Fat	25 g.	$\frac{1}{2}$ oz.
White Soft Paraffin	200 g.	4 oz.
Liquid Paraffin to 1000 ml.		to 20 fl. oz.

Triturate the calamine and zinc oxide to a smooth paste with a portion of the liquid paraffin. Melt together the zinc oleostearate, wool fat and soft paraffin at a low temperature and mix with more of the liquid paraffin; incorporate this mixture with the calamine and zinc oxide paste, and add sufficient liquid paraffin to produce the required volume.

LINIMENTUM CALCII HYDROXIDI

(Lin. Calc. Hydrox.)

Liniment of Calcium Hydroxide*Synonyms*—Linimentum Calcis; Liniment of Lime.

	<i>Metric</i>	<i>Imperial</i>
Olive Oil	500 ml.	10 fl. oz.
Solution of Calcium Hydroxide ..	500 ml.	10 fl. oz.

Shake together.

LINIMENTUM CALCII HYDROXIDI CUM OLEO LINI

(Lin. Calc. Hydrox. c. Ol. Lini)

Liniment of Calcium Hydroxide with Linseed Oil*Synonyms*—Lime Water and Oil; Carron Oil; Linimentum Calcis cum Oleo Lini.

	<i>Metric</i>	<i>Imperial</i>
Linseed Oil	500 ml.	10 fl. oz.
Solution of Calcium Hydroxide	500 ml.	10 fl. oz.

Shake together.

LINIMENTUM CAPSICI

(Lin. Capsic.)

Liniment of Capsicum

	<i>Metric</i>	<i>Imperial</i>
Stronger Tincture of Capsicum	350.0 ml.	7 fl. oz.
Oleic Acid	125.0 ml.	2½ fl. oz.
Oil of Lavender	6.2 ml.	60 m.
Alcohol (90 per cent.) to 1000.0 ml.		to 20 fl. oz.

Mix the stronger tincture of capsicum with 500 millilitres (10 fluid ounces) of the alcohol, add the oleic acid, the oil of lavender, and sufficient of the alcohol to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, and the stronger tincture of capsicum may be replaced by stronger tincture of capsicum prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM CHLOROFORMI

(Lin. Chlorof.)

Liniment of Chloroform

	<i>Metric</i>	<i>Imperial</i>
Chloroform	500 ml.	10 fl. oz.
Liniment of Camphor	500 ml.	10 fl. oz.

Mix.

LINIMENTUM CROTONIS

(Lin. Croton.)

Liniment of Croton Oil

	<i>Metric</i>	<i>Imperial</i>
Croton Oil	120 ml.	3 fl. oz.
Oil of Cajuput	440 ml.	11 fl. oz.
Alcohol (90 per cent.)	440 ml.	11 fl. oz.

Mix.

In making this liniment the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM HYDRARGYRI

(Lin. Hydrarg.)

Liniment of Mercury

	<i>Metric</i>	<i>Imperial</i>
Ointment of Mercury	300 g.	5 oz.
Dilute Solution of Ammonia ..	240 ml.	4 fl. oz.
Liniment of Camphor	480 ml.	8 fl. oz.

Shake the dilute solution of ammonia with the liniment of camphor and triturate the ointment of mercury with the mixture.

LINIMENTUM METHYLIS SALICYLATIS

(Lin. Methyl. Salicyl.)

Liniment of Methyl Salicylate

Synonyms—Linimentum Betulæ Compositum; Compound Liniment of Birch.

	<i>Metric</i>	<i>Imperial</i>
Menthol	50 g.	1 oz.
Oil of Eucalyptus	100 ml.	2 fl. oz.
Rectified Oil of Camphor ..	250 ml.	5 fl. oz.
Methyl Salicylate	to 1000 ml.	to 20 fl. oz.

Dissolve the menthol in the oil of eucalyptus, rectified oil of camphor and about 500 millilitres (10 fluid ounces) of the methyl salicylate, and add sufficient methyl salicylate to produce the required volume.

LINIMENTUM METHYLIS SALICYLATIS COMPOSITUM

(Lin. Methyl. Salicyl. Co.)

Compound Liniment of Methyl Salicylate

	<i>Metric</i>	<i>Imperial</i>
Menthol	50.0 g.	1 oz.
Chloral Hydrate	50.0 g.	1 oz.
Chlorophyll	0.5 g.	4½ gr.
Rectified Oil of Camphor ..	250.0 ml.	5 fl. oz.
Methyl Salicylate	to 1000.0 ml.	to 20 fl. oz.

Dissolve the menthol, chloral hydrate and chlorophyll in the rectified oil of camphor and about 500 millilitres (10 fluid ounces) of the methyl salicylate, and add sufficient methyl salicylate to produce the required volume.

LINIMENTUM METHYLIS SALICYLATIS OLEOSUM

(Lin. Methyl. Salicyl. Oleos.)

Liniment of Methyl Salicylate with Oil*Synonym*—Linimentum Methylis Salicylatis Simplex.

			<i>Metric</i>	<i>Imperial</i>
Methyl Salicylate	250 ml.	5 fl. oz.
Rape Oil	to 1000 ml.	to 20 fl. oz.
Mix.				

LINIMENTUM OPII

(Lin. Opii)

Liniment of Opium

			<i>Metric</i>	<i>Imperial</i>
Tincture of Opium	500 ml.	10 fl. oz.
Liniment of Soap	500 ml.	10 fl. oz.

Mix, set aside for a few days, and filter.

In making this preparation the tincture of opium may be replaced by tincture of opium prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM POTASSII IODIDI

(Lin. Pot. Iod.)

Liniment of Potassium Iodide

			<i>Metric</i>	<i>Imperial</i>
Soft Soap	135 g.	2 oz. 306½ gr.
Potassium Iodide	100 g.	2 oz.
Glycerin	70 ml.	1 fl. oz. 192 m.
Oil of Lemon	10 ml.	96 m.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the glycerin with 600 millilitres (12 fluid ounces) of the alcohol, dissolve the soap in the mixture, add the oil of lemon and the potassium iodide, previously powdered, and shake until solution is effected, then add sufficient of the alcohol to produce the required volume. Allow to stand for a few hours, and decant or filter if necessary.

In making this liniment the alcohol (60 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM POTASSII IODIDI CUM SAPONE

(*Lin. Pot. Iod. c. Sap.*)

Liniment of Potassium Iodide with Soap

	<i>Metric</i>	<i>Imperial</i>
Curd Soap, recently prepared and in shavings	160 g.	2 oz.
Potassium Iodide	120 g.	1½ oz.
Glycerin	80 ml.	1 fl. oz.
Oil of Lemon	8 ml.	48 m.
Distilled Water	800 ml.	10 fl. oz.

Mix the curd soap with the distilled water and the glycerin in a tared porcelain dish on a water-bath; when the soap is dissolved make up to the original weight with distilled water; pour the liquid into a mortar containing the potassium iodide, previously powdered, and mix briskly by trituration until the mixture is cold; set aside for one hour, add the oil of lemon, and again triturate the gelatinous product.

LINIMENTUM SAPONIS CAMPHORATUM

(*Lin. Sap. Camph.*)

Camphorated Soap Liniment

Synonym—Solid Opodeldoc.

	<i>Metric</i>	<i>Imperial</i>
Curd Soap, in shavings	80 g.	1 oz.
Camphor, in flowers	20 g.	¾ oz.
Oil of Thyme	4 g.	22 gr.
Oil of Rosemary	6 g.	33 gr.
Dilute Solution of Ammonia	50 g.	273½ gr.
Alcohol (90 per cent.)	840 g.	10½ oz.

Dissolve the curd soap and camphor in the alcohol with the aid of gentle heat; filter while warm, add the oils and the dilute solution of ammonia, mix thoroughly, pour into suitable containers, and allow to solidify.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM SINAPIS**(Lin. Sinap.)****Liniment of Mustard**

	<i>Metric</i>	<i>Imperial</i>
Volatile Oil of Mustard	35 ml.	336 m.
Camphor	55 g.	481½ gr.
Castor Oil	125 ml.	2½ fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve the camphor and the oils in sufficient of the alcohol to produce the required volume.

In making this liniment the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LINIMENTUM SUCCINI COMPOSITUM**(Lin. Succin. Co.)****Compound Liniment of Amber**

	<i>Metric</i>	<i>Imperial</i>
Oil of Amber	250 ml.	5 fl. oz.
Oil of Clove	250 ml.	5 fl. oz.
Olive Oil	500 ml.	10 fl. oz.
Mix.		

LIQUOR ACRIFLAVINÆ**(Liq. Acriflavin.)****Solution of Acriflavine**

	<i>Metric</i>	<i>Imperial</i>
Acriflavine	1 g.	8¾ gr.
Physiological Solution of Sodium Chloride	to 1000 ml.	to 20 fl. oz.

Dissolve.

LIQUOR ÆTHYLIS NITRITIS**(Liq. Æthyl. Nitrit.)****Solution of Ethyl Nitrite**

Solution of ethyl nitrite is a solution of ethyl nitrite in a mixture of ninety-five parts by volume of dehydrated alcohol with five parts by volume of glycerin. The ethyl nitrite may be obtained by the interaction of alcohol, sodium nitrite and dilute sulphuric acid, at a low temperature. It should be **stored** in small, well-closed bottles, protected from light and in a cool place.

Standard.—Solution of ethyl nitrite, determined by the method of the British Pharmacopœia for Spiritus Ætheris Nitrosi, contains not less than 2·0 per cent. and not more than 2·5 per cent. w/v of $C_2H_5O_2N$, corresponding to not less than 2·5 per cent. and not more than 3·0 per cent. w/w of ethyl nitrite. Specific gravity, 0·823 to 0·826.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

LIQUOR ALKALINUS

(Liq. Alk.)

Alkaline Solution

Synonyms—Collunarium Alkalinum; Alkaline Nasal Wash.

				<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	15 g.	131 $\frac{1}{4}$ gr.
Borax	15 g.	131 $\frac{1}{4}$ gr.
Phenol	5 g.	43 $\frac{3}{4}$ gr.
Sucrose	25 g.	$\frac{1}{2}$ oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve.

LIQUOR ALUMINII ACETATIS

(Liq. Alumin. Acet.)

Solution of Aluminium Acetate

Synonyms—Liquor Aluminii Aceticus; Burow's Solution.

				<i>Metric</i>	<i>Imperial</i>
Aluminium Sulphate	225 g.	4 $\frac{1}{2}$ oz.
Acetic Acid	250 ml.	5 fl. oz.
Calcium Carbonate	100 g.	2 oz.
Distilled Water	750 ml.	15 fl. oz.

Dissolve the aluminium sulphate in 600 millilitres (12 fluid ounces) of the distilled water, add the acetic acid, and then the calcium carbonate mixed with the remainder of the water. Allow to stand for twenty-four hours in a cool place, stirring occasionally, and filter.

LIQUOR AMMONIÆ ANISATUS

(Liq. Ammon. Anisat.)

Anisated Solution of Ammonia

Synonyms—Liquor Ammonii Anisatus, Spiritus Ammoniaë Anisatus.

				<i>Metric</i>	<i>Imperial</i>
Oil of Anise	33·3 ml.	320 m.
Dilute Solution of Ammonia	166·7 ml.	3 fl. oz. 160 m.
Alcohol (90 per cent.) to 1000·0 ml.		to 20 fl. oz.

Dissolve the oil of anise in 800 millilitres (16 fluid ounces) of the alcohol, add the dilute solution of ammonia and sufficient of the alcohol to produce the required volume.

Dose.— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

LIQUOR AMMONIÆ AROMATICUS

(*Liq. Ammon. Aromat.*)

Aromatic Solution of Ammonia

	<i>Metric</i>	<i>Imperial</i>
Ammonium Carbonate ..	25.0 g.	$\frac{1}{2}$ oz.
Strong Solution of Ammonia	50.0 ml.	1 fl. oz.
Terpeneless Oil of Lemon	0.2 ml.	2 m.
Terpeneless Oil of Nutmeg	0.4 ml.	4 m.
Alcohol (90 per cent.) ..	37.5 ml.	360 m.
Distilled Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the ammonium carbonate in 800 millilitres (16 fluid ounces) of distilled water; add the terpeneless oils of lemon and nutmeg dissolved in the alcohol, the strong solution of ammonia and sufficient distilled water to produce the required volume. Add 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, shake well and filter.

Standard.—Aromatic solution of ammonia, determined by the method of the British Pharmacopœia for Spiritus Ammoniaë Aromaticus, contains not less than 2.1 per cent. and not more than 2.4 per cent. w/v of NH_3 , and not less than 1.265 per cent. and not more than 1.485 per cent. w/v of CO_2 .

Dose.— 1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

LIQUOR AMMONII CITRATIS DILUTUS

(*Liq. Ammon. Cit. Dil.*)

Dilute Solution of Ammonium Citrate

Synonyms—Liquor Ammonii Citratis; Solution of Ammonium Citrate.

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ammonium Citrate	250 ml.	5 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Mix.

It should be **stored** in a bottle of lead-free glass.

Dose.— 8 to 24 millilitres (2 to 6 fluid drachms).

LIQUOR AMMONII CITRATIS FORTIS

(Liq. Ammon. Cit. Fort.)

Strong Solution of Ammonium Citrate

	<i>Metric</i>	<i>Imperial</i>
Citric Acid, in powder ..	500 g.	10 oz.
Strong Solution of Ammonia ..	a sufficient quantity	
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add sufficient strong solution of ammonia gradually to the citric acid to produce a solution of which one drop of the resulting solution diluted with ten drops of distilled water gives a full blue colour with one drop of solution of bromo-thymol blue and a full yellow colour with one drop of solution of thymol blue, and add sufficient distilled water to produce the required volume.

It should be **stored** in a bottle of lead-free glass.

Standard.—Strong solution of ammonium citrate, determined by the method of the British Pharmacopœia for Liquor Ammonii Acetatis Fortis, contains not less than 55 per cent. and not more than 60 per cent. w/v of $C_6H_5O_7(NH_4)_3$; each millilitre of N/1 sodium hydroxide is equivalent to 0.08105 gramme of $C_6H_5O_7(NH_4)_3$. Specific gravity, about 1.209. The reaction of 1 millilitre, diluted with 10 millilitres of water, is not less than pH 7.0 and not more than pH 8.0.

Dose.—2 to 6 millilitres ($\frac{1}{2}$ to $1\frac{1}{2}$ fluid drachms).

LIQUOR ARSENI ACIDUS

(Liq. Arsen. Acid.)

Acid Solution of Arsenic*Synonym*—Liquor Arsenici Hydrochloricus.

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide, in powder ..	10 g.	87½ gr.
Hydrochloric Acid	12 ml.	115 m.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the hydrochloric acid with 500 millilitres (10 fluid ounces) of distilled water and heat to boiling; add the arsenic trioxide and heat gently until dissolved; cool, and add sufficient distilled water to produce the required volume.

Standard.—Acid solution of arsenic, determined by the method of the British Pharmacopœia for Liquor Arsenicalis, employing a slight excess of sodium bicarbonate, contains not less than 0.95 per cent. and not more than 1.05 per cent. w/v of As_2O_3 .

Dose.—0.12 to 0.5 millilitre (2 to 8 minims).

LIQUOR ARSENI ALKALINUS

(Liq. Arsen. Alk.)

Alkaline Solution of Arsenic

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide, in powder	10 g.	87½ gr.
Potassium Carbonate	10 g.	87½ gr.
Compound Tincture of Lavender	30 ml.	288 m.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve the arsenic trioxide and the potassium carbonate in 100 millilitres (2 fluid ounces) of distilled water with the aid of heat; cool, add the compound tincture of lavender and sufficient distilled water to produce the required volume.

Standard.—Alkaline solution of arsenic, determined after neutralisation with hydrochloric acid by the method of the British Pharmacopœia for Liquor Arsenicalis, contains not less than 0·95 per cent. and not more than 1·05 per cent. w/v of As_2O_3 .

Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

LIQUOR ATROPINÆ SULPHATIS

(Liq. Atrop. Sulph.)

Solution of Atropine Sulphate

	<i>Metric</i>	<i>Imperial</i>
Atropine Sulphate	10 g.	87½ gr.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve.

It should be freshly prepared.

Dose.—0·03 to 0·06 millilitre (½ to 1 minim).

LIQUOR AURI ET ARSENI BROMINATUS

(Liq. Aur. et Arsen. Brominat.)

Brominated Solution of Gold and Arsenic

Synonyms—Liquor Auri et Arsenii Bromidi; Liquor Auri Bromidi Arsenatus.

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	4·6 g.	40 gr.
Potassium Carbonate	4·6 g.	40 gr.
Bromine	11·4 g.	100 gr.
Gold, in leaf, pure	1·5 g.	13 gr.
Distilled Water to 1000·0 ml.		to 20 fl. oz.

Add the arsenic trioxide and potassium carbonate to 200 millilitres (4 fluid ounces) of the distilled water in a flask, and boil until solution is complete; place the gold leaf in a wide-mouthed bottle, add 600 millilitres (12 fluid ounces) of distilled water, run in the bromine and shake until it is dissolved; add the solution of arsenic trioxide and shake for a

few seconds. Transfer the mixture to a flask and boil until bromine vapours are no longer given off; allow to cool, add sufficient distilled water to produce the required volume, and filter.

Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

LIQUOR AZORUBRI

(Liq. Azorub.)

Solution of Bordeaux B

Synonym—Liquor Ruber.

				<i>Metric</i>	<i>Imperial</i>
Bordeaux B	10 g.	87½ gr.
Glycerin	250 ml.	5 fl. oz.
Chloroform Water	to 1000 ml.		to 20 fl. oz.

Dissolve the bordeaux B in about 700 millilitres (14 fluid ounces) of the chloroform water, warming on a water-bath if necessary; cool, add the glycerin and sufficient chloroform water to produce the required volume; filter if necessary.

LIQUOR BISMUTHI ACIDUS

(Liq. Bism. Acid.)

Acid Solution of Bismuth

				<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate	125.0 g.	2½ oz.
Tartaric Acid	a sufficient quantity	
Sodium Hydroxide	a sufficient quantity	
Chloroform	2.5 ml.	24 m.
Distilled Water	to 1000.0 ml.		to 20 fl. oz.

Triturate the bismuth subnitrate with 98.2 grammes (1 ounce 420 grains) of tartaric acid and 150 millilitres (3 fluid ounces) of distilled water, continuing to stir until a thick paste is formed, and allow to stand until a small portion of the mixture is completely soluble in dilute solution of ammonia. Add gradually about 200 millilitres (4 fluid ounces) of a 0.375 per cent. w/v aqueous solution of tartaric acid, triturating constantly to produce a thin cream; add 800 millilitres of the same tartaric acid solution and allow to stand. Decant the clear liquid, repeat the washing by decantation, using four successive quantities each of about 1000 millilitres (20 fluid ounces) of the tartaric acid solution, collect and drain the precipitate. Mix the moist product with 30.82 grammes (269½ grains) of tartaric acid, allow to stand for one hour, dilute with 100 millilitres (2 fluid ounces) of distilled water, and add 175 millilitres (3½ fluid ounces) of a 20 per cent. w/v aqueous solution of sodium hydroxide. Carefully add, if necessary, a further quantity of sodium hydroxide in dilute aqueous solution until the liquid is neutral to bromocresol green or slightly acid to methyl red (pH 4.6), add the chloroform and sufficient distilled water to produce the required volume; shake until the chloroform is dissolved.

Standard.—Acid solution of bismuth contains the equivalent of not less than 9 per cent. and not more than 11 per cent. w/v of Bi_2O_3 .

Assay.—Evaporate 5 millilitres to dryness, and ignite the residue at a dull red heat. Extract the residue with boiling water, dry the insoluble matter, add a few drops of nitric acid, ignite, and weigh the residue of Bi_2O_3 .

Dose.—1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm).

LIQUOR BISMUTHI CONCENTRATUS

(Liq. Bism. Conc.)

Concentrated Solution of Bismuth

Concentrated solution of bismuth may be prepared by dissolving bismuth citrate in dilute solution of ammonia and diluting the solution with distilled water, or by the following process:—

	<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate ..	140 g.	2 oz. 350 gr.
Citric Acid, in powder ..	104 g.	2 oz. 35 gr.
Dilute Solution of Ammonia ..	a sufficient quantity	
Distilled Water to 1000 ml.	to 20 fl. oz.

Mix the citric acid with the bismuth subnitrate and 4 millilitres (40 minims) of distilled water. Heat the mixture on a water-bath until a small portion is completely soluble in dilute solution of ammonia. Transfer the mixture to a filter and wash with distilled water until the washings give no reaction for nitrate. Add to the washed residue just sufficient dilute solution of ammonia to dissolve it, and then add sufficient distilled water to produce the required volume.

Standard.—Concentrated solution of bismuth, determined by the method described under *Liquor Bismuthi et Ammonii Citratis*, contains the equivalent of not less than 10 per cent. and not more than 12 per cent. w/v of Bi_2O_3 .

Dose.—1 to 2 millilitres ($\frac{1}{4}$ to $\frac{1}{2}$ fluid drachm).

LIQUOR BISMUTHI ET AMMONII CITRATIS

(Liq. Bism. et Ammon. Cit.)

Solution of Bismuth and Ammonium Citrate

Synonyms—*Liquor Bismuthi*; *Liquor Bismuthi Citratis*.

Solution of bismuth and ammonium citrate may be prepared by dissolving bismuth citrate in dilute solution of ammonia and diluting the solution with distilled water, or by the following process:—

	<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate	70 g.	1 oz. 175 gr.
Citric Acid, in powder	52 g.	1 oz. 17½ gr.
Dilute Solution of Ammonia ..	a sufficient quantity	
Distilled Water to 1000 ml.	to 20 fl. oz.

Mix the citric acid with the bismuth subnitrate and 2 millilitres (20 minims) of distilled water. Heat the mixture on a water-bath until a small portion is completely soluble in dilute solution of ammonia. Transfer the mixture to a filter and wash with distilled water until the washings give no reaction for nitrate. Add to the washed residue just sufficient dilute solution of ammonia to dissolve it, and then add sufficient distilled water to produce the required volume.

Standard.—Solution of bismuth and ammonium citrate contains the equivalent of not less than 5.0 per cent. and not more than 6.0 per cent. w/v of Bi_2O_3 .

Assay.—Evaporate 10 millilitres to dryness, ignite the residue at a dull red heat, re-ignite with a few drops of nitric acid, and weigh the residue of Bi_2O_3 .

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LIQUOR BORACIS COMPOSITUS

(Liq. Borac. Co.)

Compound Solution of Borax

Synonyms—Collunarium Acidi Carbolici Compositum; Dobell's Solution.

	<i>Metric</i>	<i>Imperial</i>
Borax	15 g.	131 $\frac{1}{4}$ gr.
Sodium Bicarbonate	15 g.	131 $\frac{1}{4}$ gr.
Phenol	3 g.	26 $\frac{1}{4}$ gr.
Glycerin	35 ml.	336 m.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the borax and sodium bicarbonate in about 500 millilitres (10 fluid ounces) of the water; add the glycerin, phenol, and sufficient distilled water to produce the required volume, and filter.

LIQUOR BROMIDI COMPOSITUS

(Liq. Brom. Co.)

Compound Bromide Solution

Synonym—Liquor Bromochloral Compositus.

	<i>Metric</i>	<i>Imperial</i>
Chloral Hydrate	275.0 g.	5 $\frac{1}{2}$ oz.
Potassium Bromide	275.0 g.	5 $\frac{1}{2}$ oz.
Extract of Cannabis	2.3 g.	20 gr.
Liquid Extract of Hyoscyamus	13.8 ml.	132 $\frac{1}{2}$ m.
Tincture of Orange	125.0 ml.	2 $\frac{1}{2}$ fl. oz.
Glycerin	187.5 ml.	3 $\frac{3}{4}$ fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate the chloral hydrate with the extract of cannabis, dissolve the mixture in the tincture of orange, and add the liquid extract of hyoscyamus; dissolve the potassium bromide in the glycerin diluted with sufficient distilled water to produce a volume of 750 millilitres (15 fluid ounces), and add it to the first solution; add sufficient distilled water to produce the required volume, set aside for twenty-four hours, and filter.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

LIQUOR CALCII HYDROXIDI SACCHARATUS

(*Liq. Calc. Hydrox. Sacch.*)

Saccharated Solution of Calcium Hydroxide

Synonyms.—Liquor Calcis Saccharatus; Saccharated Solution of Lime.

			<i>Metric</i>	<i>Imperial</i>
Calcium Hydroxide	50 g.	1 oz.
Sucrose	100 g.	2 oz.
Distilled Water	1000 ml.	20 fl. oz.

Mix the calcium hydroxide with a solution of the sucrose in the distilled water. Set aside in a stoppered, green glass bottle for a few hours, shaking occasionally; separate the clear solution by means of a siphon, avoiding unnecessary exposure to air.

Standard.—Saccharated solution of calcium hydroxide contains the equivalent of not less than 2·4 per cent. w/v of Ca(OH)_2 . Specific gravity, about 1·055. Lead limit, 2 parts per million.

Assay.—Titrate 20 millilitres with N/1 hydrochloric acid, using methyl orange as indicator; each millilitre of N/1 hydrochloric acid is equivalent to 0·03705 gramme of Ca(OH)_2 .

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

LIQUOR CALCII LACTATIS

(*Liq. Calc. Lact.*)

Solution of Calcium Lactate

			<i>Metric</i>	<i>Imperial</i>
Calcium Carbonate	16 g.	140 gr.
Lactic Acid	35 ml.	336 m.
Chloroform Water	to 1000 ml.	to 20 fl. oz.

Mix the lactic acid with 900 millilitres (18 fluid ounces) of the chloroform water, gradually add the calcium carbonate, stirring to promote effervescence, and finally add sufficient chloroform water to produce the required volume.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

LIQUOR CALCIS CHLORINATÆ

(Liq. Calc. Chlorinat.)

Solution of Chlorinated Lime

			<i>Metric</i>	<i>Imperial</i>
Chlorinated Lime	100 g.	2 oz.
Distilled Water	1000 ml.	20 fl. oz.

Mix, transfer the mixture to a stoppered bottle, set aside for three hours, shaking occasionally, and filter through calico.

It should be **stored** in a stoppered bottle in a cool dark place and protected from light.

Standard.—Solution of chlorinated lime, determined by the method for Liquor Sodæ Chlorinatæ, yields not less than 2 per cent. w/v of available chlorine.

LIQUOR CALCIS CHLORINATÆ CUM ACIDO BORICO

(Liq. Calc. Chlorinat. c. Acid. Boric.)

Solution of Chlorinated Lime with Boric Acid*Synonym*—Eusol.

			<i>Metric</i>	<i>Imperial</i>
Chlorinated Lime	12.5 g.	$\frac{1}{4}$ oz.
Boric Acid, in powder	12.5 g.	$\frac{1}{4}$ oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Reduce the chlorinated lime to fine powder, triturate it with the water to form a paste, and add the remainder of the water. Add the boric acid, shake well, allow to stand several hours, and filter.

It should be **stored** in well-closed containers in a cool place and protected from light, and should not be used when more than three weeks old.

LIQUOR CALCIS SULPHURATÆ

(Liq. Calc. Sulphurat.)

Solution of Sulphurated Lime*Synonyms*—Lotio Calcis Sulphuratæ; Vlemminckx's Solution.

			<i>Metric</i>	<i>Imperial</i>
Calcium Oxide	25 g.	$\frac{1}{2}$ oz.
Sublimed Sulphur	50 g.	1 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Slake the calcium oxide with an equal quantity of distilled water, add the sulphur and 500 millilitres (10 fluid ounces) of the water, and boil in a flask until the sulphur is dissolved. Allow the liquid to cool,

filter, and pass sufficient distilled water through the filter to produce the required volume.

It should be **stored** in completely-filled, well-closed containers.

Standard.—Solution of sulphurated lime contains not less than 4 per cent. and not more than 5 per cent. w/v of total sulphur.

Assay.—Boil 2 millilitres with 10 millilitres of water and 5 millilitres of sodium hydroxide solution, and add slowly, rotating the flask, bromine solution As T until bromine is in excess. Acidify with hydrochloric acid, boil off the bromine, and add a slight excess of barium chloride. Heat for thirty minutes on a water-bath, filter, wash the precipitate, dry and weigh; each gramme of BaSO_4 is equivalent to 0.1373 gramme of sulphur.

LIQUOR CANTHARIDINI

(Liq. Cantharidin.)

Solution of Cantharidin

Synonyms.—Tinctura Cantharidini; Tincture of Cantharidin.

	<i>Metric</i>	<i>Imperial</i>
Cantharidin	0.1 g.	$\frac{7}{8}$ gr.
Chloroform	10.0 ml.	96 m.
Alcohol (90 per cent.)	to 1000.0 ml.	to 20 fl. oz.

Dissolve the cantharidin in the chloroform, and add sufficient alcohol (90 per cent.) to produce the required volume.

Dose.—0.12 to 0.3 millilitre (2 to 5 minims).

LIQUOR CARMINI

(Liq. Carmin.)

Solution of Carmine

	<i>Metric</i>	<i>Imperial</i>
Carmine	60 g.	1 oz. 87½ gr.
Dilute Solution of Ammonia	150 ml.	3 fl. oz.
Potassium Citrate	100 ml.	2 oz.
Glycerin	350 ml.	7 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Triturate the carmine with the dilute solution of ammonia, add the glycerin, and heat on a water-bath for five minutes or until the carmine is dissolved; cool, dissolve the potassium citrate in the mixture, and add sufficient distilled water to produce the required volume. Filter if necessary.

LIQUOR CAULOPHYLLI ET PULSATILLÆ

(Liq. Cauloph. et Pulsat.)

Solution of Caulophyllum and Pulsatilla

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Caulophyllum	250 ml.	5 fl. oz.
Liquid Extract of Pulsatilla ..	50 ml.	1 fl. oz.
Glycerin	150 ml.	3 fl. oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).**LIQUOR CAULOPHYLLI ET PULSATILLÆ COMPOSITUS**

(Liq. Cauloph. et Pulsat. Co.)

Compound Solution of Caulophyllum and Pulsatilla

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Caulophyllum	150 ml.	3 fl. oz.
Liquid Extract of Pulsatilla ..	50 ml.	1 fl. oz.
Liquid Extract of Alctris ..	100 ml.	2 fl. oz.
Liquid Extract of Black Haw ..	200 ml.	4 fl. oz.
Glycerin	200 ml.	4 fl. oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix, allow to stand for twenty-four hours, and filter.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).**LIQUOR CHLORI**

(Liq. Chlori)

Solution of Chlorine*Synonym*—Aqua Chlori.

Solution of chlorine may be prepared by passing washed chlorine gas, obtained by the evaporation of liquid chlorine or by dropping concentrated hydrochloric acid on solid potassium permanganate, into distilled water until the solution contains somewhat more than 0.5 per cent. w/v of chlorine. Solution of chlorine may also be obtained by the following process :—Heat gently 32.5 grammes (284 grains) of granular manganese dioxide with 200 millilitres (4 fluid ounces) of hydrochloric acid and 65 millilitres (1 fluid ounce 144 minims) of distilled water and pass the resulting gas through a wash-bottle containing 50 millilitres (1 fluid ounce) of distilled water into a receiver containing 1000 millilitres (20 fluid ounces) of distilled water; when gas ceases to be evolved, shake the receiver until the chlorine is absorbed.

It should be **stored** in well-closed containers, protected from light.

LIQUOR CHROMII TRIOXIDI

(Liq. Chrom. Triox.)

Solution of Chromium Trioxide*Synonym*—Liquor Acidi Chromici.

			<i>Metric</i>	<i>Imperial</i>
Chromium Trioxide	250 g.	5 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.
Dissolve.				

LIQUOR COCCI

(Liq. Cocc.)

Solution of Cochineal*Synonym*—Liquid Cochineal.

			<i>Metric</i>	<i>Imperial</i>
Cochineal	100 g.	2 oz.
Potassium Carbonate	10 g.	87½ gr.
Potassium Citrate	100 g.	2 oz.
Alcohol (90 per cent.)	200 ml.	4 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the potassium carbonate in 600 millilitres (12 fluid ounces) of the distilled water and digest the cochineal in the solution on a water-bath for about two hours, replacing the water lost by evaporation; then strain through muslin, cool, add the alcohol and potassium citrate, and sufficient distilled water to produce the required volume.

LIQUOR COPAIBÆ

(Liq. Copaib.)

Solution of Copaiba*Synonym*—Soluble Copaiba.

			<i>Metric</i>	<i>Imperial</i>
Copaiba	500 ml.	10 fl. oz.
Solution of Potassium Hydroxide	800 ml.	16 fl. oz.
Distilled Water	∴	..	to 1000 ml.	to 20 fl. oz.

Add the copaiba to 750 millilitres (15 fluid ounces) of the solution of potassium hydroxide, boil for one hour, add 250 millilitres (5 fluid ounces) of the water, mix thoroughly, and allow to cool; separate the clear liquid from the oil and sediment, evaporate to 950 millilitres (19 fluid ounces), add the remainder of the solution of potassium hydroxide, and filter through purified talc or kaolin.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

LIQUOR COPAIBÆ, BUCHU ET CUBEBÆ

(Liq. Copaib. Buchu et Cubeb.)

Solution of Copaiba, Buchu and Cubeb

	<i>Metric</i>	<i>Imperial</i>
Solution of Copaiba	800 ml.	16 fl. oz.
Liquid Extract of Buchu	100 ml.	2 fl. oz.
Liquid Extract of Cubeb	100 ml.	2 fl. oz.

Mix and filter through purified talc or kaolin.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).**LIQUOR COPAIBÆ, BUCHU ET CUBEBÆ CUM OLEO SANTALI**

(Liq. Copaib. Buchu et Cubeb. c. Ol. Santal.)

Solution of Copaiba, Buchu and Cubeb with Sandal Wood Oil

	<i>Metric</i>	<i>Imperial</i>
Solution of Copaiba, Buchu and Cubeb	800 ml.	16 fl. oz.
Oil of Sandal Wood	100 ml.	2 fl. oz.
Oil of Cassia	5 ml.	48 m.
Alcohol (90 per cent.)	95 ml.	1 fl. oz. 432 m.

Mix the oil of sandal wood and the oil of cassia with the alcohol, add the solution of copaiba, buchu and cubeb, and filter through purified talc or kaolin.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).**LIQUOR COPAIBÆ ET OLEI SANTALI**

(Liq. Copaib. et Ol. Santal.)

Solution of Copaiba and Sandal Wood Oil

	<i>Metric</i>	<i>Imperial</i>
Solution of Copaiba	800 ml.	16 fl. oz.
Oil of Sandal Wood	100 ml.	2 fl. oz.
Oil of Cassia	5 ml.	48 m.
Alcohol (90 per cent.)	95 ml.	1 fl. oz. 432 m.

Mix the oils of sandal wood and cassia with the alcohol, add the solution of copaiba, and filter through purified talc or kaolin.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

LIQUOR DEXTROSI ET SODII CHLORIDI

(Liq. Dextros. et Sod. Chlorid.)

Dextrose and Sodium Chloride Solution*Synonym*—Glucose-saline Solution.

			<i>Metric</i>	<i>Imperial</i>
Dextrose	50 g.	1 oz.
Sodium Chloride	9 g.	78½ gr.
Sterilised Water to 1000 ml.		to 20 fl. oz.

Dissolve, and sterilise by heating in an autoclave, by tyndallisation or by filtration.

When required for intravenous injection, it should be prepared with sterilised water for intravenous injections.

LIQUOR EUONYMINI ET IRIDINI

(Liq. Euonym. et Iridin.)

Solution of Euonymin and Iridin

			<i>Metric</i>	<i>Imperial</i>
Extract of Euonymus	36.6 g.	320 gr.
Extract of Iris	18.3 g.	160 gr.
Potassium Carbonate	13.7 g.	120 gr.
Distilled Water	250.0 ml.	5 fl. oz.
Alcohol (45 per cent.) to 1000.0 ml.		to 20 fl. oz.

Triturate the extracts with 500 millilitres (10 fluid ounces) of the alcohol in a mortar, and filter; to the filtrate add the potassium carbonate previously dissolved in the distilled water, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

LIQUOR EUONYMINI ET PEPSINI

(Liq. Euonym. et Pepsin.)

Solution of Euonymin and Pepsin

			<i>Metric</i>	<i>Imperial</i>
Extract of Euonymus	18.3 g.	160 gr.
Pepsin	36.6 g.	320 gr.
Dilute Hydrochloric Acid	36.5 ml.	350 m.
Alcohol (45 per cent.)	300.0 ml.	6 fl. oz.
Chloroform Water to 1000.0 ml.		to 20 fl. oz.

Dissolve the pepsin in the dilute hydrochloric acid mixed with 500 millilitres (10 fluid ounces) of the chloroform water; triturate the extract of euonymus with the alcohol, filter into the pepsin solution and pass sufficient of the chloroform water through the filter to produce the required volume.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

LIQUOR FERRI DIALYSATI

(Liq. Ferr. Dialysat.)

Solution of Dialysed Iron

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ferric Chloride	700 ml.	7 fl. oz.
Dilute Solution of Ammonia ..	a sufficient quantity	
Distilled Water	a sufficient quantity	

Mix 600 millilitres (6 fluid ounces) of the strong solution of ferric chloride with 4000 millilitres (40 fluid ounces) of distilled water and stir into the mixture sufficient dilute solution of ammonia to impart, after thorough agitation, a distinct ammoniacal odour. Filter through calico, wash the precipitated ferric hydroxide with distilled water and press it to remove superfluous moisture. Add the precipitate to the remainder of the strong solution of ferric chloride, stir thoroughly, warm gently and, when complete or nearly complete solution is obtained, filter if necessary; place the liquid in a covered dialyser and subject it to a stream of water in the usual manner until the solution in the dialyser is almost tasteless. Adjust the resulting solution to measure 2800 millilitres (28 fluid ounces).

Standard.—Solution of dialysed iron contains not less than 3 per cent. and not more than 4 per cent. w/v of Fe. Specific gravity, about 1.049.

Assay.—Dilute about 5 grammes, accurately weighed, with 20 millilitres of water, add 3 millilitres of hydrochloric acid, boil for fifteen seconds, cool, dissolve 3 grammes of potassium iodide in the cold solution and, without further dilution, titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0.005584 gramme of Fe. From the specific gravity of the solution calculate the percentage w/v.

Dose.—0.6 to 2 millilitres (10 to 30 minims).

LIQUOR FERRI HYPOPHOSPHITIS

(Liq. Ferr. Hypophosph.)

Solution of Iron Hypophosphite

Synonym—Liquor Ferri Hypophosphitis Fortis; Strong Solution of Iron Hypophosphite.

	<i>Metric</i>	<i>Imperial</i>
Solution of Ferric Sulphate ..	142 ml.	2 fl. oz. 403 m.
Dilute Solution of Ammonia ..	230 ml.	4 fl. oz. 288 m.
Citric Acid	76 g.	1 oz. 227½ gr.
Sodium Hypophosphite	96 g.	1 oz. 402½ gr.
Sodium Citrate	66 g.	1 oz. 140 gr.
Distilled Water	a sufficient quantity	
Double Chloroform Water ..	to 1000 ml.	to 20 fl. oz.

Mix the dilute solution of ammonia with an equal volume of distilled water, gradually add the solution of ferric sulphate previously diluted with an equal volume of water, wash the precipitated ferric hydroxide by decantation with distilled water until free from sulphates, collect on a calico filter, drain, and transfer the moist precipitate to a porcelain dish; add the citric acid and 200 millilitres (4 fluid ounces) of distilled water, and heat on a water-bath, with occasional stirring, until a clear solution results; then add the sodium hypophosphite, continue the heating on the water-bath with stirring for about one minute or until a clear greenish solution is obtained; add the sodium citrate, filter, and pass sufficient double chloroform water through the filter to produce the required volume.

Standard.—Solution of iron hypophosphite contains not less than 8·5 per cent. and not more than 10·5 per cent. w/v of $\text{Fe}(\text{H}_2\text{PO}_2)_3$.

Assay.—Dilute 5 millilitres with water to 100 millilitres, transfer 10 millilitres to a stoppered bottle and proceed as described under Ferri Hypophosphis.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

LIQUOR FERRI IODIDI

(Liq. Ferr. Iod.)

Solution of Ferrous Iodide

	<i>Metric</i>	<i>Imperial</i>
Iron	150 g.	3 oz.
Iodine	464 g.	9 oz. 122½ gr.
Dilute Hypophosphorous Acid..	80 ml.	1 fl. oz. 288 m.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Place the iron and the iodine in a flask having a capacity of at least 4000 millilitres (80 fluid ounces) with 800 millilitres (16 fluid ounces) of the distilled water and allow the reaction to proceed until the liquid loses its brown colour. Heat the solution to boiling-point, cool, filter through starch-free filter paper into the dilute hypophosphorous acid, and pass sufficient previously boiled and cooled distilled water through the filter to produce the required volume.

It should be **stored** in small, completely-filled, well-closed bottles and exposed to the light.

Standard.—Solution of ferrous iodide contains not less than 53·1 per cent. and not more than 54·2 per cent. w/v of FeI_2 . Specific gravity, about 1·45.

Assay.—Dilute about 0·7 gramme, accurately weighed, with 50 millilitres of water and proceed by the method of the British Pharmacopœia for Syrupus Ferri Iodidi. From the specific gravity, calculate the percentage w/v.

Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

Solution of ferrous iodide when diluted with seven times its volume of syrup forms Syrupus Ferri Iodidi.

LIQUOR FERRI OXYCHLORIDI**(Liq. Ferr. Oxychlor.)****Solution of Ferric Oxychloride**

Synonyms—Soluble Peroxide of Iron; Solution of Chloroxide of Iron;
Solution of Basic Ferric Chloride.

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ferric Chloride	225·0 g.	4½ oz.
Dilute Solution of Ammonia	350·0 g.	7 oz.
Hydrochloric Acid	23·5 g.	206 gr.
Distilled Water to 1000·0 g.		to 20 oz.

Mix the dilute solution of ammonia with 3200 millilitres (64 fluid ounces) of distilled water, and add slowly, with constant stirring, the strong solution of ferric chloride previously diluted with 1600 millilitres (32 fluid ounces) of distilled water. Filter through calico, wash the precipitated ferric hydroxide with distilled water and press it to remove superfluous moisture. Mix the hydrochloric acid with the precipitate, stir the mixture at intervals during three days, then heat if necessary to about 40° to complete the solution, and add sufficient distilled water to produce the required weight.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

LIQUOR FERRI PEPTONATIS**(Liq. Ferr. Pepton.)****Solution of Iron Peptonate**

Synonym—Solution of Peptonised Iron.

	<i>Metric</i>	<i>Imperial</i>
Peptone	40 g.	350 gr.
Solution of Ferric Oxychloride	200 ml.	4 fl. oz.
Solution of Potassium Hydroxide	a sufficient quantity	
Alcohol (90 per cent.)	125 ml.	2½ fl. oz.
Aromatic Elixir	400 ml.	8 fl. oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve the peptone in 2000 millilitres (40 fluid ounces) of distilled water, add the solution of ferric oxychloride, previously diluted with 2000 millilitres (40 fluid ounces) of distilled water, and neutralise to litmus paper by adding a sufficient quantity of solution of potassium hydroxide. Rapidly wash the flocculent precipitate with distilled water by decantation until the washings give not more than a faint opalescence with solution of silver nitrate, drain the precipitate, transfer to a porcelain dish, add 80 millilitres (1 fluid ounce 288 minims) of solution of

potassium hydroxide, stir, and while stirring add distilled water, not exceeding 75 millilitres ($1\frac{1}{2}$ fluid ounces), to dissolve the precipitate. Finally add the alcohol and aromatic elixir, previously mixed, and sufficient distilled water to produce the required volume.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

LIQUOR FERRI PEPTONATIS CUM MANGANO

(*Liq. Ferr. Pepton. c. Mang.*)

Solution of Iron Peptonate with Manganese

Synonym—Solution of Peptonised Iron with Manganese.

		<i>Metric</i>	<i>Imperial</i>
Manganese Chloride	3·4 g.	30 gr.
Solution of Iron Peptonate	to 1000·0 ml.		to 20 fl. oz.

Dissolve.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

LIQUOR FERRI PERCHLORIDI FORTIS

(*Liq. Ferr. Perchlor. Fort.*)

Strong Solution of Ferric Chloride

Strong solution of ferric chloride may be prepared by the following process:—

		<i>Metric</i>	<i>Imperial</i>
Iron	210 g.	7 oz.
Hydrochloric Acid	1230 ml.	41 fl. oz.
Nitric Acid	90 ml.	3 fl. oz.
Distilled Water	a sufficient quantity	

Place the iron in a flask, add a mixture of 750 millilitres (25 fluid ounces) of hydrochloric acid and 420 millilitres (14 fluid ounces) of distilled water, and heat at a moderate temperature until effervescence ceases; then boil, filter from undissolved iron, rinse the flask and contents with a little distilled water and pour the rinsings over the filter. Add to the filtrate 420 millilitres (14 fluid ounces) of hydrochloric acid, mix, and pour the solution in a slow continuous stream into the nitric acid, chemical action being promoted, if necessary, by gently warming. Evaporate the product until a precipitate begins to form, add 60 millilitres (2 fluid ounces) of hydrochloric acid, and sufficient distilled water to produce 1050 millilitres (35 fluid ounces) or to make the resulting solution correspond to the following tests.

Standard.—Strong solution of ferric chloride contains not less than 58·5 per cent. and not more than 61·5 per cent. w/v of FeCl_3 . When diluted with three times its volume of water, it yields a solution which complies with the tests for purity of the British Pharmacopœia for Liquor Ferri Perchloridi. Specific gravity, about 1·43. Lead limit, 50 parts per million.

Assay.—Dilute about 0·7 gramme, accurately weighed, with 50 millilitres of water and proceed by the method of the British Pharmacopœia for Liquor Ferri Perchloridi. From the specific gravity, calculate the percentage w/v.

LIQUOR FERRI PERSULPHATIS

(Liq. Ferr. Persulph.)

Solution of Ferric Sulphate

		<i>Metric</i>	<i>Imperial</i>
Ferrous Sulphate..	800 g.	16 oz.
Sulphuric Acid	75 ml.	1½ fl. oz.
Nitric Acid..	75 ml.	1½ fl. oz.
Distilled Water	to 1100 ml.	to 22 fl. oz.

Add the sulphuric acid to 1000 millilitres (20 fluid ounces) of the distilled water and dissolve the ferrous sulphate in the mixture with the aid of heat. Mix the nitric acid with 200 millilitres (4 fluid ounces) of the distilled water and add to this diluted acid, warmed, the solution of ferrous sulphate; concentrate by boiling until, on the sudden disengagement of ruddy vapours, the liquid ceases to be black and acquires a red colour. If any ferrous salt remains in solution, add a few drops of nitric acid and boil again. When the solution is cold add, if necessary, sufficient distilled water to produce the required volume.

Standard.—Solution of ferric sulphate contains not less than 14 per cent. and not more than 15 per cent. w/v of Fe. Specific gravity, about 1·44. Arsenic limit, 5 parts per million. 1 millilitre diluted with water yields no blue colouration on the addition of potassium ferricyanide solution (absence of ferrous salts).

Assay.—Dilute about 1·5 gramme-, accurately weighed, with 25 millilitres of water, add 7 millilitres of hydrochloric acid, dissolve 3·5 grammes of potassium iodide in the solution and, without further dilution, titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0·005584 gramme of Fe. From the specific gravity, calculate the percentage w/v.

LIQUOR FERRI PHOSPHATIS**(Liq. Ferr. Phosph.)****Solution of Ferrous Phosphate**

		<i>Metric</i>	<i>Imperial</i>
Iron	68.8 g.	1 oz. 164½ gr.
Phosphoric Acid	320.0 ml.	6 fl. oz. 192 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Place the iron and the phosphoric acid, previously diluted with half its volume of water, in a flask, heat gently until the iron is dissolved, add sufficient distilled water to produce the required volume, and filter.

It should be **stored** in small, completely-filled, well-closed bottles.

Standard.—Solution of ferrous phosphate contains not less than 14.1 per cent. and not more than 14.7 per cent. w/v of iron, calculated as $\text{Fe}_3(\text{PO}_4)_2$.

Assay.—Dilute about 1 gramme, accurately weighed, with about 50 millilitres of water and proceed by the method of the British Pharmacopœia for iron in Syrupus Ferri Phosphatis Compositus. From the specific gravity, calculate the percentage w/v.

Dose.—0.25 to 0.5 millilitre (4 to 8 minims).

LIQUOR FERRI PHOSPHATIS COMPOSITUS**(Liq. Ferr. Phosph. Co.)****Compound Solution of Ferrous Phosphate**

		<i>Metric</i>	<i>Imperial</i>
Iron	17.2 g.	150½ gr.
Phosphoric Acid	192.0 ml.	3 fl. oz. 403 m.
Calcium Carbonate	54.4 g.	1 oz. 38½ gr.
Potassium Bicarbonate	4.0 g.	35 gr.
Sodium Phosphate	4.0 g.	35 gr.
Cochineal	14.0 g.	122½ gr.
Triple Orange-flower Water	200.0 ml.	4 fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dilute 80 millilitres (1 fluid ounce 288 minims) of the phosphoric acid with 100 millilitres (2 fluid ounces) of distilled water, add the iron and heat gently until dissolved; triturate the calcium carbonate, potassium bicarbonate and sodium phosphate with the remainder of the phosphoric acid and 320 millilitres (6 fluid ounces 192 minims) of distilled water and add the solution containing the iron. Boil the

cochineal with 175 millilitres ($3\frac{1}{2}$ fluid ounces) of distilled water for fifteen minutes, cool, strain, add the triple orange-flower water, filter into the resulting liquid the solution containing the iron, calcium, potassium and sodium compounds, and pass sufficient distilled water through the filter to produce the required volume.

It should be **stored** in completely-filled bottles.

Standard.—Compound solution of ferrous phosphate, determined by the methods of the British Pharmacopœia for iron and for calcium in Syrupus Ferri Phosphatis Compositus, using about 5 grammes accurately weighed, contains not less than 3.5 per cent. and not more than 3.7 per cent. w/v of iron, calculated as $\text{Fe}_3(\text{PO}_4)_2$, and not less than 5.4 per cent. and not more than 5.8 per cent. w/v of calcium, calculated as $\text{Ca}_3(\text{PO}_4)_2$.

Dose.—0.5 to 2 millilitres (8 to 30 minims).

LIQUOR FORMALDEHYDI SAPONATUS

(Liq. Formaldehyd. Sap.)

Solution of Formaldehyde with Soap

	<i>Metric</i>	<i>Imperial</i>
Soft Soap	400 g.	8 oz.
Alcohol (90 per cent.) .. .	300 ml.	6 fl. oz.
Solution of Formaldehyde .. .	200 ml.	4 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Dissolve the soft soap in the alcohol, add the solution of formaldehyde and sufficient distilled water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR GUTTA PERCHA

(Liq. Gutt. Perch.)

Solution of Gutta Percha

Synonym—Traumaticin.

	<i>Metric</i>	<i>Imperial</i>
Gutta Percha, in thin slices .. .	100 g.	2 oz.
Chloroform .. .	900 g.	18 oz.

Add the gutta percha to the chloroform in a stoppered bottle and shake frequently, set aside until the insoluble matter has subsided, and decant the clear liquid.

It should be **stored** in well-stoppered bottles.

LIQUOR HAMAMELIDIS**(Liq. Hamam.)****Solution of Hamamelis***Synonym*—Distilled Witch Hazel.

	<i>Metric</i>	<i>Imperial</i>
Fresh Hamamelis Leaf	1000 g.	20 oz.
Distilled Water	2000 ml.	40 fl. oz.
Alcohol (90 per cent.)	160 ml.	3 fl. oz. 96 m.

Macerate for twenty-four hours and then distil 1000 millilitres (20 fluid ounces).

LIQUOR HYDRARGYRI NITRATIS ACIDUS**(Liq. Hydrarg. Nit. Acid.)****Acid Solution of Mercuric Nitrate**

	<i>Metric</i>	<i>Imperial</i>
Mercury	120 g.	4 oz.
Nitric Acid	150 ml.	5 fl. oz.
Distilled Water	45 ml.	1½ fl. oz.

Mix the nitric acid and the distilled water in a tared flask, and dissolve the mercury in the mixture without the application of heat; boil gently until the solution weighs 360 grammes (12 ounces).

It should be **stored** in well-stoppered bottles and protected from light.

LIQUOR IODI ÆTHEREUS**(Liq. Iod. Æther.)****Ethereal Solution of Iodine***Synonyms*—Tinctura Iodi Ætherica; Ethereal Tincture of Iodine.

	<i>Metric</i>	<i>Imperial</i>
Iodine	25 g.	½ oz.
Ether	to 1000 ml.	to 20 fl. oz.

Reduce the iodine to powder, dissolve it in about 900 millilitres (18 fluid ounces) of the ether, and add sufficient ether to produce the required volume.

LIQUOR IODI AQUOSUS

(Liq. Iod. Aq.)

Aqueous Solution of Iodine*Synonym*—Lugol's Solution.

	<i>Metric</i>	<i>Imperial</i>
Iodine	50 g.	1 oz.
Potassium Iodide	75 g.	1½ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the iodine and potassium iodide in about 100 millilitres (2 fluid ounces) of the distilled water, and add sufficient distilled water to produce the required volume.

Dose.—0·3 to 0·6 millilitres (5 to 10 minims).

LIQUOR IODI DECOLORATUS

(Liq. Iod. Decol.)

Decolourised Solution of Iodine*Synonyms*—Tinctura Iodi Decolorata; Decolourised Tincture of Iodine.

	<i>Metric</i>	<i>Imperial</i>
Iodine	28·6 g.	250 gr.
Strong Solution of Ammonia	62·5 ml.	1¼ fl. oz.
Alcohol (90 per cent.)	to 1000·0 ml.	to 20 fl. oz.

Dissolve the iodine in 275 millilitres (5½ fluid ounces) of the alcohol by the aid of gentle heat and add the strong solution of ammonia; keep the mixture in a warm place until decolourised, then add sufficient of the alcohol to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR IODI OLEOSUS

(Liq. Iod. Oleos.)

Oily Solution of Iodine*Synonyms*—Tinctura Iodi Oleosa; Oily Tincture of Iodine.

	<i>Metric</i>	<i>Imperial</i>
Iodine	80·0 g.	1 oz. 262½ gr.
Castor Oil	162·5 ml.	3¼ fl. oz.
Alcohol (90 per cent.)	to 1000·0 ml.	to 20 fl. oz.

Dissolve the iodine in 800 millilitres (16 fluid ounces) of the alcohol

by the aid of gentle heat; add the castor oil, and sufficient of the alcohol to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR KERATINI

(Liq. Keratin.)

Solution of Keratin

	<i>Metric</i>	<i>Imperial</i>
Keratin	90 g.	1 oz. 350 gr.
Strong Solution of Ammonia ..	455 ml.	9 fl. oz. 48 m.
Alcohol (90 per cent.)	455 ml.	9 fl. oz. 48 m.

Dissolve the keratin in the mixed liquids, and filter if necessary.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR MAGNESII CITRATIS

(Liq. Mag. Cit.)

Solution of Magnesium Citrate

Synonym—Limonade Purgative; Effervescing Solution of Magnesium and Potassium Citrates.

	<i>Metric</i>	<i>Imperial</i>
Heavy Magnesium Carbonate ..	40.0 g.	350 gr.
Citric Acid	90.0 g.	1 oz. 350 gr.
Syrup of Lemon	160.0 ml.	3 fl. oz. 96 m.
Potassium Bicarbonate, in crystals	7.5 g.	65½ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the citric acid in 200 millilitres (4 fluid ounces) of the distilled water, add the magnesium carbonate, and stir until dissolved. Filter the solution into the syrup of lemon contained in a strong bottle capable of holding 1000 millilitres (20 fluid ounces), add sufficient distilled water nearly to fill the bottle, then introduce the potassium bicarbonate and immediately close the bottle with a cork, which should be secured with string or wire; shake the bottle until the bicarbonate is dissolved.

It should be freshly prepared.

Dose.—100 to 300 millilitres (3 to 10 fluid ounces), or more.

LIQUOR MORPHINÆ ACETATIS

(Liq. Morph. Acet.)

Solution of Morphine Acetate

		<i>Metric</i>	<i>Imperial</i>
Morphine Acetate	10 g.	87½ gr.
Dilute Acetic Acid	20 ml.	192 m.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the alcohol with an equal volume of the distilled water and add the dilute acetic acid; dissolve the morphine acetate in the mixture, and add sufficient distilled water to produce the required volume.

Dose.—0.3 to 2 millilitres (5 to 30 minims).

LIQUOR MORPHINÆ TARTRATIS

(Liq. Morph. Tart.)

Solution of Morphine Tartrate

		<i>Metric</i>	<i>Imperial</i>
Morphine Tartrate	10 g.	87½ gr.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the alcohol with an equal volume of distilled water, dissolve the morphine tartrate in the mixture, and add sufficient distilled water to produce the required volume.

Dose.—0.3 to 2 millilitres (5 to 30 minims).

LIQUOR OPII SEDATIVUS

(Liq. Opii Sed.)

Sedative Solution of Opium

		<i>Metric</i>	<i>Imperial</i>
Opium, in small pieces	100.0 g.	2 oz.
Calcium Hydroxide	15.0 g.	131¼ gr.
Alcohol (90 per cent.)	200.0 ml.	4 fl. oz.
Sherry-type Wine	150.0 ml.	3 fl. oz.
Hydrochloric Acid	15.6 ml.	150 m.
Distilled Water	a sufficient quantity	
Alcohol (60 per cent.)	a sufficient quantity	

Macerate the opium with 250 millilitres (5 fluid ounces) of boiling water, allow to cool, add the calcium hydroxide, and digest in a closed vessel for two hours with frequent stirring. Strain, press, and repeat

the maceration with two further successive quantities each of 250 millilitres (5 fluid ounces) of cold distilled water. Mix the expressed liquids, add the above quantity of hydrochloric acid, or sufficient for 10 millilitres of the product to require for neutralisation to litmus paper 1 millilitre of N/1 solution of sodium hydroxide; add the alcohol (90 per cent.) and the sherry-type wine. Filter, determine the proportion of morphine in a portion of the product, and add to the remainder sufficient alcohol (60 per cent.) to produce a solution of the required strength.

Standard.—Sedative solution of opium, determined by the method of the British Pharmacopœia for 'Tinctura Opii, contains not less than 0·95 per cent. and not more than 1·05 per cent. w/v of morphine, calculated as anhydrous.

Dose.—0·3 to 2 millilitres (5 to 30 minims).

LIQUOR PANCREATINI

(Liq. Pancreatin.)

Solution of Pancreatin

Synonyms—Liquor Pancreatis; Pancreatic Solution.

		<i>Metric</i>	<i>Imperial</i>
Glycerin of Pancreatin	165 ml.	3 fl. oz.	144 m.
Sodium Bicarbonate	35 g.	306¼ gr.	
Glycerin	50 ml.	1 fl. oz.	
Alcohol (90 per cent.) .. .	150 ml.	3 fl. oz.	
Distilled Water	to 1000 ml.	to 20 fl. oz.	

Mix the glycerin of pancreatin with the sodium bicarbonate, glycerin, alcohol and sufficient distilled water to produce the required volume.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

LIQUOR PAPAINI ET IRIDINI

(Liq. Papain. et Iridin.)

Solution of Papain and Iridin

	<i>Metric</i>	<i>Imperial</i>
Papain	18·3 g.	160 gr.
Extract of Iris	18·3 g.	160 gr.
Glycerin	100·0 ml.	2 fl. oz.
Alcohol (90 per cent.) .. .	50·0 ml.	1 fl. oz.
Chloroform Water	to 1000·0 ml.	to 20 fl. oz.

Macerate the papain and extract of iris with the glycerin, alcohol and 800 millilitres (16 fluid ounces) of the chloroform water for seven days, with frequent agitation; filter, and add sufficient chloroform water to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

LIQUOR PEPTICUS

(Liq. Pept.)

Peptic Solution

	<i>Metric</i>	<i>Imperial</i>
Stronger Glycerin of Pepsin ..	125 ml.	2½ fl. oz.
Dilute Hydrochloric Acid ..	25 ml.	½ fl. oz.
Alcohol (90 per cent.) ..	100 ml.	2 fl. oz.
Glycerin	25 ml.	½ fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the stronger glycerin of pepsin, dilute hydrochloric acid, alcohol and glycerin, and add sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

LIQUOR PHENOLIS ALKALINUS

(Liq. Phenol. Alk.)

Alkaline Solution of Phenol*Synonym*—Solution of Sodium Phenate

	<i>Metric</i>	<i>Imperial</i>
Phenol	100 g.	2 oz.
Sodium Hydroxide	10 g.	87½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the sodium hydroxide in about 500 millilitres (10 fluid ounces) of the distilled water; dissolve the phenol in the solution and add sufficient distilled water to produce the required volume.

It should be **stored** in glass-stoppered bottles and protected from light.

For use as a mouthwash or gargle, this solution should be diluted with about 20 to 30 parts of water.

LIQUOR PHOSPHORI COMPOSITUS

(Liq. Phosphor. Co.)

Compound Solution of Phosphorus

Synonyms.—Tinctura Phosphori Composita; Compound Tincture of Phosphorus.

	<i>Metric</i>	<i>Imperial</i>
Phosphorus	2 g.	17½ gr.
Chloroform	175 ml.	3½ fl. oz.
Dehydrated Alcohol	to 1000 ml.	to 20 fl. oz.

Place the phosphorus and chloroform in a stoppered bottle and heat gently on a water-bath until solution is effected; add sufficient dehydrated alcohol to produce the required volume and shake well.

It should be **stored** in well-stoppered bottles and protected from light.

Dose.— 0.2 to 0.8 millilitre (3 to 12 minims).

LIQUOR POTASSII ARSENATIS ET BROMIDI

(Liq. Pot. Arsen. et Brom.)

Solution of Potassium Arsenate and Bromide*Synonyms*—Liquor Arsenii Bromidi; Clemens' Solution.

		<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	10 g.	87½ gr.
Potassium Bicarbonate	10 g.	87½ gr.
Bromine	5 ml.	48 m.
Distilled Waterto 1000 ml.	to 20 fl. oz.

Add the arsenic trioxide and potassium bicarbonate to 100 millilitres (2 fluid ounces) of distilled water and boil until dissolved; then add 700 millilitres (14 fluid ounces) of distilled water and the bromine, shake until dissolved, and add sufficient distilled water to produce the required volume.

Dose.—0·12 to 0·5 millilitre (2 to 8 minims).

LIQUOR POTASSII PERMANGANATIS

(Liq. Pot. Permang.)

Solution of Potassium Permanganate

		<i>Metric</i>	<i>Imperial</i>
Potassium Permanganate	10 g.	87½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.—8 to 16 millilitres (2 to 4 fluid drachms).

LIQUOR POTASSII PHENATIS COMPOSITUS

(Liq. Pot. Phenat. Co.)

Compound Solution of Potassium Phenate

Synonyms—Liquor Potassii Carbolatis Compositus; Compound Solution of Potassium Carbolate.

		<i>Metric</i>	<i>Imperial</i>
Liquefied Phenol	50·0 ml.	1 fl. oz.
Solution of Potassium Hydroxide	50·0 ml.	1 fl. oz.
Cologne Spirit	50·0 ml.	1 fl. oz.
Saccharin	0·1 g.	1 gr.
Tincture of Quillaia	25·0 ml.	½ fl. oz.
Emulsion of Chloroform	25·0 ml.	½ fl. oz.
Solution of Bordeaux B	4·2 ml.	40 m.
Triple Rose Water	to 1000·0 ml.	to 20 fl. oz.

Add the liquefied phenol to the solution of potassium hydroxide previously diluted with three times its volume of triple rose water,

dissolve the saccharin in the liquid, add the other ingredients and sufficient of the triple rose water to produce the required volume.

LIQUOR QUININÆ ET STRYCHNINÆ

(Liq. Quinin. et Strych.)

Solution of Quinine and Strychnine

		<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	118.4 g.	2 oz. 161 gr.
Strychnine Hydrochloride	2.4 g.	21 gr.
Hypophosphorous Acid	60.0 ml.	1 fl. oz. 96 m.
Glycerin	620.0 ml.	12 fl. oz. 192 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Triturate the quinine sulphate and the strychnine hydrochloride with a mixture of the glycerin and 225 millilitres ($4\frac{1}{2}$ fluid ounces) of distilled water; add the hypophosphorous acid, stir until the alkaloidal salts have dissolved, and add sufficient distilled water to produce the required volume.

It should be **stored** in completely-filled, well-closed bottles and protected from light.

Standard.—Solution of quinine and strychnine, determined by the methods of the British Pharmacopœia for quinine and for strychnine in Syrupus Ferri Phosphatis cum Quinina et Strychnina, using about 12.5 millilitres accurately weighed, contains not less than 8.5 per cent. and not more than 9.0 per cent. w/v of anhydrous quinine, and not less than 0.186 per cent. and not more than 0.206 per cent. w/v of strychnine.

A syrup differing from Syrupus Ferri Phosphatis cum Quinina et Strychnina only in the presence of 0.75 per cent. v/v of hypophosphorous acid may be made by mixing 1 fluid ounce of this solution, 1 fluid ounce of solution of ferrous phosphate, $\frac{1}{2}$ fluid ounce of glycerin and 1 fluid ounce of distilled water with sufficient syrup to produce 8 fluid ounces.

LIQUOR RHEI DULCIS

(Liq. Rhei Dulc.)

Sweet Solution of Rhubarb

Synonyms—Elixir Rhei; Elixir of Rhubarb; Sweet Essence of Rhubarb.

		<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Rhubarb	250.0 ml.	5 fl. oz.
Oil of Anise	0.5 ml.	5 m.
Syrup	225.0 ml.	$4\frac{1}{2}$ fl. oz.
Glycerin	150.0 ml.	3 fl. oz.
Alcohol (90 per cent.)	25.0 ml.	$\frac{1}{2}$ fl. oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Mix the liquid extract of rhubarb, syrup, glycerin and about 300 millilitres (6 fluid ounces) of distilled water, add the oil of anise dissolved in the alcohol, and sufficient distilled water to produce the required volume; filter if necessary.

Dose.—4 to 12 millilitres (1 to 3 fluid drachms).

LIQUOR RINGER

(Liq. Ringer)

Ringer's Solution

			<i>Metric</i>	<i>Imperial</i>
Sodium Chloride	7.0 g.	61 $\frac{1}{4}$ gr.
Potassium Chloride	0.14 g.	1 $\frac{9}{100}$ gr.
Calcium Chloride	0.12 g.	1 $\frac{1}{80}$ gr.
Sodium Bicarbonate	0.2 g.	1 $\frac{3}{4}$ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve. It may be sterilised by tyndallisation or by filtration.

This solution is isotonic with the serum of frogs' blood.

LIQUOR RINGER-LOCKE

(Liq. Ringer-Locke)

Ringer-Locke Solution

			<i>Metric</i>	<i>Imperial</i>
Sodium Chloride	9.0 g.	78 $\frac{3}{4}$ gr.
Potassium Chloride	0.42 g.	3 $\frac{7}{100}$ gr.
Calcium Chloride	0.24 g.	2 $\frac{1}{100}$ gr.
Dextrose	1.0 g.	8 $\frac{3}{4}$ gr.
Sodium Bicarbonate	0.5 g.	4 $\frac{3}{8}$ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve. It may be sterilised by tyndallisation or by filtration.

This solution is isotonic with the serum of mammalian blood.

LIQUOR RINGER-TYRODE

(Liq. Ringer-Tyrode)

Ringer-Tyrode Solution

			<i>Metric</i>	<i>Imperial</i>
Sodium Chloride	8.0 g.	70 gr.
Potassium Chloride	0.2 g.	1 $\frac{3}{4}$ gr.
Calcium Chloride	0.2 g.	1 $\frac{3}{4}$ gr.
Magnesium Chloride	0.01 g.	$\frac{7}{800}$ gr.
Dextrose	1.0 g.	8 $\frac{3}{4}$ gr.
Sodium Acid Phosphate	0.05 g.	$\frac{7}{16}$ gr.
Sodium Bicarbonate	1.0 g.	8 $\frac{3}{4}$ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve. It may be sterilised by tyndallisation or by filtration.

This solution is isotonic with the serum of mammalian blood.

LIQUOR ROSÆ DULCIS

(Liq. Ros. Dulc.)

Sweet Solution of Rose

	<i>Metric</i>	<i>Imperial</i>
Cochineal, in coarse powder	40·0 g.	350 gr.
Potassium Carbonate	40·0 g.	350 gr.
Potash Alum	40·0 g.	350 gr.
Potassium Acid Tartrate	40·0 g.	350 gr.
Glycerin	750·0 ml.	15 fl. oz.
Oil of Rose	0·25 ml.	2½ m.
Alcohol (90 per cent.)	1·5 ml.	14½ m.
Distilled Water	to 1000·0 ml.	to 20 fl. oz.

Triturate the cochineal with the potassium carbonate and 200 millilitres (4 fluid ounces) of water, add the potash alum and potassium acid tartrate successively, heat on a water-bath for one hour and filter into the glycerin; add the oil of rose dissolved in the alcohol, and then pass sufficient hot distilled water through the filter to produce the required volume.

LIQUOR SACCHARI USTI

(Liq. Sacch. Ust.)

Solution of Burnt Sugar

	<i>Metric</i>	<i>Imperial</i>
Burnt Sugar	500 ml.	10 fl. oz.
Chloroform Water	500 ml.	10 fl. oz.
Mix.		

LIQUOR SALOLIS COMPOSITUS

(Liq. Salol. Co.)

Compound Solution of Salol*Synonym*—Salol Mouth Wash.

	<i>Metric</i>	<i>Imperial</i>
Salol	25·0 g.	½ oz.
Thymol	2·5 g.	22 gr.
Oil of Anise	1·0 ml.	10 m.
Oil of Peppermint	5·0 ml.	48 m.
Elixir of Saccharin	25·0 ml.	½ fl. oz.
Alcohol (90 per cent.)	to 1000·0 ml.	to 20 fl. oz.

Dissolve the salol and thymol in 500 millilitres (10 fluid ounces) of the alcohol, heating gently if necessary; then add the oil of peppermint, oil

of anise, elixir of saccharin and sufficient of the alcohol to produce the required volume, and filter.

For use as a mouth-wash, a few drops are diluted with a wine-glassful of warm water.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR SANTALI COMPOSITUS

(Liq. Santal. Co.)

Compound Solution of Sandal Wood Oil

		<i>Metric</i>	<i>Imperial</i>
Oil of Sandal Wood	50.0 ml.	1 fl. oz.
Oil of Cinnamon	2.5 ml.	24 m.
Tincture of Buchu	170.0 ml.	3 fl. oz. 192 m.
Tincture of Cubeb	150.0 ml.	3 fl. oz.
Alcohol (90 per cent.)	.. to	1000.0 ml.	to 20 fl. oz.

Mix, and filter if necessary.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

LIQUOR SAPONIS ÆTHEREUS

(Liq. Sap. Æther.)

Ethereal Solution of Soap

Synonyms—Ether Soap; Solutio Saponis Ætherea.

		<i>Metric</i>	<i>Imperial</i>
Oleic Acid	350 ml.	7 fl. oz.
Potassium Hydroxide	a sufficient quantity	
Distilled Water	a sufficient quantity	
Alcohol (90 per cent.)	150 ml.	3 fl. oz.
Oil of Lavender	2 ml.	20 m.
Ether	to 1000 ml.	to 20 fl. oz.

Mix the oleic acid and alcohol and neutralise with a saturated solution of the potassium hydroxide in the distilled water (1 in 1), of which nearly 75 millilitres ($1\frac{1}{2}$ fluid ounces) will be required, using phenolphthalein as indicator. Allow the neutralised product to cool, add the oil of lavender and sufficient ether to produce the required volume.

It should be **stored** in well-stoppered bottles.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR SAPONIS ANTISEPTICUS

(Liq. Sap. Antisept.)

Antiseptic Solution of Soap*Synonyms*—Antiseptic Ethereal Soap; Solutio Saponis Antiseptica.

	<i>Metric</i>	<i>Imperial</i>
Mercuric Iodide	0.5 g.	4½ gr.
Potassium Iodide	0.5 g.	4½ gr.
Ethereal Solution of Soap	to 1000.0 ml.	to 20 fl. oz.

Dissolve.

LIQUOR SAPONIS OLEI COCOIS

(Liq. Sap. Ol. Coccois)

Solution of Coconut Oil Soap

	<i>Metric</i>	<i>Imperial</i>
Coconut Oil	183.1 g.	3 oz. 290 gr.
Potassium Hydroxide	19.7 g.	172 gr.
Sodium Hydroxide	19.7 g.	172 gr.
Thymol	a sufficient quantity	
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the sodium and potassium hydroxides in 200 millilitres (4 fluid ounces) of the distilled water, add the coconut oil, and set aside in a warm place until saponified; dissolve the soap in sufficient water to produce the required volume, allow to stand, separate the clear liquid, and saturate it with thymol.

LIQUOR SODÆ CHLORINATÆ

(Liq. Sod. Chlorinat.)

Solution of Chlorinated Soda

Solution of chlorinated soda is an aqueous solution of sodium hypochlorite containing a variable proportion of sodium chloride. It may be prepared by the electrolysis of sodium chloride solution, or by the following process :—

	<i>Metric</i>	<i>Imperial</i>
Chlorinated Lime	100 g.	2 oz.
Sodium Carbonate	150 g.	3 oz.
Distilled Water	1000 ml.	20 fl. oz.

Dissolve the sodium carbonate in 250 millilitres (5 fluid ounces) of the distilled water; thoroughly triturate the chlorinated lime with the remainder of the distilled water and mix the two liquids; shake occasionally during three or four hours, and filter.

It should be **stored** in well-stoppered bottles and protected from light.

Standard.—Solution of chlorinated soda contains not less than 2·5 per cent. and not more than 3 per cent. w/v of available chlorine.

Assay.—Add 5 millilitres to a solution of 1 gramme of potassium iodide in 100 millilitres of water acidified with 5 millilitres of hydrochloric acid, and titrate the liberated iodine with N/10 sodium thiosulphate; each millilitre of N/10 sodium thiosulphate is equivalent to 0·003546 gramme of available chlorine.

Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

LIQUOR SODÆ CHLORINATÆ CUM SODII BICARBONATE

(Liq. Sod. Chlorinat. c. Sod. Bicarb.)

Solution of Chlorinated Soda with Sodium Bicarbonate

Synonym—Daufresne's Solution.

Solution of chlorinated soda with sodium bicarbonate is prepared from finely-ground chlorinated lime, exsiccated sodium carbonate and sodium bicarbonate, the quantities being adjusted according to the proportion of available chlorine in the chlorinated lime, which must be determined immediately before use.

Percentage of available chlorine in the Chlorinated Lime	Quantities for 10 Litres of Solution		
	Chlorinated Lime	Exsiccated Sodium Carbonate	Sodium Bicarbonate
	Grammes	Grammes	Grammes
26	177	89	72
27	170	85	70
28	164	82	68
29	159	80	66
30	154	77	64
31	148	74	62
32	144	72	60
33	140	70	59
34	135	68	57
35	132	66	55
36	128	64	53
37	124	62	52

Weigh out the quantities of ingredients shown in the table. Shake the chlorinated lime with 5 litres of water in a 12 litre flask for five minutes, and allow to stand for six to twelve hours. Dissolve the sodium carbonate and bicarbonate separately in 5 litres of water, keeping the solution cold, and pour the solution into the suspension of chlorinated lime. Shake briskly, and set aside for thirty minutes. Siphon off the clear liquid, and filter through a double paper.

It should be **stored** in a cool place and protected from light.

Standard.—Solution of chlorinated soda with sodium bicarbonate, determined by the method for *Liquor Sodæ Chlorinatæ*, contains not less than 0.42 per cent. and not more than 0.48 per cent. w/v of available chlorine.

LIQUOR SODII ÆTHYLATIS

(*Liq. Sod. Æthylat.*)

Solution of Sodium Ethylate

	<i>Metric</i>	<i>Imperial</i>
Sodium, of commerce, clean and bright	50 g.	1 oz.
Dehydrated Alcohol	to 1000 ml.	to 20 fl. oz.

Dissolve cautiously in a flask cooled by a stream of cold water.

It should be recently prepared.

LIQUOR SODII ARSENATIS

(*Liq. Sod. Arsen.*)

Solution of Sodium Arsenate

	<i>Metric</i>	<i>Imperial</i>
Anhydrous Sodium Arsenate ..	10 g.	87½ gr.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve.

Standard.—Solution of sodium arsenate, determined by the method for *Sodii Arsenas Anhydrosus*, using 25 millilitres, contains not less than 0.95 per cent. and not more than 1.05 per cent. w/v of Na_2HAsO_4 .

Dose.—0.12 to 0.5 millilitre (2 to 8 minims).

LIQUOR SODII PHENATIS COMPOSITUS

(Liq. Sod. Phenat. Co.)

Compound Solution of Sodium Phenate*Synonyms*—Compound Solution of Sodium Carbolate; Phenol Soda.

	<i>Metric</i>	<i>Imperial</i>
Phenol	31·2 g.	273 gr.
Sodium Hydroxide	3·4 g.	30 gr.
Triple Orange-flower Water	250·0 ml.	5 fl. oz.
Triple Rose Water	125·0 ml.	2½ fl. oz.
Glycerin	125·0 ml.	2½ fl. oz.
Solution of Bordeaux B	50·0 ml.	1 fl. oz.
Distilled Water	to 1000·0 ml.	to 20 fl. oz.

Dissolve the phenol and the sodium hydroxide in 300 millilitres (6 fluid ounces) of the distilled water, add the other ingredients and sufficient distilled water to produce the required volume.

LIQUOR TARTRAZINÆ COMPOSITUS

(Liq. Tartrazin. Co.)

Compound Solution of Tartrazine*Synonym*—Liquor Flavus.

	<i>Metric</i>	<i>Imperial</i>
Tartrazine	7·5 g.	65½ gr.
Orange G	2·5 g.	22 gr.
Glycerin	250·0 ml.	5 fl. oz.
Chloroform Water	to 1000·0 ml.	to 20 fl. oz.

Dissolve the tartrazine and orange G in about 700 millilitres (14 fluid ounces) of the chloroform water, add the glycerin and sufficient chloroform water to produce the required volume.

LIQUOR THYMOLIS COMPOSITUS

(Liq. Thymol. Co.)

Compound Solution of Thymol*Synonyms*—Liquor Antisepticus; Antiseptic Solution.

	<i>Metric</i>	<i>Imperial</i>
Boric Acid	29·03 g.	254 gr.
Benzoic Acid	1·14 g.	10 gr.
Menthol	0·38 g.	3 gr.
Thymol	0·57 g.	5 gr.
Eucalyptol	1·25 ml.	12 m.
Oil of Peppermint	0·31 ml.	3 m.
Oil of Sweet Birch	0·31 ml.	3 m.
Oil of Thyme	0·31 ml.	3 m.
Tincture of Baptisia	50·00 ml.	1 fl. oz.
Alcohol (90 per cent.)	250·00 ml.	5 fl. oz.
Distilled Water	to 1000·00 ml.	to 20 fl. oz.

Dissolve the boric acid in 600 millilitres (12 fluid ounces) of the distilled water and add the benzoic acid dissolved in 150 millilitres (3 fluid ounces) of the alcohol. Dissolve the menthol, thymol, eucalyptol, oils of peppermint, sweet birch and thyme in the remainder of the alcohol, add the tincture of baptisia and 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin; shake vigorously, and add gradually, with constant shaking, the solution containing the acids. Allow the mixture to stand, with occasional shaking, for forty-eight hours; filter, and add sufficient distilled water to produce the required volume.

Dose.—0.3 to 2 millilitres (5 to 30 minims), largely diluted.

LIQUOR TINCTORIUM

(Liq. Tinctor.)

Solution of Brilliant Green and Crystal Violet

	<i>Metric</i>	<i>Imperial</i>
Brilliant Green	5 g.	43 $\frac{3}{4}$ gr.
Crystal Violet	5 g.	43 $\frac{3}{4}$ gr.
Alcohol (90 per cent.)	500 ml.	10 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the brilliant green and crystal violet in the alcohol and add sufficient distilled water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LIQUOR TOLUTANUS

(Liq. Tolu.)

Solution of Tolu

	<i>Metric</i>	<i>Imperial</i>
Balsam of Tolu	100 g.	2 oz.
Alcohol (90 per cent.)	300 ml.	6 fl. oz.
Sucrose	500 g.	10 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the balsam of tolu in the alcohol, add 100 grammes (2 ounces) of purified talc or kaolin and 350 millilitres (7 fluid ounces) of distilled water at a temperature of 70°; shake vigorously, and set aside for twenty-four hours; filter, dissolve the sucrose in the filtrate with the aid of gentle heat, and add sufficient distilled water to produce the required volume.

One volume of this solution diluted with seven volumes of syrup yields a syrup of tolu which is more aromatic than Syrupus Tolutanus.

LIQUOR TRINITROPHENOLIS

(Liq. Trinitrophen.)

Solution of Trinitrophenol*Synonyms*—Liquor Acidi Picrici; Solution of Picric Acid.

	<i>Metric</i>	<i>Imperial</i>
Trinitrophenol	50 g.	1 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

LIQUOR ZINCI CHLORIDI

(Liq. Zinc. Chlor.)

Solution of Zinc Chloride

	<i>Metric</i>	<i>Imperial</i>
Zinc, of commerce, granulated ..	400 g.	8 oz.
Hydrochloric Acid	1100 ml.	22 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the hydrochloric acid with 500 millilitres (10 fluid ounces) of distilled water in a porcelain dish, add the zinc, and heat gently until gas is no longer evolved; boil for half an hour, dilute, or evaporate if necessary, to 1000 millilitres (20 fluid ounces), and filter.

LOTIONES**Lotions**

Lotions are liquid preparations intended for application to the skin, or for aural, nasal, ophthalmic, oral, or urethral irrigation. They may be aqueous or alcoholic solutions, or suspensions in aqueous vehicles. The addition of alcohol hastens the drying and accentuates the cooling effect, whilst the addition of glycerin keeps the application moist for a considerable time. Mucilage of tragacanth is suitable for use in lotions when a suspending agent is required.

Lotions are used without friction, being applied on lint or other soft, absorbent fabric and covered with water-proof material, or dabbed on the skin with a camel-hair brush or cotton wool. Lotions intended for irrigation are used warm, and applied by means of special syringes or douches adapted to the purpose. All lotions should be dispensed in bottles distinguishable by touch from those in which medicaments for internal use are sent out, and they should be labelled "Not to be taken internally."

LOTIO ACIDI BORICI

(Lot. Acid. Boric.)

Boric Acid Lotion

			<i>Metric</i>	<i>Imperial</i>
Boric Acid	33.3 g.	291½ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.
Dissolve.				

LOTIO ACIDI SULPHUROSI

(Lot. Acid. Sulphuros.)

Lotion of Sulphurous Acid

			<i>Metric</i>	<i>Imperial</i>
Sulphurous Acid	250 ml.	5 fl. oz.
Glycerin of Tannic Acid	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.
Mix.				

LOTIO ACIDI TANNICI

(Lot. Acid. Tann.)

Lotion of Tannic Acid

			<i>Metric</i>	<i>Imperial</i>
Tannic Acid	20.0 g.	175 gr.
Mercuric Chloride	0.5 g.	4½ gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.
Dissolve.				

It should be freshly prepared.

LOTIO AMYGDALÆ AMARÆ

(Lot. Amygdal. Amar.)

Lotion of Bitter Almond*Synonyms*—Mistura Amygdalæ Amaræ; Bitter Almond Mixture.

			<i>Metric</i>	<i>Imperial</i>
Bitter Almond	75 g.	1½ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Blanch the bitter almond and triturate with a little of the distilled water to form a thin paste; gradually add sufficient distilled water to produce the required volume, and strain.

LOTIO BENZOINI

(Lot. Benzoin.)

Lotion of Benzoin*Synonym*—Lait Virginal.

			<i>Metric</i>	<i>Imperial</i>
Tincture of Benzoin	25 ml.	$\frac{1}{2}$ fl. oz.
Rose Water	to 1000 ml.	to 20 fl. oz.
Mix.				

In making this preparation the tincture of benzoin may be replaced by tincture of benzoin prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO CALAMINÆ

(Lot. Calamin.)

Calamine Lotion

			<i>Metric</i>	<i>Imperial</i>
Calamine	150 g.	3 oz.
Zinc Oxide	50 g.	1 oz.
Glycerin	50 ml.	1 fl. oz.
Rose Water	to 1000 ml.	to 20 fl. oz.

Triturate the calamine and zinc oxide with the glycerin and sufficient rose water to make a cream, and add sufficient rose water to produce the required volume.

LOTIO CANTHARIDINI

(Lot. Cantharidin.)

Cantharidin Lotion*Synonym*—Lotio Crinalis Stimulans.

			<i>Metric</i>	<i>Imperial</i>
Cantharidin	0.2 g.	$1\frac{3}{4}$ gr.
Acetone	50.0 ml.	1 fl. oz.
Castor Oil	200.0 ml.	4 fl. oz.
Alcohol (90 per cent.)	to 1000.0 ml.	to 20 fl. oz.

Dissolve the cantharidin in the acetone, add the castor oil and sufficient alcohol to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO EVAPORANS

(Lot. Evap.)

Evaporating Lotion

		<i>Metric</i>	<i>Imperial</i>
Alcohol (90 per cent.)	125.0 ml.	2½ fl. oz.
Ammonium Chloride	34.3 g.	300 gr.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the ammonium chloride in the alcohol and part of the distilled water and add sufficient distilled water to produce the required volume.

LOTIO HYDRARGYRI FLAVA

(Lot. Hydrarg. Flav.)

Yellow Mercurial Lotion*Synonym*—Yellow Wash.

		<i>Metric</i>	<i>Imperial</i>
Mercuric Chloride	4.6 g.	40 gr.
Solution of Calcium Hydroxide	..	1000.0 ml.	20 fl. oz.
Mix.			

LOTIO OLEI AMYGDALÆ AMMONIATA

(Lot. Ol. Amygdal. Ammon.)

Ammoniated Almond Oil Lotion*Synonyms*—Erasmus Wilson's Hair Lotion; Lotio Crinalis.

		<i>Metric</i>	<i>Imperial</i>
Almond Oil	125.0 ml.	2½ fl. oz.
Strong Solution of Ammonia	..	125.0 ml.	2½ fl. oz.
Oil of Rosemary	5.2 ml.	50 m.
Alcohol (90 per cent.)	500.0 ml.	10 fl. oz.
Honey Water	to 1000.0 ml.	to 20 fl. oz.

Mix the almond oil with the strong solution of ammonia and add the oil of rosemary, alcohol and sufficient honey water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO PHENOLIS

(Lot. Phenol.)

Phenol Lotion*Synonyms*—Lotio Acidi Carbolici; Carbolie Acid Lotion.

	<i>Metric</i>	<i>Imperial</i>
Phenol	12.5 g.	109½ gr.
Solution of Bordeaux B	1.0 ml.	10 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the phenol in warmed distilled water, cool, add the solution of bordeaux B and sufficient distilled water to produce the required volume.

LOTIO PICIS CARBONIS ALKALINA

(Lot. Pic. Carbon. Alk.)

Alkaline Lotion of Coal Tar

	<i>Metric</i>	<i>Imperial</i>
Solution of Coal Tar	20.8 ml.	200 m.
Sodium Bicarbonate	12.5 g.	¼ oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the sodium bicarbonate in about 900 millilitres (18 fluid ounces) of the distilled water, add the solution of coal tar and sufficient distilled water to produce the required volume.

LOTIO PICIS CARBONIS ET PLUMBI

(Lot. Pic. Carbon. et Plumb.)

Coal Tar and Lead Lotion

	<i>Metric</i>	<i>Imperial</i>
Solution of Coal Tar	31.2 ml.	300 m.
Strong Solution of Lead Subacetate	31.2 ml.	300 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Mix the strong solution of lead subacetate with about 900 millilitres (18 fluid ounces) of distilled water, add the solution of coal tar and sufficient distilled water to produce the required volume.

LOTIO PLUMBI CUM OPIO

(Lot. Plumb. c. Opio)

Lead and Opium Lotion

	<i>Metric</i>	<i>Imperial</i>
Tincture of Opium	50 ml.	1 fl. oz.
Dilute Solution of Lead Subacetate	to 1000 ml.	to 20 fl. oz.

Mix.

LOTIO PLUMBI EVAPORANS

(Lot. Plumb. Evap.)

Evaporating Lead Lotion

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Lead Subacetate	12.5 ml.	120 m.
Alcohol (90 per cent.)	200.0 ml.	4 fl. oz.
Distilled Water to	1000.0 ml.	to 20 fl. oz.

Mix.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO POTASSÆ SULPHURATÆ

(Lot. Potass. Sulphurat.)

Lotion of Sulphurated Potash*Synonym*—Lotio Zinci Sulphidi.

	<i>Metric</i>	<i>Imperial</i>
Sulphurated Potash	22.9 g.	200 gr.
Zinc Sulphate to	22.9 g.	200 gr.
Rose Water to	1000.0 ml.	to 20 fl. oz.

Dissolve the zinc sulphate in about 800 millilitres (16 fluid ounces) of the rose water, add the solution to the sulphurated potash previously powdered, and stir; then add sufficient rose water to produce the required volume.

LOTIO ROSÆ

(Lot. Ros.)

Rose Lotion

—Lac Rosæ; Milk of Roses.

	<i>Metric</i>	<i>Imperial</i>
Sweet Almond to	100.0 g.	2 oz.
Curd Soap to	6.9 g.	60 gr.
White Beeswax to	6.9 g.	60 gr.
Almond Oil to	6.2 ml.	60 m.
Oil of Bergamot to	6.2 ml.	60 m.
Oil of Lavender to	1.6 ml.	15 m.
Oil of Rose to	0.8 ml.	8 m.
Alcohol (90 per cent.)	150.0 ml.	3 fl. oz.
Rose Water to	1000.0 ml.	to 20 fl. oz.

Blanch the almonds and beat them with seven times their weight of rose water; add the resulting emulsion gradually to the curd soap, white

beeswax and almond oil, previously mixed by the aid of gentle heat; strain the emulsion, add the oils dissolved in the alcohol and sufficient rose water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO RUBRA

(Lot. Rub.)

Red Lotion

Synonym—Red Wash.

	<i>Metric</i>	<i>Imperial</i>
Zinc Sulphate	4.5 g.	39½ gr.
Compound Tincture of Lavender	20.8 ml.	200 m.
Distilled Water to 1000.0 ml.		to 20 fl. oz.

Dissolve.

LOTIO STAPHISAGRIÆ

(Lot. Staphisag.)

Stavesacre Lotion

Synonym—Nursery Hair Lotion.

	<i>Metric</i>	<i>Imperial</i>
Stavesacre, in coarse powder ..	100.0 g.	2 oz.
Acetic Acid	50.0 ml.	1 fl. oz.
Alcohol (90 per cent.)	100.0 ml.	2 fl. oz.
Oil of Geranium	0.2 ml.	2 m.
Oil of Lavender	0.2 ml.	2 m.
Oil of Lemon	0.4 ml.	4 m.
Glycerin	50.0 ml.	1 fl. oz.
Distilled Water to 1000.0 ml.		to 20 fl. oz.

Boil the stavesacre with the acetic acid and 800 millilitres (16 fluid ounces) of distilled water for ten minutes in a covered vessel, set aside until cold, then add the oils previously dissolved in the alcohol, filter, add the glycerin and sufficient distilled water to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO SULPHURIS

(Lot. Sulphur.)

Sulphur Lotion

	<i>Metric</i>	<i>Imperial</i>
Precipitated Sulphur	68.6 g.	1 oz. 162½ gr.
Alcohol (90 per cent.)	125.0 ml.	2½ fl. oz.
Glycerin	31.2 ml.	300 m.
Rose Water	400.0 ml.	8 fl. oz.
Solution of Calcium Hydroxide	to 1000.0 ml.	to 20 fl. oz.

Triturate the precipitated sulphur with the alcohol, glycerin and rose water to form a smooth cream, and add sufficient solution of calcium hydroxide to produce the required volume.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

LOTIO TRAGACANTHÆ

(Lot. Trag.)

Tragacanth Lotion*Synonym*—Lotio Emolliens.

	<i>Metric</i>	<i>Imperial</i>
Tragacanth, in powder	5.50 g.	48 gr.
Spirit of Chloroform	18.75 ml.	180 m.
Tincture of Tolu	18.75 ml.	180 m.
Cologne Spirit	25.00 ml.	½ fl. oz.
Glycerin	18.75 ml.	180 m.
Distilled Water	to 1000.00 ml.	to 20 fl. oz.

Shake the tragacanth with the spirit of chloroform, the tincture of tolu and the cologne spirit, add the glycerin and sufficient distilled water to produce the required volume, and shake vigorously.

LOTIO TRINITROPHENOLIS

(Lot. Trinitrophen.)

Lotion of Trinitrophenol*Synonyms*—Lotio Acidi Picrici; Picric Acid Lotion.

	<i>Metric</i>	<i>Imperial</i>
Trinitrophenol	10 g.	87½ gr.
Distilled Water .. .	to 1000 ml.	to 20 fl. oz.
Dissolve		

MISTURA ACIDI ACETYLSALICYLICI

(Mist. Acid. Acetylsalicyl.)

Mixture of Acetylsalicylic Acid*Synonym*—Aspirin Mixture.

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid	34.3 g.	300 gr.
Compound Powder of Tragacanth	22.9 g.	200 gr.
Chloroform Water to 1000.0 ml.		to 20 fl. oz.

Reduce the acetylsalicylic acid to fine powder and mix with the compound powder of tragacanth; add gradually, with constant trituration, sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA ACIDI ACETYLSALICYLICI COMPOSITA

(Mist. Acid. Acetylsalicyl. Co.)

Compound Mixture of Acetylsalicylic Acid*Synonym*—Compound Aspirin Mixture.

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid	34.3 g.	300 gr.
Potassium Citrate	68.6 g.	1 oz. 162½ gr.
Syrup of Lemon	41.7 ml.	400 m.
Chloroform Water to 1000.0 ml.		to 20 fl. oz.

Dissolve the potassium citrate in about 900 millilitres (18 fluid ounces) of the chloroform water and dissolve the acetylsalicylic acid in the solution: add the syrup of lemon and sufficient chloroform water to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA ACIDI PHOSPHORICI

(Mist. Acid. Phosph.)

Phosphoric Acid Mixture

	<i>Metric</i>	<i>Imperial</i>
Dilute Phosphoric Acid	31.2 ml.	300 m.
Emulsion of Chloroform	20.8 ml.	200 m.
Syrup of Orange	41.7 ml.	400 m.
Compound Infusion of Gentian. . to 1000.0 ml.		to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA ACIDI SULPHURICI CUM OPIO

(Mist. Acid. Sulph. c. Opio)

Sulphuric Acid Mixture with Opium

		<i>Metric</i>	<i>Imperial</i>
Dilute Sulphuric Acid	41.7 ml.	400 m.
Tincture of Opium	15.6 ml.	150 m.
Tincture of Capsicum	4.2 ml.	40 m.
Camphor Water to 1000.0 ml.		to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).**MISTURA ÆTHERIS CUM AMMONIA**

(Mist. Æther. c. Ammon.)

Ether Mixture with Ammonia

		<i>Metric</i>	<i>Imperial</i>
Spirit of Ether	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Aromatic Spirit of Ammonia	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Camphor Water to 1000.0 ml.		to 20 fl. oz.

Mix.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).**MISTURA ALBA**

(Mist. Alb.)

White Mixture

		<i>Metric</i>	<i>Imperial</i>
Light Magnesium Carbonate	45.7 g.	400 gr.
Magnesium Sulphate	274.3 g.	5 oz. 212 $\frac{1}{2}$ gr.
Peppermint Water to 1000.0 ml.		to 20 fl. oz.

Dissolve the magnesium sulphate in a sufficient quantity of the peppermint water, add the light magnesium carbonate, and sufficient peppermint water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA AMMONIACI

(Mist. Ammoniac.)

Ammoniacum Mixture

	<i>Metric</i>	<i>Imperial</i>
Ammoniacum	30 g.	262½ gr.
Syrup of Tolu	60 ml.	1 fl. oz. 96 m.
Distilled Water to 1000 ml.	to 20 fl. oz.

Crush the ammoniacum and triturate thoroughly with a little of the distilled water to form a thin paste; gradually add the remainder of the distilled water and the syrup of tolu, triturating until the mixture assumes a uniform milky appearance, and strain through fine muslin.

It should be freshly prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA AMMONIÆ CUM SENEGA

(Mist. Ammon. c. Seneg.)

Ammonia Mixture with Senega

	<i>Metric</i>	<i>Imperial</i>
Ammonium Carbonate	9·1 g.	80 gr.
Ammonium Chloride	11·4 g.	100 gr.
Tincture of Ipecacuanha	20·8 ml.	200 m.
Syrup of Tolu	62·5 ml.	1¼ fl. oz.
Infusion of Senega to 1000·0 ml.	to 20 fl. oz.

Dissolve the ammonium carbonate and the ammonium chloride in a portion of the infusion, add the tincture of ipecacuanha, syrup of tolu and sufficient infusion of senega to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA AMMONII ACETATIS COMPOSITA

(Mist. Ammon. Acet. Co.)

Compound Ammonium Acetate Mixture*Synonym*—Mistura Diaphoretica.

	<i>Metric</i>	<i>Imperial</i>
Potassium Citrate	45·7 g.	400 gr.
Strong Solution of Ammonium Acetate	41·7 ml.	400 m.
Spirit of Nitrous Ether	41·7 ml.	400 m.
Spirit of Chloroform	41·7 ml.	400 m.
Camphor Water to 1000·0 ml.	to 20 fl. oz.

Dissolve the potassium citrate in about 500 millilitres (10 fluid ounces) of the camphor water, add the other ingredients and sufficient camphor water to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA AMYGDALÆ

(Mist. Amygdal.)

Almond Mixture

	<i>Metric</i>	<i>Imperial</i>
Compound Powder of Almond	125 g.	2 $\frac{1}{2}$ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Triturate the powder with a little of the distilled water to form a thin paste; gradually add the remainder of the distilled water and strain through fine muslin.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA BISMUTHI COMPOSITA

(Mist. Bism. Co.)

Compound Bismuth Mixture

	<i>Metric</i>	<i>Imperial</i>
Concentrated Solution of Bismuth	500.0 ml.	10 fl. oz.
Chloroform	8.3 ml.	80 m.
Tincture of Nux Vomica ..	125.0 ml.	2 $\frac{1}{2}$ fl. oz.
Dilute Hydrocyanic Acid ..	33.4 ml.	320 m.
Solution of Bordeaux B ..	20.8 ml.	200 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dilute the concentrated solution of bismuth with half its volume of water and add the chloroform dissolved in the tincture of nux vomica; filter if necessary through purified talc or kaolin, add the dilute hydrocyanic acid and the solution of bordeaux B, and pass sufficient distilled water through the filter to produce the required volume.

It should be recently prepared.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MISTURA BISMUTHI COMPOSITA ACIDA CUM PEPSINO

(Mist. Bism. Co. Acid. c. Pepsin.)

Compound Acid Mixture of Bismuth with Pepsin

	<i>Metric</i>	<i>Imperial</i>
Acid Solution of Bismuth ..	350.0 ml.	7 fl. oz.
Pepsin	18.3 g.	160 gr.
Liquid Extract of Nux Vomica ..	10.4 ml.	100 m.
Dilute Hydrocyanic Acid ..	33.4 ml.	320 m.
Solution of Bordeaux B ..	20.8 ml.	200 m.
Double Chloroform Water .. to	1000.0 ml.	to 20 fl. oz.

Dissolve the pepsin in about 500 millilitres (10 fluid ounces) of double chloroform water and add the acid solution of bismuth and the liquid extract of nux vomica; filter if necessary and add the solution of bordeaux B, the dilute hydrocyanic acid and sufficient double chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MISTURA BISMUTHI COMPOSITA CUM PEPSINO

(Mist. Bism. Co. c. Pepsin.)

Compound Bismuth Mixture with Pepsin

	<i>Metric</i>	<i>Imperial</i>
Concentrated Solution of Bismuth	500.0 ml.	10 fl. oz.
Pepsin	18.3 g.	160 gr.
Chloroform	8.3 ml.	80 m.
Tincture of Nux Vomica ..	125.0 ml.	2½ fl. oz.
Dilute Hydrocyanic Acid ..	33.4 ml.	320 m.
Solution of Bordeaux B ..	20.8 ml.	200 m.
Distilled Water to	1000.0 ml.	to 20 fl. oz.

Dissolve the pepsin in 250 millilitres (5 fluid ounces) of distilled water and add the solution to the concentrated solution of bismuth; add the chloroform dissolved in the tincture of nux vomica and, if necessary, filter through purified talc or kaolin; add the dilute hydrocyanic acid and the solution of bordeaux B, and pass sufficient distilled water through the filter to produce the required volume.

It should be recently prepared.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MISTURA BISMUTHI COMPOSITA CUM PEPSINO ET MORPHINA

(Mist. Bism. Co. c. Pepsin. et Morph.)

Compound Bismuth Mixture with Pepsin and Morphine

	<i>Metric</i>	<i>Imperial</i>
Morphine Hydrochloride ..	0.46 g.	4 gr.
Compound Bismuth Mixture with Pepsin to 1000.0 ml.	to 20 fl. oz.

Dissolve.

It should be recently prepared.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MISTURA BISMUTHI ET MAGNESII HYDROXIDUM

(Mist. Bism. et Mag. Hydrox.)

Mixture of Bismuth and Magnesium Hydroxides

	<i>Metric</i>	<i>Imperial</i>
Mixture of Bismuth Hydroxide	500 ml.	10 fl. oz.
Mixture of Magnesium Hydroxide	500 ml.	10 fl. oz.

Mix.

It should be **stored** in well-closed bottles and protected from light.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

MISTURA BISMUTHI ET PANCREATINI

(Mist. Bism. et Pancreatin.)

Mixture of Bismuth and Pancreatin

	<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	22.9 g.	200 gr.
Sodium Bicarbonate . . .	22.9 g.	200 gr.
Pancreatin	9.14 g.	80 gr.
Dilute Hydrocyanic Acid ..	4.17 ml.	40 m.
Chloroform Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the pancreatin in a portion of the chloroform water, add the other ingredients and sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA BISMUTHI ET SODII BICARBONATIS

(Mist. Bism. et Sod. Bicarb.)

Bismuth and Sodium Bicarbonate Mixture*Synonyms*—Mistura Bismuthi cum Soda; Bismuth and Soda Mixture.

			<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	22.9 g.	200 gr.
Sodium Bicarbonate	22.9 g.	200 gr.
Light Magnesium Carbonate	22.9 g.	200 gr.
Glycerin	50.0 ml.	1 fl. oz.
Distilled Waterto 1000.0 ml.	to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).**MISTURA BISMUTHI HYDROXIDI**

(Mist. Bism. Hydrox.)

Mixture of Bismuth Hydroxide*Synonym*—Magma Bismuthi.

			<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate	125 g.	2½ oz.
Nitric Acid	90 ml.	1 fl. oz. 384 m.
Sodium Hydroxide	90 g.	1 oz. 350 gr.
Distilled Waterto 1000 ml.	to 20 fl. oz.

Mix the bismuth subnitrate with 75 millilitres ($1\frac{1}{2}$ fluid ounces) of distilled water, add the nitric acid and warm gently until the bismuth subnitrate is dissolved. Dissolve the sodium hydroxide in 5000 millilitres (5 pints) of water and add the bismuth solution in one quantity, stirring rapidly. Allow the precipitate to subside and pour off the clear liquid; collect the precipitate on a calico strainer and wash with water, maintaining a layer of liquid above the precipitate, until the washings are neutral to phenolphthalein; allow the residue to drain and mix it with sufficient distilled water to produce the required volume.

It should be **stored** in well-closed bottles and protected from light.

Standard.—Mixture of bismuth hydroxide yields, on evaporating to dryness and igniting the residue to constant weight, not less than 9 per cent. and not more than 11 per cent. w/v of Bi_2O_3 . To 1 millilitre of a 5 per cent. v/v dilution add 5 drops of phenoldisulphonic acid solution and evaporate to dryness on a water-bath; add 10 millilitres of dilute solution of ammonia, filter, and wash the precipitate with water until

the mixed filtrate and washings measure 100 millilitres. The colour of the resulting liquid is not deeper than that obtained by similarly treating 1 millilitre of a 0.01 per cent. w/v solution of potassium nitrate (limit of nitrate).

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

MISTURA BROMIDI COMPOSITA

(Mist. Brom. Co.)

Compound Mixture of Bromides

	<i>Metric</i>	<i>Imperial</i>
Ammonium Bromide	22.9 g.	200 gr.
Potassium Bromide	22.9 g.	200 gr.
Sodium Bromide	22.9 g.	200 gr.
Tincture of Nux Vomica	20.8 ml.	200 m.
Solution of Carmine	3.1 ml.	30 m.
Glycerin	62.5 ml.	1½ fl. oz.
Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the bromides in about 500 millilitres (10 fluid ounces) of the chloroform water; add the tincture of nux vomica, solution of carmine, glycerin and sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA CASCARÆ COMPOSITA

(Mist. Casc. Co.)

Compound Mixture of Cascara

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Cascara Sagrada	41.7 ml.	400 m.
Liquid Extract of Liquorice	62.5 ml.	1½ fl. oz.
Tincture of Belladonna	10.4 ml.	100 m.
Tincture of Nux Vomica	10.4 ml.	100 m.
Aromatic Spirit of Ammonia	41.7 ml.	400 m.
Glycerin	62.5 ml.	1½ fl. oz.
Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA CHLOROFORMI COMPOSITA

(Mist. Chlorof. Co.)

Compound Chloroform Mixture*Synonyms*—Mistura Tussi Sedativa; Mistura Tussi Rubra.

	<i>Metric</i>	<i>Imperial</i>
Morphine Hydrochloride ..	0.9 g.	8 gr.
Dilute Hydrobromic Acid ..	250.0 ml.	5 fl. oz.
Chloroform	4.2 ml.	40 m.
Solution of Bordeaux B ..	20.8 ml.	200 m.
Cherry-laurel Water ..	250.0 ml.	5 fl. oz.
Syrup of Tolu	250.0 ml.	5 fl. oz.
Syrup to 1000.0 ml.	to 20 fl. oz.

Dissolve the morphine hydrochloride in the cherry-laurel water, add the syrup of tolu and dilute hydrobromic acid, then add the solution of bordeaux B, chloroform and sufficient syrup to produce the required volume, and shake until the chloroform is dissolved.

It should be recently prepared.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

MISTURA CRETÆ

(Mist. Cret.)

Chalk Mixture

	<i>Metric</i>	<i>Imperial</i>
Chalk	30 g.	262 $\frac{1}{2}$ gr.
Tragacanth, in powder ..	5 g.	43 $\frac{3}{4}$ gr.
Sucrose	60 g.	1 oz. 87 $\frac{1}{2}$ gr.
Cinnamon Water to 1000 ml.	to 20 fl. oz.

Triturate the chalk with the tragacanth and sucrose and add gradually, with constant trituration, sufficient cinnamon water to produce the required volume.

It should be freshly prepared.

Dose.—15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA CRETÆ COMPOSITA

(Mist. Cret. Co.)

Compound Chalk Mixture

	<i>Metric</i>	<i>Imperial</i>
Aromatic Powder of Chalk ..	20.57 g.	180 gr.
Chalk	20.57 g.	180 gr.
Tragacanth, in powder ..	4.57 g.	40 gr.
Sucrose	50.00 g.	1 oz.
Aromatic Spirit of Ammonia ..	18.75 ml.	180 m.
Tincture of Catechu ..	62.50 ml.	1 $\frac{1}{4}$ fl. oz.
Compound Tincture of Cardamom	37.50 ml.	360 m.
Tincture of Opium	6.25 ml.	60 m.
Cinnamon Water to 1000.00 ml.	to 20 fl. oz.

Triturate the chalk with the tragacanth and the other powders, and gradually add, with constant trituration, sufficient cinnamon water to produce about 500 millilitres (10 fluid ounces); then add the tinctures and the aromatic spirit of ammonia, previously mixed together, and sufficient cinnamon water to produce the required volume.

It should be recently prepared.

Dose.— 30 millilitres (1 fluid ounce) for an adult; 15 millilitres ($\frac{1}{2}$ fluid ounce) for a child twelve years old; 8 millilitres (2 fluid drachms) for a child seven years old.

MISTURA DAMIANÆ COMPOSITA

(Mist. Damian. Co.)

Compound Damiana Mixture

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Damiana ..	250.0 ml.	5 fl. oz.
Liquid Extract of Nux Vomica ..	16.7 ml.	160 m.
Calcium Hypophosphite ..	45.7 g.	400 gr.
Sodium Hypophosphite ..	45.7 g.	400 gr.
Chloroform Water to	1000.0 ml.	to 20 fl. oz.

Dissolve the calcium and sodium hypophosphites in 600 millilitres (12 fluid ounces) of chloroform water, add the liquid extracts, mix, and add sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

MISTURA FERRI COMPOSITA

(Mist. Ferr. Co.)

Compound Iron Mixture

Synonym—Griffith's Mixture.

	<i>Metric</i>	<i>Imperial</i>
Ferrous Sulphate, in powder ..	6 g.	52 $\frac{1}{2}$ gr.
Potassium Carbonate ..	8 g.	70 gr.
Myrrh	15 g.	131 $\frac{1}{4}$ gr.
Acacia, in powder	15 g.	131 $\frac{1}{4}$ gr.
Liquid Glucose	15 g.	131 $\frac{1}{4}$ gr.
Spirit of Nutmeg	10 ml.	96 m.
Rose Water to	1000 ml.	to 20 fl. oz.

Crush the myrrh, add the potassium carbonate, liquid glucose and acacia, and triturate the mixture with a small quantity of rose water to form a thin paste; gradually add more rose water and the spirit of nutmeg, continuing the trituration and further addition of rose water until 1000 millilitres (20 fluid ounces) of liquid is produced; add the ferrous sulphate and shake until dissolved.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA FERRI CUM MALTO

(Mist. Ferr. c. Malt.)

Mixture of Iron with Malt

	<i>Metric</i>	<i>Imperial</i>
Soluble Iron Pyrophosphate ..	54.9 g.	1 oz. 42½ gr.
Distilled Water	50.0 ml.	1 fl. oz.
Liquid Extract of Malt to 1000.0 ml.	to 20 fl. oz.

Dissolve the soluble iron pyrophosphate in the distilled water and add sufficient liquid extract of malt to produce the required volume.

It should be recently prepared.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

MISTURA GENTIANÆ ACIDA

(Mist. Gent. Acid.)

Acid Gentian Mixture

	<i>Metric</i>	<i>Imperial</i>
Dilute Nitro-hydrochloric Acid	25.0 ml.	½ fl. oz.
Compound Infusion of Gentian	500.0 ml.	10 fl. oz.
Syrup of Orange	62.5 ml.	1¼ fl. oz.
Chloroform Water to 1000.0 ml.	to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA GENTIANÆ ALKALINA

(Mist. Gent. Alk.)

Alkaline Gentian Mixture

Synonym—Mistura Gentianæ cum Soda.

	<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	34.3 g.	300 gr.
Ammonium Carbonate	11.4 g.	100 gr.
Syrup of Orange	62.5 ml.	1¼ fl. oz.
Compound Infusion of Gentian	to 1000.0 ml.	to 20 fl. oz.

Dissolve the sodium bicarbonate and ammonium carbonate in about 500 millilitres (10 fluid ounces) of the compound infusion of gentian, add the syrup of orange and sufficient compound infusion of gentian to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MISTURA GUAIACI

(Mist. Guaiac.)

Guaiacum Mixture

	<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin	25 g.	$\frac{1}{2}$ oz.
Sucrose	25 g.	$\frac{1}{2}$ oz.
Tragacanth, in powder	5 g.	43 $\frac{3}{4}$ gr.
Cinnamon Water	to 1000 ml.	to 20 fl. oz.

Triturate the guaiacum resin, sucrose and tragacanth with sufficient cinnamon water, added gradually, to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA IPECACUANHÆ COMPOSITA

(Mist. Ipecac. Co.)

Compound Ipecacuanha Mixture*Synonym*—Mistura Expectorans.

	<i>Metric</i>	<i>Imperial</i>
Vinegar of Ipecacuanha	50.0 ml.	1 fl. oz.
Strong Solution of Ammonium		
Acetate	31.2 ml.	300 m.
Oxymel of Squill	31.2 ml.	300 m.
Glycerin	83.3 ml.	1 fl. oz. 320 m.
Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Mix.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA LOBELIÆ ET STRAMONII COMPOSITA

(Mist. Lobel. et Stramon. Co.)

Compound Mixture of Lobelia and Stramonium

	<i>Metric</i>	<i>Imperial</i>
Ammonium Carbonate	9.1 g.	80 gr.
Potassium Iodide	11.4 g.	100 gr.
Ethereal Tincture of Lobelia ..	20.8 ml.	200 m.
Tincture of Stramonium	20.8 ml.	200 m.
Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the ammonium carbonate and potassium iodide in part of the chloroform water; add the tinctures and sufficient chloroform water to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA MAGNESII HYDROXIDI ET PARAFFINI LIQUIDI

(Mist. Mag. Hydrox. et Paraff. Liq.)

Mixture of Magnesium Hydroxide and Liquid Paraffin

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	300.0 ml.	6 fl. oz.
Vanillin, in powder	0.03 g.	$\frac{1}{4}$ gr.
Mixture of Magnesium Hydroxide	700.0 ml.	14 fl. oz.

Triturate the vanillin with the liquid paraffin, add the mixture of magnesium hydroxide and emulsify by means of a homogenising machine or, alternatively, by means of 75 grammes ($1\frac{1}{2}$ ounces) of acacia in powder triturated first with the liquid paraffin.

It should be recently prepared.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

MISTURA OLEI RICINI

(Mist. Ol. Ricin.)

Castor Oil Mixture

	<i>Metric</i>	<i>Imperial</i>
Castor Oil	375 ml.	$7\frac{1}{2}$ fl. oz.
Acacia, in powder	100 g.	2 oz.
Triple Orange-flower water	150 ml.	3 fl. oz.
Cinnamon Water	to 1000 ml.	to 20 fl. oz.

Triturate quickly the castor oil with the acacia; without delay add, in one quantity, 200 millilitres (4 fluid ounces) of cinnamon water and stir briskly until emulsified; then add, with constant trituration, the orange-flower water and sufficient cinnamon water to produce the required volume.

It should be freshly prepared.

Dose (as a single draught).—30 to 60 millilitres (1 to 2 fluid ounces).

MISTURA POTASSII ACETATIS COMPOSITA

(Mist. Pot. Acet. Co.)

Compound Potassium Acetate Mixture

Synonym—Mistura Diuretica.

	<i>Metric</i>	<i>Imperial</i>
Potassium Acetate	45.7 g.	400 gr.
Spirit of Nitrous Ether	62.5 ml.	$1\frac{1}{4}$ fl. oz.
Tincture of Hyoscyamus	41.7 ml.	400 m.
Juice of Scopolium	125.0 ml.	$2\frac{1}{8}$ fl. oz.
Infusion of Buchu	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium acetate in about 500 millilitres (10 fluid ounces) of the infusion of buchu, add the other ingredients and sufficient infusion of buchu to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA QUININÆ SALICYLATIS

(Mist. Quinin. Salicyl.)

Mixture of Quinine Salicylate

	<i>Metric</i>	<i>Imperial</i>
Ammoniated Solution of Quinine	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Potassium Citrate	22.9 g.	200 gr.
Sodium Salicylate	22.9 g.	200 gr.
Glycerin	125.0 ml.	2 $\frac{1}{2}$ fl. oz.
Compound Infusion of Gentian	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium citrate and sodium salicylate in about 750 millilitres (15 fluid ounces) of the compound infusion of gentian, add the ammoniated solution of quinine and glycerin, previously mixed, and sufficient compound infusion of gentian to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA RHEI ET CASCARÆ

(Mist. Rhei et Casc.)

Rhubarb and Cascara Mixture

	<i>Metric</i>	<i>Imperial</i>
Rhubarb, in powder	9.1 g.	80 gr.
Sodium Bicarbonate	27.4 g.	240 gr.
Liquid Extract of Liquorice ..	31.2 ml.	300 m.
Liquid Extract of Cascara Sagrada	41.7 ml.	400 m.
Syrup of Ginger	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Oil of Peppermint	1.6 ml.	15 m.
Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Triturate the rhubarb and sodium bicarbonate with the oil of peppermint and the syrup of ginger; add gradually, with constant trituration, the liquid extract of liquorice, the liquid extract of cascara sagrada and sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA RHEI ET SODII BICARBONATIS

(Mist. Rhei et Sod. Bicarb.)

Rhubarb and Sodium Bicarbonate Mixture*Synonyms*—Mistura Rhei Composita; Mistura Rhei et Sodæ.

		<i>Metric</i>	<i>Imperial</i>
Rhubarb, in powder	9.1 g.	80 gr.
Sodium Bicarbonate	27.4 g.	240 gr.
Syrup of Ginger	62.5 ml.	1½ fl. oz.
Oil of Peppermint	1.6 ml.	15 m.
Chloroform Water to 1000.0 ml.		to 20 fl. oz.

Triturate the rhubarb and sodium bicarbonate with the oil of peppermint and the syrup of ginger, and add gradually, with constant trituration, sufficient chloroform water to produce the required volume.

It should be recently prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA SODII BICARBONATIS AROMATICA

(Mist. Sod. Bicarb. Aromat.)

Aromatic Sodium Bicarbonate Mixture*Synonyms*—Mistura Carminativa; Carminative Mixture.

		<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	22.9 g.	200 gr.
Aromatic Spirit of Ammonia	25.0 ml.	½ fl. oz.
Compound Tincture of Cardamom	50.0 ml.	1 fl. oz.
Glycerin	75.0 ml.	1½ fl. oz.
Dill Water to 1000.0 ml.		to 20 fl. oz.

Dissolve the sodium bicarbonate in about 800 millilitres (16 fluid ounces) of dill water, add the aromatic spirit of ammonia, compound tincture of cardamom, glycerin and sufficient dill water to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

MISTURA SPIRITUS VINI GALLICI

(Mist. Sp. Vin. Gall.)

Mixture of Brandy

		<i>Metric</i>	<i>Imperial</i>
Brandy	456 ml.	8 fl. oz.
Cinnamon Water	456 ml.	8 fl. oz.
Sucrose	57 g.	1 oz.
Yolk of Egg	114 ml.	2 fl. oz.

Triturate together the yolk of egg and sucrose, add the cinnamon water and brandy, and mix.

It should be freshly prepared.

Dose (as a draught).— 30 to 60 millilitres (1 to 2 fluid ounces).

MISTURA VALERIANÆ COMPOSITA

(Mist. Valerian. Co.)

Compound Valerian Mixture

	<i>Metric</i>	<i>Imperial</i>
Potassium Bromide	22.9 g.	200 gr.
Ammoniated Tincture of Valerian	62.5 ml.	1½ fl. oz.
Camphor Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium bromide in a portion of the camphor water, add the ammoniated tincture of valerian and sufficient camphor water to produce the required volume.

It should be freshly prepared.

Dose.— 15 to 30 millilitres (½ to 1 fluid ounce).

MUCILAGO LINI

(Mucil. Lini)

Mucilage of Linseed

	<i>Metric</i>	<i>Imperial</i>
Linseed	125 g.	2½ oz.
Distilled Water, boiling	1000 ml.	20 fl. oz.

Infuse the linseed in the water for fifteen minutes and strain.

It should be freshly prepared.

NEBULÆ

Sprays

Sprays are solutions of medicaments in aqueous, oily, alcoholic, or glycerinated media, intended to be applied to the nose or throat by means of an atomiser. The choice of atomiser depends on the viscosity of the liquid; a spray made with an oily vehicle needs a more powerful

atomiser than one made with water or alcohol. Medicaments should be completely dissolved and should not be suspended. Paraffinum Liquidum Leve is more suitable than Paraffinum Liquidum for the preparation of sprays.

NEBULA ADRENALINÆ AROMATICA

(Neb. Adrenal. Aromat.)

Aromatic Adrenaline Spray

Synonyms—Adrenaline Inhalant; Aromatic Solution of Adrenaline.

			<i>Metric</i>	<i>Imperial</i>
Adrenaline	1 g.	8 $\frac{1}{4}$ gr.
Dehydrated Alcohol	125 ml.	2 $\frac{1}{2}$ fl. oz.
Hydrochloric Acid	a sufficient quantity	
Eucalyptol	50 ml.	1 fl. oz.
Oil of Sweet Birch	20 ml.	192 m.
Castor Oil	500 ml.	10 fl. oz.
Arachis Oil to 1000 ml.	to 20 fl. oz.

Add the adrenaline to the dehydrated alcohol and very cautiously add just sufficient hydrochloric acid, approximately 0·8 millilitre (8 minims), to dissolve it; the acid may be conveniently applied by means of a glass rod dipped alternately into the acid and the alcoholic solution, and shaking the mixture after each addition of acid. When solution of the adrenaline is complete, mix with the castor oil, then add the eucalyptol, oil of sweet birch and sufficient arachis oil to produce the required volume.

It should be **stored** in completely-filled, well-closed bottles, and protected from light.

NEBULA ADRENALINÆ ET COCAINÆ

(Neb. Adrenal. et Cocain.)

Adrenaline and Cocaine Spray

			<i>Metric</i>	<i>Imperial</i>
Solution of Adrenaline Hydrochloride	200·0 ml.	4 fl. oz.
Cocaine Hydrochloride	10·0 g.	87 $\frac{1}{2}$ gr.
Chlorbutol	4·0 g.	35 gr.
Sodium Chloride	7·2 g.	63 gr.
Distilled Water to 1000·0 ml.	to 20 fl. oz.

Dissolve the cocaine hydrochloride, chlorbutol and sodium chloride in part of the distilled water, add the solution of adrenaline hydrochloride and sufficient distilled water to produce the required volume.

NEBULA ADRENALINÆ ET EPHEDRINÆ

(Neb. Adrenal. et Ephed.)

Adrenaline and Ephedrine Spray

	<i>Metric</i>	<i>Imperial</i>
Solution of Adrenaline Hydrochloride	125.0 ml.	2½ fl. oz.
Ephedrine Hydrochloride	22.9 g.	200 gr.
Glycerin of Phenol	20.8 ml.	200 m.
Cinnamon Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the ephedrine hydrochloride in part of the cinnamon water, add the solution of adrenaline hydrochloride, the glycerin of phenol and sufficient cinnamon water to produce the required volume.

NEBULA ADRENALINÆ ET EPHEDRINÆ OLEOSA

(Neb. Adrenal. et Ephed. Oleos.)

Oily Adrenaline and Ephedrine Spray

	<i>Metric</i>	<i>Imperial</i>
Adrenaline .. .	0.1 g.	1 gr.
Ephedrine	20.0 g.	175 gr.
Dehydrated Alcohol .. .	125.0 ml.	2½ fl. oz.
Hydrochloric Acid .. .	a sufficient	quantity
Menthol	20.0 g.	175 gr.
Eucalyptol .. .	8.0 ml.	77 m.
Castor Oil	500.0 ml.	10 fl. oz.
Arachis Oil to 1000.0 ml.	to 20 fl. oz.

Add the adrenaline to the dehydrated alcohol and very cautiously add just sufficient hydrochloric acid to dissolve it; the acid may be conveniently applied by means of a glass rod dipped alternately into the acid and the alcoholic solution, and shaking the mixture after each addition of acid. Dissolve the ephedrine, menthol and eucalyptol in the alcoholic liquid, mix with the castor oil and add sufficient arachis oil to produce the required volume.

It should be recently prepared and **stored** in completely-filled, well-closed bottles and protected from light.

NEBULA ALKALINA COMPOSITA

(Neb. Alk. Co.)

Compound Alkaline Spray

	<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	15.0 g.	131½ gr.
Borax	15.0 g.	131½ gr.
Phenol	7.5 g.	65½ gr.
Glycerin	250.0 ml.	5 fl. oz.
Distilled Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the sodium bicarbonate, borax and phenol in 700 millilitres (14 fluid ounces) of distilled water, add the glycerin and sufficient distilled water to produce the required volume.

NEBULA BENZOINI COMPOSITA

(Neb. Benzoin. Co.)

Compound Benzoin Spray

			<i>Metric</i>	<i>Imperial</i>
Oil of Pumilio Pine	15 ml.	144 m.
Oil of Eucalyptus	30 ml.	288 m.
Oil of Cassia	15 ml.	144 m.
Menthol	10 g.	87½ gr.
Glycerin	500 ml.	10 fl. oz.
Tincture of Benzoin to 1000 ml.		to 20 fl. oz.

Dissolve the menthol and the oils in 400 millilitres (8 fluid ounces) of the tincture of benzoin, add the glycerin and sufficient tincture of benzoin to produce the required volume.

In making this preparation the tincture of benzoin may be replaced by tincture of benzoin prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

NEBULA COCAINÆ COMPOSITA

(Neb. Cocain. Co.)

Compound Cocaine Spray

			<i>Metric</i>	<i>Imperial</i>
Cocaine	5 g.	43½ gr.
Compound Menthol and Thymol				
Spray to 1000 ml.		to 20 fl. oz.
Dissolve.				

NEBULA EPHEDRINÆ COMPOSITA

(Neb. Ephed. Co.)

Compound Ephedrine Spray

			<i>Metric</i>	<i>Imperial</i>
Ephedrine	10 g.	87½ gr.
Menthol	20 g.	175 gr.
Camphor	20 g.	175 gr.
Oil of Thyme	20 ml.	192 m.
Light Liquid Paraffin to 1000 ml.		to 20 fl. oz.

Dissolve the ephedrine, menthol and camphor in the oil of thyme mixed with a portion of the light liquid paraffin, and dilute with sufficient light liquid paraffin to produce the required volume.

NEBULA EUCALYPTI

(Neb. Eucalyp.)

Eucalyptus Spray

		<i>Metric</i>	<i>Imperial</i>
Oil of Eucalyptus	50 ml.	1 fl. oz.
Light Liquid Paraffin to	1000 ml.	to 20 fl. oz.

Mix.

NEBULA EUCALYPTOLIS COMPOSITA

(Neb. Eucalyp. Co.)

Compound Eucalyptol Spray

Synonym—Nebula Thymolis Composita.

		<i>Metric</i>	<i>Imperial</i>
Eucalyptol	80 ml.	1 fl. oz. 288 m.
Camphor	20 g.	175 gr.
Menthol	20 g.	175 gr.
Thymol	1 g.	8½ gr.
Light Liquid Paraffin to	1000 ml.	to 20 fl. oz.

Dissolve the camphor, menthol and thymol in a portion of the light liquid paraffin, add the eucalyptol and sufficient light liquid paraffin to produce the required volume.

NEBULA GUAIACOLIS ET MENTHOLIS

(Neb. Guaiacol. et Menthol.)

Guaiacol and Menthol Spray

		<i>Metric</i>	<i>Imperial</i>
Guaiacol	20 ml.	192 m.
Menthol	40 g.	350 gr.
Light Liquid Paraffin to	1000 ml.	to 20 fl. oz.

Dissolve.

NEBULA HYOSCINÆ COMPOSITA

(Neb. Hyoscin. Co.)

Compound Hyoscine Spray

	<i>Metric</i>	<i>Imperial</i>
Hyoscine Hydrobromide ..	0.57 g.	.5 gr.
Cocaine Hydrochloride ..	9.13 g.	80 gr.
Atropine Sulphate ..	1.14 g.	10 gr.
Sodium Nitrite ..	125.0 g.	2½ oz.
Glycerin ..	250.0 ml.	5 fl. oz.
Solution of Bordeaux B ..	5.0 ml.	48 m.
Distilled Water to 1000.0 ml.	to 20 fl. oz.

Dissolve the solid ingredients in 600 millilitres (12 fluid ounces) of the distilled water; add the glycerin, the solution of bordeaux B and sufficient distilled water to produce the required volume.

NEBULA IODI COMPOSITA

(Neb. Iod. Co.)

Compound Iodine Spray

	<i>Metric</i>	<i>Imperial</i>
Iodine	10 g.	87½ gr.
Phenol	5 g.	43¾ gr.
Light Liquid Paraffin to 1000 ml.	to 20 fl. oz.

Dissolve the iodine in a portion of the light liquid paraffin with the aid of heat, add the phenol and sufficient light liquid paraffin to produce the required volume.

NEBULA IODI ET MENTHOLIS

(Neb. Iod. et Menthol.)

Iodine and Menthol Spray

	<i>Metric</i>	<i>Imperial</i>
Iodine	20 g.	175 gr.
Menthol	40 g.	350 gr.
Light Liquid Paraffin to 1000 ml.	to 20 fl. oz.

Dissolve the iodine in a portion of the light liquid paraffin with the aid of heat, add the menthol while the solution is warm, cool, and add sufficient light liquid paraffin to produce the required volume.

NEBULA MENTHOLIS ET THYMOLIS COMPOSITA

(Neb. Menthol. et Thymol. Co.)

Compound Menthol and Thymol Spray

	<i>Metric</i>	<i>Imperial</i>
Menthol	20 g.	175 gr.
Thymol	2 g.	17½ gr.
Camphor	20 g.	175 gr.
Phenol	20 g.	175 gr.
Light Liquid Paraffin	to 1000 ml.	to 20 fl. oz.

Dissolve.

OCULENTA**Ointments for the Eye**

Ointments for the eye are prepared with the sterilised basis, Oculentum Simplex, in accordance with the directions of the British Pharmacopœia, unless otherwise ordered. If the medicament is readily soluble in water it should be dissolved in the smallest quantity of sterilised water. This solution should then be incorporated gradually with the melted basis and the mixture triturated continuously until cold. If the medicament is not readily soluble in water it should be finely powdered, thoroughly levigated with a small quantity of the basis and finally incorporated with the remainder. The ointment should be packed in a sterilised container and stored in a cool place. Small collapsible tubes are the best type of container, since there is a much smaller risk of contamination than when a pot is used. When a medicament is in the form of an aqueous solution of an alkaloidal salt emulsified in the basis, the action is exerted much more rapidly and is more powerful than when it is in the form of an alkaloid in solution in the basis, because of the greater ease with which solution in the lachrymal secretion is effected.

OCULENTUM ACIDI BORICI

(Oculent. Acid. Boric.)

Boric Acid Eye Ointment

	<i>Metric</i>	<i>Imperial</i>
Boric Acid, in very fine powder ..	4 g.	20 gr.
Simple Eye Ointment	96 g.	480 gr.

Triturate the boric acid with a portion of the melted simple eye ointment until smooth and gradually add the remainder of the melted basis, triturating continuously until the product is cold.

OCULENTUM ATROPINÆ ET COCAINÆ**(Oculent. Atrop. et Cocain.)****Atropine and Cocaine Eye Ointment**

		<i>Metric</i>	<i>Imperial</i>
Atropine Sulphate	0.25 g.	1¼ gr.
Cocaine Hydrochloride	0.5 g.	2½ gr.
Sterilised Water	a sufficient quantity	
Simple Eye Ointment	to 100.0 g.	to 500 gr.

Dissolve the atropine sulphate and the cocaine hydrochloride in the minimum quantity of sterilised water, gradually add sufficient melted simple eye ointment, cooled to about 50°, to produce the required weight, and triturate continuously until cold.

OCULENTUM FLAVUM**(Oculent. Flav.)****Yellow Eye Ointment**

		<i>Metric</i>	<i>Imperial</i>
Moist Yellow Mercuric Oxide			
Ointment	10 g.	50 gr.
Simple Eye Ointment	90 g.	450 gr.

Mix.

OCULENTUM IODOFORMI ET ATROPINÆ**(Oculent. Iodof. et Atrop.)****Iodoform and Atropine Eye Ointment**

		<i>Metric</i>	<i>Imperial</i>
Iodoform, in fine powder	5.0 g.	25 gr.
Atropine Sulphate	0.125 g.	½ gr.
Sterilised Water	a sufficient quantity	
Simple Eye Ointment	to 100.0 g.	to 500 gr.

Dissolve the atropine sulphate in the minimum quantity of sterilised water, gradually add sufficient melted simple eye ointment, cooled to about 50°, to produce 95 grammes (475 grains) and triturate continuously until cold; then gradually incorporate the iodoform.

OCULENTUM SIMPLEX

(Oculent. Simp.)

Simple Eye Ointment

	<i>Metric</i>	<i>Imperial</i>
Wool Fat	10 g.	50 gr.
Yellow Soft Paraffin	90 g.	450 gr.

Melt together, filter while hot through coarse filter paper and sterilise by heating at 150° for one hour.

It should be **stored** in small, well-closed containers in a cool place.

OLEINATUM QUININÆ

(Oleinat. Quinin.)

Oleinate of Quinine

	<i>Metric</i>	<i>Imperial</i>
Quinine	250 g.	4 oz.
Oleic Acid to	1000 g.	to 16 oz.

Triturate the quinine in a warm mortar with a small quantity of the oleic acid until a smooth paste is formed; then add sufficient warmed oleic acid to produce the required weight, and stir until the quinine is dissolved.

OLEINATUM VERATRINÆ

(Oleinat. Veratrin.)

Oleinate of Veratrine

	<i>Metric</i>	<i>Imperial</i>
Veratrine	20 g.	140 gr.
Oleic Acid	500 g.	8 oz.
Olive Oil to	1000 g.	to 16 oz.

Triturate the veratrine with about 50 millilitres (385 minims) of olive oil, warm gently, add the oleic acid, stir until the veratrine is dissolved, and add sufficient olive oil to produce the required weight.

OLEORESINA CAPSICI

(Oleores. Capsic.)

Oleoresin of Capsicum

Synonyms—Capsicin; Extract of Capsicum.

	<i>Metric</i>	<i>Imperial</i>
Capsicum, in moderately coarse powder	1000 g.	16 oz.
Ether	a sufficient quantity	
Alcohol (90 per cent.)	a sufficient quantity	

Exhaust the capsicum by percolation in a continuous extractor with ether. Evaporate off the ether and extract the resulting product with successive quantities of alcohol (90 per cent.) until the insoluble residue is free from pungency. Mix the alcoholic solutions, recover most of the alcohol by distillation and remove the remainder by heating on a water-bath.

It is soluble in ether, benzene, chloroform, fixed oils and fats, and is approximately four times the strength of the oleoresin of the British Pharmaceutical Codex, 1923.

Dose.—0.0006 to 0.002 gramme ($\frac{1}{3000}$ to $\frac{1}{500}$ grain).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

OLEORESINA CUBEÆ

(Oleores. Cubeb.)

Oleoresin of Cubeb

	<i>Metric</i>	<i>Imperial</i>
Cubeb, in moderately coarse powder	1000 g.	16 oz.
Ether	a sufficient quantity	

Exhaust the cubeb by slow percolation with the ether until the percolate is colourless; recover the ether by distillation, allow the residue to stand in a closed vessel until waxy or crystalline matter ceases to be deposited, and decant the oleoresin.

It should be **stored** in well-stoppered bottles.

Dose.—0.3 to 2 millilitres (5 to 30 minims).

OLEORESINA ZINGIBERIS

(Oleores. Zingib.)

Oleoresin of Ginger

Synonym—Gingerin.

	<i>Metric</i>	<i>Imperial</i>
Ginger, in moderately fine powder	1000 g.	16 oz.
Acetone	a sufficient quantity	

Moisten the ginger with 50 millilitres (7 fluid drachms) of acetone, transfer as quickly as possible to a percolator with a closely fitting cover, pack tightly, and percolate slowly with acetone until exhaustion is complete; evaporate the percolate on a water-bath until it will barely pour.

It should be **stored** in well-stoppered bottles.

Dose.—0.016 to 0.06 gramme ($\frac{1}{4}$ to 1 grain).

OLEUM CARBOLISATUM

(Ol. Carbol.)

Carbolised Oil*Synonym*—Carbolic Oil.

				<i>Metric</i>	<i>Imperial</i>
Phenol	50 g.	1 oz.
Arachis Oil	to 1000 ml.	to 20 fl. oz.

Dissolve the phenol in about 900 millilitres (18 fluid ounces) of the arachis oil with the aid of gentle heat, cool, and add sufficient arachis oil to produce the required volume.

OLEUM LUBRICANS

(Ol. Lubric.)

Lubricant Oil*Synonyms*—Lund's Oil; Catheter Oil.

				<i>Metric</i>	<i>Imperial</i>
Phenol	50 g.	1 oz.
Castor Oil	200 ml.	4 fl. oz.
Arachis Oil	to 1000 ml.	to 20 fl. oz.

Dissolve the phenol in a mixture of the castor oil and about 700 millilitres (14 fluid ounces) of the arachis oil with the aid of gentle heat, cool, and add sufficient arachis oil to produce the required volume.

This preparation was prepared formerly with almond oil instead of arachis oil.

OLEUM PHOSPHORATUM

(Ol. Phosphor.)

Phosphorated Oil

				<i>Metric</i>	<i>Imperial</i>
Phosphorus	10 g.	70 gr.
Oil of Lemon	10 g.	70 gr.
Almond Oil	980 g.	15 oz. 297½ gr.

Heat the almond oil to 150°, cool, and filter into a stoppered bottle capable of holding rather more than the required quantity, add the phosphorus, warm to about 80°, shake until it is entirely dissolved, cool, and add the oil of lemon.

Dose.—0.06 to 0.3 millilitre (1 to 5 minims).

OLEUM RICINI AROMATICUM**(Ol. Ricin. Aromat.)****Aromatic Castor Oil**

	<i>Metric</i>	<i>Imperial</i>
Saccharin	0.4 g.	3½ gr.
Vanillin	1.1 g.	10 gr.
Chloroform	1.3 ml.	12½ m.
Oil of Cinnamon	2.6 ml.	25 m.
Oil of Pimento	2.6 ml.	25 m.
Oil of Clove	2.6 ml.	25 m.
Castor Oilto 1000.0 ml.	to 20 fl. oz.

Mix the chloroform with the oils of cinnamon, pimento and clove, add the saccharin and vanillin, dissolve with the aid of gentle heat and mix with the castor oil.

Dose.— 4 to 30 millilitres (1 to 8 fluid drachms).

PARENOL**(Paren.)****Parenol***Synonym*—Solid Parenol.

	<i>Metric</i>	<i>Imperial</i>
White Soft Paraffin or Yellow		
Soft Paraffin	650 g.	13 oz.
Wool Fat	150 g.	3 oz.
Distilled Water	200 g.	4 oz.

Melt the soft paraffin and wool fat, pour the mixture into a warm mortar and incorporate gradually the warmed distilled water.

PAROGENUM**(Parogen.)****Parogen***Synonyms*—Liquid Parogen; Vasoliment.

	<i>Metric</i>	<i>Imperial</i>
Liquid Paraffin	400 ml.	8 fl. oz.
Oleic Acid	400 ml.	8 fl. oz.
Ammoniated Alcohol	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	100 ml.	2 fl. oz.

Mix and agitate until a clear solution is obtained.

In making this preparation the ammoniated alcohol may be replaced by ammoniated alcohol prepared with industrial methylated spirit suitably diluted, and the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

PAROGENUM ICHTHAMMOLIS**(Parogen. Ichtham.)****Ichthammol Parogen**

Synonyms—Ichthammol Vasoliment; Ammonium Ichthosulphonate Parogen.

			<i>Metric</i>	<i>Imperial</i>
Ichthammol	100 g.	2 oz.
Parogen to 1000 ml.	to 20 fl. oz.

Mix, allow to stand for a short time, and strain.

PAROGENUM IODI**(Parogen. Iod.)****Iodine Parogen**

Synonyms—Iodine Vasoliment; Linimentum Iodi Petrolatum.

			<i>Metric</i>	<i>Imperial</i>
Iodine	100 g.	2 oz.
Oleic Acid	400 ml.	8 fl. oz.
Liquid Paraffin	400 ml.	8 fl. oz.
Ammoniated Alcohol	100 ml.	2 fl. oz.

Powder the iodine, triturate with the oleic acid until dissolved, and add the liquid paraffin and the ammoniated alcohol.

In making this preparation the ammoniated alcohol may be replaced by ammoniated alcohol prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

PAROGENUM SALICYLATUM**(Parogen. Salicylat.)****Salicylated Parogen**

Synonym—Salicylated Vasoliment.

			<i>Metric</i>	<i>Imperial</i>
Salicylic Acid	100 g.	2 oz.
Parogen to 1000 ml.	to 20 fl. oz.

Powder the salicylic acid, triturate it with about 900 millilitres (18 fluid ounces) of the parogen until dissolved, and add sufficient parogen to produce the required volume.

PASTÆ**Pastes**

Pastes are medicated preparations intended for external application. They are usually compounded with a basis of soft paraffin, liquid paraffin, starch and glycerin or water, bassorin paste, or gelatin and glycerin. They are employed principally as antiseptic, caustic, cooling, or soothing dressings in skin affections, and are usually applied with a brush or spread on lint, covered with a layer of absorbent cotton wool, and secured by a bandage or strapping plaster. Pastes prepared with a gelatin and glycerin basis are melted by standing the containers in hot water, and applied to the skin with a brush, the film produced being covered with lint or other suitable protective. Gelatin and glycerin pastes are usually medicated with substances possessing antiseptic or soothing properties, and the medicated films produced by their application are frequently employed for protection and relief in dermatology. Bassorin paste (*Linimentum Exsiccans*) consists of tragacanth, 5 parts; alcohol (90 per cent.), 10 parts; glycerin, 2 parts; distilled water, to 100 parts. This basis is sometimes used medicated with ichthammol (30 per cent.), boric acid (10 per cent.), chrysarobin (5 per cent.), betanaphthol (5 per cent.), resorcinol (30 per cent.), or salicylic acid (5 per cent.). When such preparations are smeared upon the skin and allowed to dry, a medicated film is produced, which can easily be removed by washing.

PASTA ACIDI STEARICI

(Past. Acid. Stear.)

Stearic Acid Paste*Synonym*—Unscented Vanishing Cream.

			<i>Metric</i>	<i>Imperial</i>
Stearic Acid	200 g.	4 oz.
Potassium Hydroxide	5 g.	43¾ gr.
Alcohol (90 per cent.)	50 ml.	1 fl. oz.
Borax	15 g.	131¼ gr.
Distilled Water	730 ml.	14 fl. oz. 288 m.

Melt the stearic acid on a water-bath, add the potassium hydroxide dissolved in the alcohol, then add, in one quantity, a boiling solution of the borax in the distilled water, stir thoroughly and allow to stand for twelve hours.

It should be **stored** in well-closed containers.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

PASTA ARSENICALIS

(Past. Arsen.)

Arsenical Paste

		<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	50 g.	2 oz.
Morphine Hydrochloride	25 g.	1 oz.
Creosote	a sufficient quantity	

Mix the arsenic trioxide and the morphine hydrochloride with sufficient creosote to form a stiff paste.

PASTA BISMUTHI

(Past. Bism.)

Bismuth Paste

		<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	300 g.	6 oz.
White Soft Paraffin	700 g.	14 oz.

Triturate the bismuth carbonate to a smooth paste in a sterilised mortar with the soft paraffin previously sterilised by heating for one hour at 150°, transfer to a flask, and plug the flask by placing a piece of gauze over the mouth and then forcing a pad of cotton wool into the neck; heat on a water-bath for thirty minutes; then cover the mouth of the flask with jaconet, securing the edges of the gauze and jaconet with a strip of plaster, and shake until the paste has set.

PASTA BISMUTHI ET IODOFORMI

(Past. Bism. et Iodof.)

Bismuth and Iodoform Paste*Synonym*—B.I.P.P.

		<i>Metric</i>	<i>Imperial</i>
Bismuth Subnitrate	250 g.	4 oz.
Iodoform	500 g.	8 oz.
Liquid Paraffin	250 g.	4 oz.

Mix.

PASTA HAMAMELIDIS

(Past. Hamam.)

Hamamelis Paste*Synonym*—Witch Hazel Cream.

	<i>Metric</i>	<i>Imperial</i>
Stearic Acid	100.0 g.	1 oz. 262½ gr.
Potassium Carbonate	7.5 g.	52½ gr.
Wool Fat	25.0 g.	175 gr.
Liquid Paraffin	15.0 ml.	115½ m.
Glycerin	50.0 g.	350 gr.
Solution of Hamamelis	500.0 ml.	8 fl. oz.
Distilled Water	300.0 ml.	4 fl. oz. 384 m

Dissolve the potassium carbonate in the distilled water heated nearly to boiling, gradually add the solution to the stearic acid, wool fat and liquid paraffin previously melted together with the aid of gentle heat, and mix. Add the glycerin mixed with the solution of hamamelis and heated to 90°, and stir vigorously until cold.

PASTA ICHTHAMMOLIS

(Past. Ichtham.)

Ichthammol Paste

Synonyms—Ammonium Ichthosulphonate Paste; Gelatinum Ichthammol; Ammonium Ichthosulphonate Jelly.

	<i>Metric</i>	<i>Imperial</i>
Ichthammol	100 g.	2 oz.
Gelatin	100 g.	2 oz.
Glycerin	600 g.	12 oz.
Distilled Water	250 ml.	5 fl. oz.

Soak the gelatin in the distilled water until softened and heat on a water-bath until dissolved, replace the water lost by evaporation, add the glycerin and ichthammol, and mix.

PASTA MAGNESII SULPHATIS

(Past. Mag. Sulph.)

Magnesium Sulphate Paste*Synonym*—Morison's Paste.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Magnesium Sulphate, dried at 100°	450 g.	7 oz. 87½ gr.
Glycerin	550 g.	8 oz. 350 gr.
Phenol	5 g.	35 gr.

Dissolve the phenol in the glycerin and mix with the exsiccated magnesium sulphate in a warm mortar.

It should be **stored** in well-closed jars or collapsible tubes.

PASTA PICIS CARBONIS

(*Past. Pic. Carbon.*)

Coal Tar Paste

	<i>Metric</i>	<i>Imperial</i>
Coal Tar	34.3 g.	240 gr.
Compound Paste of Zinc Oxide	to 1000.0 g.	to 16 oz.
Mix.		

PASTA RESORCINOLIS

(*Past. Resorcin.*)

Resorcinol Paste

Synonyms—Pasta Resorcini; Resorcin Paste; Lassar's Stronger Resorcin Paste.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	200 g.	4 oz.
Zinc Oxide, finely sifted ..	200 g.	4 oz.
Starch, finely sifted	200 g.	4 oz.
Liquid Paraffin	400 ml.	8 fl. oz.

Reduce the resorcinol to fine powder and mix with the zinc oxide, starch and liquid paraffin.

PASTA RESORCINOLIS MITIS

(*Past. Resorcin. Mit.*)

Mild Resorcinol Paste

Synonyms—Pasta Resorcini Mitis; Mild Resorcin Paste; Lassar's Mild Resorcin Paste.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	100 g.	1 oz.
Zinc Oxide, finely sifted ..	250 g.	2½ oz.
Starch, finely sifted	250 g.	2½ oz.
Liquid Paraffin	400 ml.	4 fl. oz.

Reduce the resorcinol to fine powder and mix with the zinc oxide, starch and liquid paraffin.

PASTA TRAGACANTHÆ COMPOSITA

(Past. Trag. Co.)

Compound Tragacanth Paste*Synonyms*—Pasta Lubricans; Catheter Lubricant.

	<i>Metric</i>	<i>Imperial</i>
Tragacanth, in powder	10 g.	87½ gr.
Boric Acid, in powder	30 g.	262½ gr.
Oil of Lavender	5 ml.	48 m.
Glycerin	100 ml.	2 fl. oz.
Decoction of Chondrus	to 1000 ml.	to 20 fl. oz.

Triturate the tragacanth and boric acid with the oil of lavender and glycerin and gradually add the decoction of chondrus. Sterilise by heating in an autoclave or by tyndallisation and transfer to sterile collapsible tubes.

PASTA ZINCI OXIDI CUM ACIDO SALICYLICO

(Past. Zinc. Oxid. c. Acid. Salicyl.)

Paste of Zinc Oxide with Salicylic Acid*Synonym*—Lassar's Paste.

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide, finely sifted	240 g.	6 oz.
Starch, finely sifted	240 g.	6 oz.
Salicylic Acid, finely sifted	20 g.	½ oz.
White Soft Paraffin	500 g.	12½ oz.

Mix.

PASTILLI**Pastilles**

Pastilles are soft masses of medicated glycogelatin used for applying medicaments to the throat and mouth. They may be prepared by pouring the liquefied medicated glycogelatin into starch moulds. The pastilles in the moulds are transferred to a warm atmosphere until dry, taken from the moulds, and any adherent starch removed by washing or by rolling the pastilles in a cloth. For small quantities of pastilles the glycogelatin may be melted on a water-bath and the active ingredient, in solution or suspension, incorporated. If insoluble, the medicament

should be triturated with a small portion of the melted glycogelatin or with a little glycerin before mixing with the remainder of the basis. The melted mixture is poured into circular moulds of suitable size or into a suitable tray to solidify and then cut into the required number of pastilles, each of which should measure about two centimetres in diameter and weigh about two grammes. The moulds may be lubricated with almond oil before pouring in the melted mixture. The quantities given in each formula are for one pastille. When the proportion of medicament to be contained in each pastille is not stated by the prescriber, the following quantity should be dispensed:—

Pastilli Ammonii Bromidi.—Ammonium bromide, 0·06 gramme (1 grain).

Pastilli Ammonii Chloridi.—Ammonium chloride, 0·13 gramme (2 grains).

Pastilli Benzinæ.—Benzamine hydrochloride, 0·03 gramme ($\frac{1}{2}$ grain).

Pastilli Cocainæ Hydrochloridi.—Cocaine hydrochloride, 0·0016 gramme ($\frac{1}{60}$ grain).

Pastilli Codeinæ.—Codeine, 0·008 gramme ($\frac{1}{8}$ grain).

Pastilli Diamorphinæ Hydrochloridi.—Diamorphine hydrochloride, 0·0016 gramme ($\frac{1}{60}$ grain).

Pastilli Eucalyptolis.—Eucalyptol, 0·03 millilitre ($\frac{1}{2}$ minim).

Pastilli Mentholis.—Menthol, 0·003 gramme ($\frac{1}{20}$ grain).

Pastilli Pyrethri.—Pyrethrum root, 0·06 gramme (1 grain).

PASTILLI AMMONII CHLORIDI COMPOSITI

(Pastill. Ammon. Chlorid. Co.)

Compound Ammonium Chloride Pastilles

	<i>Metric</i>	<i>Imperial</i>
Ammonium Chloride	0·13 g.	2 gr.
Liquid Extract of Liquorice ..	0·12 ml.	2 m.

PASTILLI DIAMORPHINÆ ET PINI COMPOSITI

(Pastill. Diamorph. et Pini Co.)

Compound Diamorphine and Pine Pastilles

	<i>Metric</i>	<i>Imperial</i>
Diamorphine Hydrochloride ..	0·0013 g.	$\frac{1}{40}$ gr.
Oil of Pumilio Pine	0·015 ml.	$\frac{1}{4}$ m.
Terpin Hydrate	0·008 g.	$\frac{1}{8}$ gr.

PASTILLI MENTHOLIS ET COCAINÆ

(Pastill. Menthol. et Cocain.)

Menthol and Cocaine Pastilles

	<i>Metric</i>	<i>Imperial</i>
Menthol	0·003 g.	$\frac{1}{80}$ gr.
Cocaine Hydrochloride	0·0016 g.	$\frac{1}{40}$ gr.

PASTILLI MENTHOLIS ET EUCALYPTOLIS

(Pastill. Menthol. et Eucalyp.)

Menthol and Eucalyptol Pastilles

	<i>Metric</i>	<i>Imperial</i>
Menthol	0·003 g.	$\frac{1}{80}$ gr.
Eucalyptol	0·03 ml.	$\frac{1}{2}$ m.

PESSI**Pessaries**

Pessaries are made by incorporating the requisite quantity of active ingredient, finely powdered if necessary, or dissolved in or mixed with a small quantity of distilled water, with melted oil of theobroma or glycerin suppository basis (Suppositorium Glycerini) and pouring the mixture into moulds capable of holding 8 grammes (120 grains), unless other sizes are ordered. When the proportion of medicament to be contained in each pessary is not stated by the prescriber, the following quantity should be dispensed, and unless otherwise directed, the basis used should be oil of theobroma.

Pessus Acidi Borici.—Boric acid, 0·6 gramme (10 grains).

Pessus Acidi Lactici.—Lactic acid, 0·15 millilitre ($2\frac{1}{2}$ minims), in 2 grammes (30 grains) of oil of theobroma.

Pessus Acidi Tannici.—Tannic acid, 0·6 gramme (10 grains).

Pessus Acriflavinae.—Acriflavine, 0·008 gramme ($\frac{1}{8}$ grain).

Pessus Aluminis.—Alum, 0·3 gramme (5 grains).

Pessus Ichthammolis.—Ichthammol, 0·6 gramme (10 grains), in glycerin suppository basis.

Pessus Quininæ Hydrochloridi.—Quinine hydrochloride, 0·2 gramme (3 grains), in 2 grammes (30 grains) of oil of theobroma.

Pessus Zinci Sulphatis.—Zinc sulphate, 0·3 gramme (5 grains).

PHENOL CUM CAMPHORA

(Phenol c. Camph.)

Phenol with Camphor*Synonyms*—Phenol Camphor; Carbolic Camphor.

				<i>Metric</i>	<i>Imperial</i>
Phenol	250 g.	5 oz.
Camphor	750 g.	15 oz.

Triturate together until liquefied.

PHENOL IODISATUM

(Phenol Iodisat.)

Iodised Phenol*Synonym*—Iodised Carbolic Acid.

				<i>Metric</i>	<i>Imperial</i>
Iodine	100 g.	2 oz.
Liquefied Phenol to 1000 ml.		to 20 fl. oz.

Dissolve.

PIGMENTA**Paints**

Paints are liquid preparations usually medicated with substances possessing antiseptic, caustic, soothing, or stimulating properties. They are prepared with vehicles which render their consistence suitable for application to the skin or mucous surfaces by means of a brush. The character of the bases differs considerably, the selection depending upon the nature of the medicament to be applied, the duration of contact desired, and the degree of absorption required. Caustic substances when employed as paints are usually applied dissolved in distilled water or occasionally in alcoholic or ethereal vehicles. Resinous substances, such as benzoin, storax, balsam of tolu, or sandarac, dissolved in ether, are employed as bases of medicated varnishes, and used for application to the skin and raw mucous surfaces. Bottles fitted with glass stoppers are usually most suitable as containers for paints. Paints containing chromium trioxide are applied by means of glass brushes.

PIGMENTUM ACONITI COMPOSITUM

(Fig. Aconit. Co.)

Compound Aconite Paint

				<i>Metric</i>	<i>Imperial</i>
Liniment of Aconite	375 ml.	7½ fl. oz.
Liniment of Belladonna	375 ml.	7½ fl. oz.
Chloroform	125 ml.	2½ fl. oz.
Distilled Water	125 ml.	2½ fl. oz.

Mix.

PIGMENTUM CHLORALIS ET CAMPHORÆ COMPOSITUM

(Fig. Chloral. et Camph. Co.)

Compound Chloral and Camphor Paint

	<i>Metric</i>	<i>Imperial</i>
Chloral Hydrate	250 g.	5 oz.
Camphor	250 g.	5 oz.
Phenol	250 g.	5 oz.

Triturate together until liquefied.

PIGMENTUM CHRYSAROBINI

(Fig. Chrysarob.)

Chrysarobin Paint

	<i>Metric</i>	<i>Imperial</i>
Chrysarobin	100 g.	2 oz.
Solution of Gutta Percha .. to 1000 ml.		to 20 fl. oz.

Dissolve.

PIGMENTUM HYDRARGYRI NITRATIS

(Fig. Hydrarg. Nit.)

Mercuric Nitrate Paint*Synonyms*—Guttæ Hydrargyri Nitratis; Mercuric Nitrate Drops.

	<i>Metric</i>	<i>Imperial</i>
Dilute Ointment of Mercuric Nitrate	62.5 g.	1½ oz.
Arachis Oil	to 1000.0 ml.	to 20 fl. oz.

Dissolve the ointment in a portion of the arachis oil with the aid of gentle heat, cool, and add sufficient arachis oil to produce the required volume.

PIGMENTUM HYDRARGYRI NITRATIS CUM MENTHOLE

(Fig. Hydrarg. Nit. c. Menthol.)

Mercuric Nitrate Paint with Menthol

	<i>Metric</i>	<i>Imperial</i>
Dilute Ointment of Mercuric Nitrate	62.5 g.	1½ oz.
Menthol	10.0 g.	87½ gr.
Arachis Oil	to 1000.0 ml.	to 20 fl. oz.

Dissolve the ointment and the menthol in a portion of the arachis oil with the aid of gentle heat, cool, and add sufficient arachis oil to produce the required volume.

PIGMENTUM IODI COMPOSITUM

(Fig. Iod. Co.)

Compound Iodine Paint*Synonym*—Mandl's Paint.

	<i>Metric</i>	<i>Imperial</i>
Iodine	12.5 g.	$\frac{1}{4}$ oz.
Potassium Iodide	25.0 g.	$\frac{1}{2}$ oz.
Distilled Water	25.0 ml.	$\frac{1}{2}$ fl. oz.
Oil of Peppermint	7.5 ml.	72 m.
Glycerin	to 1000.0 ml.	to 20 fl. oz.

Dissolve the iodine and potassium iodide in the distilled water, add a portion of the glycerin, the oil of peppermint, and then sufficient glycerin to produce the required volume.

The paint should be well shaken before use.

PIGMENTUM IODI ET ACONITI

(Fig. Iod. et Aconit.)

Iodine and Aconite Paint

	<i>Metric</i>	<i>Imperial</i>
Weak Solution of Iodine ..	500 ml.	10 fl. oz.
Strong Tincture of Aconite ..	500 ml.	10 fl. oz.

Mix.

In making this preparation the weak solution of iodine and the strong tincture of aconite may be replaced by a weak solution of iodine and a strong tincture of aconite prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

PIGMENTUM IODOFORMI COMPOSITUM

(Fig. Iodof. Co.)

Compound Iodoform Paint*Synonym*—Whitehead's Varnish.

	<i>Metric</i>	<i>Imperial</i>
Benzoin, coarsely powdered ..	100 g.	2 oz.
Storax	75 g.	1½ oz.
Balsam of Tolu	50 g.	1 oz.
Iodoform	100 g.	2 oz.
Ether	to 1000 ml.	to 20 fl. oz.

Macerate the benzoin, storax and balsam of tolu with 800 millilitres (16 fluid ounces) of the ether for seven days, frequently agitating; filter, dissolve the iodoform in the filtrate, and pass sufficient of the ether through the filter to produce the required volume.

PIGMENTUM MENTHOLIS ET TOLUENI**(Fig. Menthol. et Toluén.)****Menthol and Toluene Paint***Synonym*—Löffler's Paint.

	<i>Metric</i>	<i>Imperial</i>
Menthol	100 g.	2 oz.
Dehydrated Alcohol	600 ml.	12 fl. oz.
Strong Solution of Ferric Chloride	10 ml.	96 m.
Toluene to 1000 ml.		to 20 fl. oz.

Dissolve the menthol in 300 millilitres (6 fluid ounces) of the toluene mixed with the dehydrated alcohol, add the strong solution of ferric chloride and sufficient toluene to produce the required volume.

PIGMENTUM OLEI PICIS CUM IODO**(Fig. Ol. Pic. c. Iod.)****Oil of Tar and Iodine Paint**

Synonyms—Pigmentum Picis cum Iodo; Pasta Iodi et Picis; Coster's Paste.

	<i>Metric</i>	<i>Imperial</i>
Iodine	200 g.	4 oz.
Rectified Oil of Tar	800 ml.	16 fl. oz.

Dissolve with the aid of gentle heat, applied cautiously.

PIGMENTUM SALOLIS**(Fig. Salol.)****Salol Paint**

	<i>Metric</i>	<i>Imperial</i>
Salol	33.3 g.	291½ gr.
Glycerin	200.0 ml.	4 fl. oz.
Alcohol (90 per cent.) to 1000.0 ml.		to 20 fl. oz.
Dissolve.		

PILULÆ**Pills**

Pills are prepared from masses of a special consistence made by incorporating medicaments with suitable inert substances, termed excipients. In preparing the pill mass, the medicaments must be

uniformly distributed throughout the mass, potent substances being carefully diluted with the larger quantities of less potent ingredients before massing with the excipient. Small quantities of potent substances may be obtained by making a triturate with lactose as described under *Pulveres*. The mass should be thoroughly plastic, and sufficiently firm to retain a spherical shape when made into pills. The diameter of pills should rarely be less than $\frac{1}{8}$ inch (about 1 grain in weight) or more than $\frac{1}{4}$ inch (about 5 grains in weight). When the ingredients are liable to change on exposure to air, or are of a volatile, bitter, or nauseous character, the pills should be coated. The coating may consist of varnish, gelatin, sugar, silver leaf, or a pearl coating. When medicaments are required to act in the intestines and not in the stomach, an enteric coating is usually applied.

Excipients.—Excipients vary considerably in their physical characters. They are usually either more or less viscous liquids, powdered gums, absorbent, fibrous, vegetable powders, powdered soap, or chemically inert substances such as kaolin. The choice of the excipient is very important, for the latter should not exert a medicinal action of its own or affect that of the medicaments, neither should it render the mass insoluble, for it is important that the pills should dissolve or disintegrate readily on being swallowed. Any excipient which prevents this must be carefully avoided. When the ingredients of the pills are colourless it is desirable to avoid introducing a coloured excipient; lactose may be employed when a diluent is required, and syrup of liquid glucose as excipient. The following excipients are in general use:—

Syrup of Liquid Glucose forms a very satisfactory general excipient for massing ingredients which contain fibrous matter or, in conjunction with a little powdered gum, for substances which contain no binding material. A mass made with this excipient usually disintegrates readily.

Liquid Glucose may replace syrup of liquid glucose with advantage when greater cohesiveness is wanted. Its viscosity makes it a difficult excipient to manipulate.

Glycerin of Tragacanth requires to be very sparingly used since excess may produce an elastic mass which is difficult to convert into spherical pills.

Powdered Gum, in the form of acacia or tragacanth, or a mixture of equal parts of each, known as compound powder of acacia (*Pulvis Acaciæ Compositus*), is a valuable addition when there is no binding material in the ingredients. Not more than about 5 per cent. should be added, the pills being massed with syrup of liquid glucose. When too much tragacanth is used an elastic mass may be formed.

Liquorice, in powder, possesses excellent absorbent properties. By virtue of its fibrous nature it is an ideal combination with syrup of liquid glucose for producing a mass. It is also useful for stiffening masses containing soft extracts.

Powdered Soap can be used with advantage to absorb volatile oils, or substances of a similar nature, the mass being subsequently stiffened with powdered liquorice. One minim of oil usually requires 1 grain of powdered curd soap and about $1\frac{1}{2}$ grains of powdered liquorice to stiffen it.

Kaolin, or Diatomite, with wool fat is a useful excipient for substances such as potassium permanganate, potassium dichromate, silver nitrate, etc., which cannot be massed with the usual excipients, but require chemically inert diluents. The medicament should be made into a paste with the minimum quantity of wool fat and then stiffened by the addition of kaolin or diatomite.

The following **scheme for the preparation of pill masses** is of almost general application.

(a) When binding material, such as gum, fibre, or soft or dry aqueous extracts, is present, the ingredients should be massed with syrup of liquid glucose.

(b) When no binding material is present, as in the case of camphor, sulphur, thymol, resins, reduced iron and crystalline substances such as ferrous sulphate, 5 per cent. of compound powder of acacia should be added, and the ingredients massed with syrup of liquid glucose. In certain cases it is advisable to substitute liquid glucose for the syrup, to give greater cohesiveness.

(c) Volatile oils and similar substances should be absorbed in powdered curd soap, and the mass stiffened with powdered liquorice.

(d) Oxidising substances, such as potassium permanganate, should be made into a paste with the minimum amount of wool fat, and the mass stiffened with kaolin or diatomite.

Coatings.—The rapidity with which pills produce effect depends more upon the character of their mass than upon that of the coating with which they are enveloped. The selection of a suitable excipient is of primary importance. It has been shown by experiment that the presence of the coatings in general use does not retard the disintegration of pills to any appreciable extent. If a coating does not dissolve in contact with moisture and warmth, rupture readily ensues through the expansion of the pill, providing the consistence of the latter is plastic and not unduly hard. The practice in vogue in most pharmacies of invariably coating pills, unless otherwise ordered, is advantageous from every point of view. Coated pills are tasteless and elegant in appearance, they are less liable to deteriorate on keeping, and are usually more acceptable to the patient than uncoated pills.

Varnish Coating is in general use, and a solution of sandarac in alcohol (95 per cent.) (1 in 2) or equal volumes of alcohol (95 per cent.) and ether is commonly employed. About 5 to 8 drops of the solution suffice to coat one dozen 5 grain pills. The pills should be shaken from the varnishing pot on to a slab previously smeared with a small quantity of oil, and allowed to dry.

Silver Leaf provides an elegant coating for pills, which should be firm in consistence and have a well-polished surface free from powder. About two leaves should be sufficient for twelve 5 grain pills. The pills are first made tacky with dilute mucilage of acacia, and then rotated in the silver leaf in a warm, dry, porcelain pot. Silver coating should not be used for pills containing substances liable to affect it, such as sulphides, unless they are previously varnished.

Sugar Coating can only be applied satisfactorily to large quantities of pills by machinery adapted for the purpose. When a sweetened pill coating is required at the dispensing counter, it is customary to use purified talc containing 2 per cent. of soluble saccharin or a small percentage of sugar.

Gelatin Coating, particularly if applied by machinery, provides elegant and satisfactory results. For coating on a small scale, the pills may be impaled on needles and then dipped in thin, melted gelatin solution. They should then be set aside to dry in such a manner that excess of the gelatin solution can drain down the needles. A suitable gelatin solution may be prepared from the following formula:—gelatin, 1 part, mucilage of acacia, 1 part, saturated solution of boric acid, to 10 parts.

Pearl Coating, unlike sugar coating, can be carried out at the dispensing counter. It consists in building up successive layers of purified talc on the pills with the aid of mucilage. The pills should preferably be fairly hard. Elegant results depend to some extent upon practice, and more especially upon the application of a suitable amount of adhesive solution to the pill previous to coating. The following method has proved satisfactory in practice:—Varnish the pills with a sandarac varnish, and transfer while still wet to a covered pot containing a small quantity of purified talc which may be sweetened with soluble saccharin. Rotate five or six times, and transfer the pills to a pill rounder; remove any superfluous talc by rotating and rubbing the pills on the rounder with demy paper; place a few drops (about 4 drops for each dozen 5 grain pills) of pill-coating mucilage (mucilage of acacia, 1 part, syrup, 1 part, distilled water, 4 parts) in a dry, covered pot; add the pills; rotate a few times, and transfer to another pot (concave within) containing a small quantity of purified talc; rotate gently and not too rapidly for about ten to fifteen seconds; transfer to an inverted lid, and rotate gently for a minute; set aside to dry for at least fifteen minutes, and finish by rotating the pills in a dry pot (concave within) until they have a uniform and polished appearance. The process, excluding the quarter of an hour during which the pills are set aside, usually occupies less than ten minutes if the requisite materials are ready to hand.

Enteric Coatings are employed for covering pills which are intended to pass through the stomach and act in the intestines. When the medicament is such that it may be inactivated in the stomach, or depends for its efficient action on being released in the intestines in a

concentrated form, the efficiency of the coating is of great importance. The efficiency may be tested by immersing the pills in a dilute solution of hydrochloric acid and pepsin at 37° for two hours with occasional shaking, and then under similar conditions in an alkaline pancreatin solution. The pills should not disintegrate in the former, but should do so in the latter solution. The efficiency of the coating may be destroyed if it should crack owing to the expansion of the pill mass at body temperature. Salol coatings are very liable to do this. Enteric coatings in general use are:—

Formaldehyde-Gelatin or Glutoid Coating. The pills are gelatin coated, allowed to dry, then immersed in a solution of formaldehyde (2 per cent. H·CHO) for fifteen minutes, and dried. This coating is usually satisfactory and rarely cracks.

Stearic Acid. This may be applied by rotating the pills in a little melted stearic acid in a round-bottomed flask for a few seconds, and then jerking the pills out on a large sheet of paper so that they roll sufficiently far for the coating to set. The pills may then be returned to the flask, and the operation quickly repeated. In this manner any desired thickness of coating may be applied. The stearic acid in the flask should be kept just above its melting-point except for the first coating, when it is an advantage to have it at a somewhat higher temperature and therefore much thinner. When the pill mass is of a non-greasy character, it is advisable to moisten the pills with a solution of white wax in ether, allowing the latter to evaporate. Unless this is done, the coating tends to crack readily and peel off.

Salol Coating. This may be applied in the same manner as stearic acid. Non-greasy pill masses should be similarly waxed before coating, otherwise the salol will not adhere.

Keratin Coating. The pills are moistened by rotation in a pot with a 10 per cent. solution of keratin in equal parts of alcohol and strong solution of ammonia, and then shaken out on to an oiled tile to dry. The operation is generally repeated several times, and three or four coatings applied. When the pill mass is of a non-greasy character it should be waxed as in stearic acid coating.

PILULÆ ALOES ET MYRRHÆ

(Pil. Aloes et Myrrh.)

Aloes and Myrrh Pills

Synonyms—Pilulæ Rufi; Rufus Pills.

	<i>Metric</i>	<i>Imperial</i>
Aloes, in fine powder	1.56 g.	24 gr.
Myrrh	0.78 g.	12 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.—1 or 2 pills.

PILULÆ ALOES ET NUCIS VOMICÆ

(Pil. Aloes et Nuc. Vom.)

Aloes and Nux Vomica Pills

	<i>Metric</i>	<i>Imperial</i>
Aloes, in fine powder	1.56 g.	24 gr.
Dry Extract of Nux Vomica ..	0.19 g.	3 gr.
Dry Extract of Belladonna ..	0.13 g.	2 gr.
Alcohol (60 per cent.)	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.**PILULÆ ALOINI COMPOSITÆ**

(Pil. Aloin. Co.)

Compound Aloin Pills*Synonym*—Andrew Clark's Liver Pills.

	<i>Metric</i>	<i>Imperial</i>
Aloin	0.39 g.	6 gr.
Dry Extract of Nux Vomica ..	0.39 g.	6 gr.
Exsiccated Ferrous Sulphate ..	0.39 g.	6 gr.
Myrrh	0.39 g.	6 gr.
Hard Soap, in fine powder ..	0.39 g.	6 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.**PILULÆ ALOINI ET PODOPHYLLINI COMPOSITÆ**

(Pil. Aloin. et Podoph. Co.)

Compound Aloin and Podophyllin Pills

	<i>Metric</i>	<i>Imperial</i>
Aloin	0.32 g.	5 gr.
Oleoresin of Capsicum	0.03 g.	$\frac{1}{2}$ gr.
Jalap Resin	0.32 g.	5 gr.
Resin of Podophyllum	0.49 g.	$7\frac{1}{2}$ gr.
Dry Extract of Nux Vomica ..	0.16 g.	$2\frac{1}{2}$ gr.
Dry Extract of Hyoscyamus ..	0.16 g.	$2\frac{1}{2}$ gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 50 pills.

Dose.— 1 to 4 pills.

PILULÆ ALOINI ET STRYCHNINÆ COMPOSITÆ

(Pil. Aloin. et Strych. Co.)

Compound Aloin and Strychnine Pills

	<i>Metric</i>	<i>Imperial</i>
Aloin	0.65 g.	10 gr.
Strychnine	0.065 g.	1 gr.
Dry Extract of Belladonna	0.32 g.	5 gr.
Powdered Ipecacuanha	0.16 g.	2½ gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 50 pills.

Dose.— 1 or 2 pills.**PILULÆ ASAFÆTIDÆ**

(Pil. Asafœt.)

Asafetida Pills

	<i>Metric</i>	<i>Imperial</i>
Asafetida	2.33 g.	36 gr.
Hard Soap, in fine powder	0.58 g.	9 gr.
Distilled Water	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ ASIATICÆ**

(Pil. Asiatic.)

Asiatic Pills

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	0.065 g.	1 gr.
Black Pepper, in fine powder	0.58 g.	9 gr.
Extract of Gentian	0.13 g.	2 gr.

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.**PILULÆ CASCARÆ COMPOSITÆ**

(Pil. Casc. Co.)

Compound Cascara Pills*Synonym*—Pilulæ Cascaræ, Belladonnæ et Nucis Vomicaæ.

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Cascara Sagrada	2.59 g.	40 gr.
Dry Extract of Nux Vomica	0.32 g.	5 gr.
Dry Extract of Belladonna	0.32 g.	5 gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 50 pills.

Dose.— 1 to 3 pills.

PILULÆ COLCHICI ET ALOES

(Pil. Colch. et Aloes)

Colchicum and Aloes Pills

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Colchicum ..	0·19 g.	3 gr.
Aloes, in fine powder ..	0·19 g.	3 gr.
Dry Extract of Hyoscyamus ..	0·19 g.	3 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 to 4 pills.**PILULÆ COLCHICI ET HYDRARGYRI**

(Pil. Colch. et Hydrarg.)

Colchicum and Mercury Pills

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Colchicum ..	0·13 g.	2 gr.
Pill of Mercury	0·26 g.	4 gr.
Compound Extract of Colocynth	0·39 g.	6 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 to 3 pills.**PILULÆ COLCHICI ET HYDRARGYRI COMPOSITÆ**

(Pil. Colch. et Hydrarg. Co.)

Compound Colchicum and Mercury Pills*Synonym*—Brodie's Gout Pills.

	<i>Metric</i>	<i>Imperial</i>
Dry Extract of Colchicum ..	0·39 g.	6 gr.
Pill of Mercury	1·04 g.	16 gr.
Compound Extract of Colocynth	1·04 g.	16 gr.
Extract of Rhubarb	1·04 g.	16 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ COLOCYNTHIDIS COMPOSITÆ

(Pil. Colocynth. Co.)

Compound Pills of Colocynth*Synonym*—Pil. Cochia.

	<i>Metric</i>	<i>Imperial</i>
Colocynth, in fine powder ..	0.52 g.	8 gr.
Aloes, in fine powder	1.04 g.	16 gr.
Scammony Resin, in fine powder	1.04 g.	16 gr.
Curd Soap, in fine powder ..	0.26 g.	4 gr.
Oil of Clove	0.15 ml.	2½ m.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ COLOCYNTHIDIS ET HYDRARGYRI**

(Pil. Colocynth. et Hydrarg.)

Colocynth and Mercury Pills*Synonym*—Abernethy's Pills.

	<i>Metric</i>	<i>Imperial</i>
Compound Extract of Colocynth	1.56 g.	24 gr.
Pill of Mercury	2.33 g.	36 gr.

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ COLOCYNTHIDIS ET HYDRARGYRI
COMPOSITÆ**

(Pil. Colocynth. et Hydrarg. Co.)

Compound Colocynth and Mercury Pills

	<i>Metric</i>	<i>Imperial</i>
Pill of Colocynth and Hyoscyamus	0.58 g.	9 gr.
Pill of Mercury	0.19 g.	3 gr.

Mix to form a mass and divide into 12 pills.

Dose.— 1 to 4 pills.

PILULÆ DAMIANÆ COMPOSITÆ

(Pil. Damian. Co.)

Compound Damiana Pills

	<i>Metric</i>	<i>Imperial</i>
Extract of Damiana	6.48 g.	100 gr.
Dry Extract of Nux Vomica ..	0.32 g.	5 gr.
Phosphorated Suet	0.32 g.	5 gr.
Chloroform	0.59 ml.	10 m.
Compound Powder of Tragacanth	0.32 g.	5 gr.
Mucilage of Acacia	a sufficient quantity	

Mix quickly the phosphorated suet, extract of damiana, dry extract of nux vomica and chloroform, then add the compound powder of tragacanth and sufficient mucilage of acacia to form a mass. Divide into 50 pills and varnish.

Dose.— 1 pill.

PILULÆ DIGITALIS COMPOSITÆ

(Pil. Digit. Co.)

Compound Digitalis Pills

Synonyms—Pilulæ Digitalis cum Scilla; Guy's Pills; Niemeyer's Pills.

	<i>Metric</i>	<i>Imperial</i>
Powdered Digitalis	0.78 g.	12 gr.
Squill, in powder	0.78 g.	12 gr.
Pill of Mercury	0.78 g.	12 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ FERRI CARBONATIS COMPOSITÆ

(Pil. Ferr. Carb. Co.)

Compound Iron Carbonate Pills

Synonym—Blaud's Pill with Aloin and Cascara.

	<i>Metric</i>	<i>Imperial</i>
Aloin	0.16 g.	2½ gr.
Dry Extract of Cascara Sagrada	0.81 g.	12½ gr.
Exsiccated Sodium Carbonate ..	1.75 g.	27 gr.
Exsiccated Ferrous Sulphate ..	2.75 g.	42½ gr.
Tragacanth, in powder	0.16 g.	2½ gr.
Acacia, in powder	0.68 g.	10½ gr.
Liquid Glucose	2.59 g.	40 gr.
Distilled Water	0.45 ml.	7½ m.

Mix the aloin, dry extract of cascara sagrada and exsiccated sodium carbonate, add to the previously mixed liquid glucose, distilled water and exsiccated ferrous sulphate, and set aside for ten minutes or until the reaction is complete; add the tragacanth and acacia, mix to form a mass and divide into 25 pills.

Dose.— 1 to 3 pills.

PILULÆ FERRI CARBONATIS CUM ARSENO ET STRYCHNINA

(Pil. Ferr. Carb. c. Arsen. et Strych.)

Pills of Iron Carbonate with Arsenic and Strychnine

Synonym—Blaud's Pills with Arsenic and Strychnine.

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	0·065 g.	1 gr.
Strychnine Hydrochloride ..	0·065 g.	1 gr.
Exsiccated Sodium Carbonate ..	7·00 g.	108 gr.
Exsiccated Ferrous Sulphate ..	11·02 g.	170 gr.
Tragacanth, in powder	0·65 g.	10 gr.
Acacia, in powder	2·72 g.	42 gr.
Liquid Glucose	10·37 g.	160 gr.
Distilled Water	0·59 ml.	10 m.

Triturate the arsenic trioxide and strychnine hydrochloride with a small quantity of the exsiccated sodium carbonate, and gradually add the remainder, triturating thoroughly; add the resulting powder to the previously mixed liquid glucose, distilled water and exsiccated ferrous sulphate, and set aside for ten minutes or until the reaction is complete; add the tragacanth and acacia, mix to form a mass and divide into 100 pills.

Dose.— 1 or 2 pills.

PILULÆ FERRI CARBONATIS ET ARSENI

(Pil. Ferr. Carb. et Arsen.)

Pills of Iron Carbonate and Arsenic

Synonym—Blaud's Pills with Arsenic.

	<i>Metric</i>	<i>Imperial</i>
Arsenic Trioxide	0·065 g.	1 gr.
Exsiccated Sodium Carbonate ..	3·50 g.	54 gr.
Exsiccated Ferrous Sulphate ..	5·51 g.	85 gr.
Tragacanth, in powder	0·32 g.	5 gr.
Acacia, in powder	1·36 g.	21 gr.
Liquid Glucose	5·18 g.	80 gr.
Distilled Water	0·30 ml.	5 m.

Triturate the arsenic trioxide with a small quantity of the exsiccated sodium carbonate and gradually add the remainder, triturating thoroughly; add the resulting powder to the previously mixed liquid glucose, distilled water and exsiccated ferrous sulphate, and set aside for ten minutes or until the reaction is complete; add the tragacanth and acacia, mix to form a mass and divide into 50 pills.

Dose.— 1 pill.

PILULÆ FERRI CARBONATIS SACCHARATI

(Pil. Ferr. Carb. Sacch.)

Saccharated Ferrous Carbonate Pills

	<i>Metric</i>	<i>Imperial</i>
Saccharated Ferrous Carbonate	2.33 g.	36 gr.
Liquorice, in fine powder	0.58 g.	9 gr.
Liquid Glucose	0.78 g.	12 gr.
Distilled Water	0.18 ml.	3 m.

Mix to form a mass and divide into 12 pills.

Dose.— 1 to 3 pills.

PILULÆ FERRI ET ARSENI

(Pil. Ferr. et Arsen.)

Iron and Arsenic Pills

Synonym—Pilulæ Ferri Arsenicales.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Ferrous Sulphate ..	2.33 g.	36 gr.
Arsenic Trioxide	0.013 g.	$\frac{1}{8}$ gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ FERRI PHOSPHATIS CUM QUININA ET STRYCHNINA

(Pil. Ferr. Phosph. c. Quinin. et Strych.)

Iron Phosphate Pills with Quinine and Strychnine

Synonyms—Pilulæ Trium Phosphatum; Easton's Pills; Pilulæ Ferri et Quininæ et Strychninæ Phosphatum.

	<i>Metric</i>	<i>Imperial</i>
Saccharated Iron Phosphate ..	0.91 g.	14 gr.
Quinine Sulphate	0.32 g.	5 gr.
Strychnine Hydrochloride ..	0.0065 g.	$\frac{1}{10}$ gr.
Lactose	a sufficient quantity	
Phosphoric Acid	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ FERRI VALERIANATIS COMPOSITÆ

(Pil. Ferr. Valer. Co.)

Compound Iron Valerianate Pills*Synonym*—Pilulæ Trium Valerianatum.

		<i>Metric</i>	<i>Imperial</i>
Iron Valerianate	0·78 g.	12 gr.
Quinine Valerianate	0·78 g.	12 gr.
Zinc Valerianate	0·78 g.	12 gr.
Compound Powder of Acacia	0·13 g.	2 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ GALBANI COMPOSITÆ**

(Pil. Galban. Co.)

Compound Pills of Galbanum*Synonym*—Compound Pills of Asafetida.

		<i>Metric</i>	<i>Imperial</i>
Asafetida	0·78 g.	12 gr.
Galbanum	0·78 g.	12 gr.
Myrrh	0·78 g.	12 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix in a warm mortar to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ HYDRARGYRI CUM CRETA ET OPII**

(Pil. Hydrarg. c. Cret. et Opii)

Mercury with Chalk and Opium Pills*Synonym*—Hutchinson's Pills.

		<i>Metric</i>	<i>Imperial</i>
Mercury with Chalk	0·78 g.	12 gr.
Powder of Ipecacuanha and Opium	0·78 g.	12 gr.
Compound Powder of Acacia	0·06 g.	1 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.

PILULÆ HYDRARGYRI CUM RHEO

(Pil. Hydrarg. c. Rheo)

Mercury Pills with Rhubarb

	<i>Metric</i>	<i>Imperial</i>
Pill of Mercury	1.94 g.	30 gr.
Compound Pill of Rhubarb ..	1.94 g.	30 gr.

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.**PILULÆ HYDRARGYRI SUBCHLORIDI, COLOCYNTHIDIS
ET HYOSCYAMI**

(Pil. Hydrarg. Subchlor. Colocynth. et Hyoscy.)

Mercurous Chloride, Colocynth and Hyoscyamus Pills*Synonyms*—Calomel, Colocynth and Hyoscyamus Pills; Zittmann's Pills.

	<i>Metric</i>	<i>Imperial</i>
Mercurous Chloride	0.78 g.	12 gr.
Compound Extract of Colocynth ..	1.94 g.	30 gr.
Dry Extract of Hyoscyamus ..	0.78 g.	12 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ HYDRARGYRI SUBCHLORIDI COMPOSITÆ**

(Pil. Hydrarg. Subchlor. Co.)

Compound Mercurous Chloride Pills*Synonyms*—Compound Calomel Pills; Plummer's Pills.

	<i>Metric</i>	<i>Imperial</i>
Mercurous Chloride	0.78 g.	12 gr.
Sulphurated Antimony	0.78 g.	12 gr.
Guaiacum Resin	1.56 g.	24 gr.
Acacia, in powder	0.039 g.	$\frac{3}{5}$ gr.
Tragacanth, in powder	0.039 g.	$\frac{3}{5}$ gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ HYDRARGYRI SUBCHLORIDI ET COLOCYNTHIDIS

(Pil. Hydrarg. Subchlor. et Colocynth.)

Mercurous Chloride and Colocynth Pills

Synonym—Calomel and Colocynth Pills.

	<i>Metric</i>	<i>Imperial</i>
Mercurous Chloride	0·78 g.	12 gr.
Compound Extract of Colocynth	3·12 g.	48 gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.

PILULÆ IPECACUANHÆ CUM SCILLA

(Pil. Ipecac. c. Scill.)

Ipecacuanha Pills with Squill

	<i>Metric</i>	<i>Imperial</i>
Powder of Ipecacuanha and Opium	1·56 g.	24 gr.
Squill, in powder	0·52 g.	8 gr.
Ammoniacum	0·52 g.	8 gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ OVOLECITHINI

(Pil. Ovolecithin.)

Ovolecithin Pills

Synonyms—Pilulæ Lecithini; Lecithin Pills.

	<i>Metric</i>	<i>Imperial</i>
Ovolecithin	1·17 g.	18 gr.
Strychnine Hydrochloride	0·013 g.	$\frac{1}{8}$ gr.
Althæa, in powder	0·78 g.	12 gr.
Liquorice, in fine powder	0·78 g.	12 gr.
Acacia, in powder	0·39 g.	6 gr.
Alcohol (90 per cent.)	a sufficient quantity	
Glycerin	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 to 4 pills.

PILULÆ PHENOLPHTHALEINI COMPOSITÆ

(Pil. Phenolphthal. Co.)

Compound Phenolphthalein Pills*Synonym*—Pilulæ Phenaloini.

	<i>Metric</i>	<i>Imperial</i>
Aloin	0.19 g.	3 gr.
Phenolphthalein .. .	0.39 g.	6 gr.
Strychnine .. .	0.0097 g.	$\frac{3}{320}$ gr.
Dry Extract of Belladonna .	0.06 g.	1 gr.
Powdered Ipecacuanha ..	0.05 g.	$\frac{1}{8}$ gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.**PILULÆ PHOSPHORI**

(Pil. Phosphor.)

Phosphorus Pills

	<i>Metric</i>	<i>Imperial</i>
Phosphorus .. .	0.032 g.	$\frac{1}{2}$ gr.
Oil of Theobroma .	1.28 g.	20 gr.
Wool Fat .. .	0.352 g.	5 $\frac{1}{2}$ gr.
Kaolin .. .	0.512 g.	8 gr.
Exsiccated Sodium Sulphate .	1.024 g.	16 gr.
Carbon Disulphide .. .	0.64 ml.	11 m.

Dissolve the phosphorus and 0.64 gramme (10 grains) of the oil of theobroma in the carbon disulphide. Allow the solution to evaporate in a mortar until a pasty mass is obtained. To this add the remainder of the oil of theobroma together with the other ingredients, mix to form a mass and divide into 50 pills.

The pills should be freshly prepared.

Dose.— 1 to 4 pills.**PILULÆ PLUMBI CUM OPIO**

(Pil. Plumb. c. Opio)

Lead Pills with Opium

	<i>Metric</i>	<i>Imperial</i>
Lead Acetate, in powder ..	2.60 g.	40 gr.
Powdered Opium .. .	0.39 g.	6 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	

Mix to form a mass and divide into 25 pills.

Dose.— 1 or 2 pills.

PILULÆ PODOPHYLLINI, BELLADONNÆ ET NUCIS VOMICÆ

(Pil. Podoph. Bellad. et Nuc. Vom.)

Podophyllin, Belladonna and Nux Vomica Pills

	<i>Metric</i>	<i>Imperial</i>
Resin of Podophyllum	0·26 g.	4 gr.
Dry Extract of Belladonna	0·26 g.	4 gr.
Dry Extract of Nux Vomica	0·26 g.	4 gr.
Aloes, in fine powder	0·78 g.	12 gr.
Distilled Water	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ PODOPHYLLINI COMPOSITÆ

(Pil. Podoph. Co.)

Compound Podophyllin Pills

	<i>Metric</i>	<i>Imperial</i>
Resin of Podophyllum	0·19 g.	3 gr.
Mercurous Chloride	0·78 g.	12 gr.
Dry Extract of Belladonna	0·13 g.	2 gr.
Tragacanth, in powder	0·13 g.	2 gr.
Lactose, in powder	0·39 g.	6 gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.

PILULÆ PODOPHYLLINI ET QUININÆ

(Pil. Podoph. et Quinin.)

Podophyllin and Quinine Pills

Synonym—Poore's Pills.

	<i>Metric</i>	<i>Imperial</i>
Resin of Podophyllum	0·06 g.	1 gr.
Quinine Sulphate	0·78 g.	12 gr.
Dry Extract of Belladonna	0·10 g.	1½ gr.
Aloes, in fine powder	0·78 g.	12 gr.
Syrup of Liquid Glucose	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 pill.

PILULÆ QUININÆ SULPHATIS

(Pil. Quinin. Sulph.)

Quinine Sulphate Pills*Synonyms*—Pilulæ Quininæ; Quinine Pills.

		<i>Metric</i>	<i>Imperial</i>
Quinine Sulphate	3.24 g.	50 gr.
Acacia, in powder	0.32 g.	5 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 25 pills.

Dose.— 1 to 4 pills.**PILULÆ SAPONIS CUM OPIO**

(Pil. Sap. c. Opio)

Soap Pills with Opium*Synonyms*—Pilulæ Saponis Compositæ; Compound Soap Pills.

		<i>Metric</i>	<i>Imperial</i>
Powdered Opium	0.65 g.	10 gr.
Hard Soap, in powde.	1.95 g.	30 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 25 pills.

Dose.— 1 or 2 pills.**PILULÆ SCAMMONIÆ COMPOSITÆ**

(Pil. Scammon. Co.)

Compound Scammony Pills

		<i>Metric</i>	<i>Imperial</i>
Scammony Resin, in fine powder		0.78 g.	12 gr.
Jalap Resin, in fine powder	..	0.78 g.	12 gr.
Curd Soap, in fine powder	..	0.78 g.	12 gr.
Ginger, in fine powder	..	0.26 g.	4 gr.
Alcohol (60 per cent.)	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.— 1 or 2 pills.

PILULÆ SCILLÆ COMPOSITÆ

(Pil. Scill. Co.)

Compound Squill Pills

		<i>Metric</i>	<i>Imperial</i>
Squill, in powder	0.78 g.	12 gr.
Ginger, in fine powder	0.624 g.	9 ² / ₃ gr.
Ammoniacum	0.624 g.	9 ² / ₃ gr.
Hard Soap, in powder	0.468 g.	7 ¹ / ₅ gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose—1 or 2 pills.

PILULÆ ZINCI OXIDI ET BELLADONNÆ

(Pil. Zinc. Oxid. et Bellad.)

Zinc Oxide and Belladonna Pills

		<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	1.56 g.	24 gr.
Dry Extract of Belladonna	..	0.19 g.	3 gr.
Lactose	0.39 g.	6 gr.
Syrup of Liquid Glucose	..	a sufficient quantity	

Mix to form a mass and divide into 12 pills.

Dose.—1 pill.

POTUS IMPERIALIS

(Potus Imperial.)

Imperial Drink

Synonym—Haustus Imperialis.

		<i>Metric</i>	<i>Imperial</i>
Potassium Acid Tartrate	..	4.6 g.	40 gr.
Citric Acid	0.8 g.	7 gr.
Sucrose	50.0 g.	1 oz.
Oil of Lemon	..	0.3 ml.	3 m.
Tincture of Lemon	..	5.2 ml.	50 m.
Distilled Waterto 1000.0 ml.		to 20 fl. oz.

Dissolve the potassium acid tartrate, citric acid and sucrose in 900 millilitres (18 fluid ounces) of boiling distilled water; allow to cool, add the oil of lemon previously dissolved in the tincture of lemon, and then sufficient distilled water to produce the required volume.

PULVERES**Powders**

Powders are usually mixtures of two or more powdered substances and may be for either internal or external use. They may be prepared by mixing the ingredient, or ingredients, ordered in smallest quantity with gradually increasing quantities of the remaining material. For dispensing purposes this is commonly accomplished by light trituration in a mortar, but small quantities may be mixed more conveniently on paper by means of a spatula. Powders intended for direct application externally, and also many powders for internal use, particularly those containing coloured ingredients, should, after mixing, be passed through a sieve of suitable mesh, usually a No. 60; they should then again be triturated lightly, since partial separation of the constituents may have occurred. On a large scale, mixing machines may be used. Before mixing, all solid ingredients should be finely powdered, and in some cases it is customary to employ the powdered drugs in general use without reference to a particular degree of comminution.

When the quantity of an ingredient required is less than 1 grain, or is such that it cannot conveniently be weighed on ordinary dispensing scales, a suitable trituration is prepared by admixture with lactose, and a proportionately larger quantity of the trituration is weighed. If, for example, $\frac{3}{8}$ grain of atropine sulphate is required for the total number of powders ordered, 1 grain of the sulphate is triturated with 24 grains of lactose, and of this mixture 3 grains ($\frac{3}{8}$ grain of atropine sulphate) is used. When a small quantity of a potent ingredient is ordered by itself in a powder, the weight of each powder should be increased to 2 grains by the addition of lactose. If any of the constituents are deliquescent or volatile, the powder should be doubly wrapped, the inner wrapper consisting of waxed or parchment paper; in extreme cases the wrapped powder may finally be enclosed in tin-foil.

The degree of comminution of vegetable drugs used in the manufacture of pharmaceutical preparations is expressed in the following terms:—

A **coarse** powder is one of which all the particles pass through a No. 10 sieve, and not more than 40 per cent. through a No. 44 sieve.

A **moderately coarse** powder is one of which all the particles pass through a No. 22 sieve, and not more than 40 per cent. through a No. 60 sieve.

A **moderately fine** powder is one of which all the particles pass through a No. 44 sieve, and not more than 40 per cent. through a No. 85 sieve.

A **fine** powder is one of which all the particles pass through a No. 85 sieve.

A **very fine** powder is one of which all the particles pass through a silk sieve containing in each direction, parallel to the threads, not less than 120 meshes per inch.

PULVIS ACETANILIDI COMPOSITUS

(Pulv. Acetanilid. Co.)

Compound Acetanilide Powder

		<i>Metric</i>	<i>Imperial</i>
Acetanilide, in powder	700 g.	11 oz. 87½ gr.
Caffeine, in powder	100 g.	1 oz. 262½ gr.
Sodium Bicarbonate	200 g.	3 oz. 87½ gr.

Mix.

Dose.—0·2 to 0·3 gramme (3 to 5 grains).**PULVIS ACIDI BORICI ET AMYLI**

(Pulv. Acid. Boric. et Amyli)

Boric Acid and Starch Powder

		<i>Metric</i>	<i>Imperial</i>
Boric Acid, in powder	500 g.	8 oz.
Starch, in powder	500 g.	8 oz.

Sift and mix.

PULVIS ACIDI SALICYLICI COMPOSITUS

(Pulv. Acid. Salicyl. Co.)

Compound Salicylic Acid Powder*Synonym*—Pulvis pro Pedibus.

		<i>Metric</i>	<i>Imperial</i>
Salicylic Acid, in powder	30 g.	210 gr.
Boric Acid, in powder	100 g.	1 oz. 262½ gr.
Purified Talc, in powder	870 g.	13 oz. 402½ gr.

Sift and mix.

PULVIS ALOES ET CANELLÆ

(Pulv. Aloes et Canell.)

Aloes and Canella Powder*Synonym*—Hiera Picra.

		<i>Metric</i>	<i>Imperial</i>
Aloes, finely powdered	800 g.	12 oz. 350 gr.
Canella, finely powdered	200 g.	3 oz. 87½ gr.

Mix.

Dose.—0·2 to 0·6 gramme (3 to 10 grains).

PULVIS AMYGDALÆ COMPOSITUS

(Pulv. Amygdal. Co.)

Compound Powder of Almond

		<i>Metric</i>	<i>Imperial</i>
Sweet Almond	600 g.	9 oz. 262½ gr.	
Sucrose, in powder	300 g.	4 oz. 350 gr.	
Acacia, in powder	100 g.	1 oz. 262½ gr.	

Blanch, dry and reduce the almond to a coarse powder; mix the acacia with the sucrose, add to the powdered almond, and mix.

PULVIS ANTIMONIALIS

(Pulv. Antim.)

Antimonial Powder

		<i>Metric</i>	<i>Imperial</i>
Antimonious Oxide	250 g.	5 oz.	
Calcium Phosphate	500 g.	10 oz.	

Mix.

Dose.—0·2 to 0·4 gramme (3 to 6 grains).

PULVIS BARI SULPHATIS COMPOSITUS

(Pulv. Bari Sulphatis Co.)

Compound Powder of Barium Sulphate*Synonyms*—Barium Meal; Shadow Meal.

		<i>Metric</i>	<i>Imperial</i>
Barium Sulphate	750 g.	12 oz.	
Cocoa Powder	94 g.	1½ oz.	
Arrowroot	94 g.	1½ oz.	
Compound Powder of Tragacanth	31 g.	½ oz.	
Sucrose, in powder	31 g.	½ oz.	

Mix.

Dose.—120 to 240 grammes (4 to 8 ounces), mixed immediately before use with a sufficient quantity of boiling water poured directly on to the powder.

PULVIS BISMUTHI COMPOSITUS

(Pulv. Bism. Co.)

Compound Bismuth Powder

			<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	100 g.	2 oz.
Calcium Carbonate	300 g.	6 oz.
Heavy Magnesium Carbonate	300 g.	6 oz.
Sodium Bicarbonate	100 g.	2 oz.

Mix.

Dose.— 1 to 4 grammes ($\frac{1}{4}$ to 1 drachm).**PULVIS BORACIS COMPOSITUS**

(Pulv. Borac. Co.)

Compound Borax Powder*Synonyms*—Pulvis Alkalinus Compositus; Compound Alkaline Powder.

			<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	300 g.	4 oz.
Sodium Chloride, in powder	300 g.	4 oz.
Borax, in powder	300 g.	4 oz.

Mix.

Use.— For a nasal wash, 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm) is dissolved in half a pint of warm water.**PULVIS CATECHU COMPOSITUS**

(Pulv. Catech. Co.)

Compound Powder of Catechu

			<i>Metric</i>	<i>Imperial</i>
Catechu, finely powdered	400 g.	6 oz. 175 gr.
Kino, finely powdered	200 g.	3 oz. 87½ gr.
Krameria, finely powdered	200 g.	3 oz. 87½ gr.
Cinnamon, finely powdered	100 g.	1 oz. 262½ gr.
Nutmeg, finely powdered	100 g.	1 oz. 262½ gr.

Mix.

Dose.— 0·6 to 4 grammes (10 to 60 grains).

PULVIS CINNAMOMI COMPOSITUS

(Pulv. Cinnam. Co.)

Compound Cinnamon Powder*Synonym*—Pulvis Aromaticus.

	<i>Metric</i>	<i>Imperial</i>
Cinnamon, finely powdered ..	250 g.	4 oz.
Cardamom, finely powdered ..	250 g.	4 oz.
Ginger, finely powdered ..	250 g.	4 oz.

Mix.

Dose.—0·6 to 4 grammes (10 to 60 grains).**PULVIS EFFERVESCENS COMPOSITUS DUPLEX**

(Pulv. Efferv. Co. Dup.)

Double Compound Effervescent Powder*Synonym*—Double-strength Seidlitz Powder.

No. 1.	<i>Metric</i>	<i>Imperial</i>
Sodium Potassium Tartrate, in dry powder	15·0 g.	231½ gr.
Sodium Bicarbonate, in dry powder	2·5 g.	38½ gr.

Mix, and wrap in blue paper.

No. 2.	<i>Metric</i>	<i>Imperial</i>
Tartaric Acid, in dry powder ..	2·5 g.	38½ gr.

Wrap in white paper.

Dose.—Dissolve No. 1 powder in a tumbler of cold or warm water; then add No. 2 powder. The liquid should be taken while effervescing.**PULVIS EFFERVESCENS COMPOSITUS FORTIS**

(Pulv. Efferv. Co. Fort.)

Strong Compound Effervescent Powder*Synonym*—Extra-strong Seidlitz Powder.

No. 1.	<i>Metric</i>	<i>Imperial</i>
Sodium Potassium Tartrate, in dry powder	11·25 g.	173½ gr.
Sodium Bicarbonate, in dry powder	2·5 g.	38½ gr.

Mix and wrap in blue paper.

No. 2.	<i>Metric</i>	<i>Imperial</i>
Tartaric Acid, in dry powder ..	2·5 g.	38½ gr.

Wrap in white paper.

Dose.—Dissolve No. 1 powder in a tumbler of cold or warm water; then add No. 2 powder. The liquid should be taken while effervescing.

PULVIS IODOFORMI ET ACIDI BORICI

(Pulv. Iodof. et Acid. Boric.)

Iodoform and Boric Acid Powder

	<i>Metric</i>	<i>Imperial</i>
Iodoform, in powder	250 g.	4 oz.
Boric Acid, in powder	750 g.	12 oz.
Mix.		

PULVIS KINO COMPOSITUS

(Pulv. Kino Co.)

Compound Powder of Kino

	<i>Metric</i>	<i>Imperial</i>
Kino, finely powdered	750 g.	12 oz.
Powdered Opium, in fine powder	50 g.	350 gr.
Cinnamon, finely powdered ..	200 g.	3 oz. 87½ gr.
Mix.		

Dose.— 0·3 to 1·2 grammes (5 to 20 grains).**PULVIS LOBELIÆ COMPOSITUS**

(Pulv. Lobel. Co.)

Compound Lobelia Powder

	<i>Metric</i>	<i>Imperial</i>
Lobelia, in moderately coarse powder	250 g.	4 oz.
Stramonium, in moderately coarse powder	250 g.	4 oz.
Tea, in moderately coarse powder	250 g.	4 oz.
Potassium Nitrate	250 g.	4 oz.
Oil of Anise	1 ml.	8 m.
Distilled Water, boiling	250 ml.	4 fl. oz.

Dissolve the potassium nitrate in the water, add the solution to the mixed powders, mix thoroughly, dry, and add the oil of anise.

PULVIS MAGNESII BOROCITRATIS COMPOSITUS

(Pulv. Mag. Borocit. Co.)

Compound Magnesium Borocitrate Powder

	<i>Metric</i>	<i>Imperial</i>
Magnesium Borocitrate	300 g.	5 oz.
Sucrose, in powder	600 g.	10 oz.

Mix.

Dose.— 2 to 4 grammes (½ to 1 drachm).

PULVIS OPII COMPOSITUS

(Pulv. Opii Co.)

Compound Powder of Opium

	<i>Metric</i>	<i>Imperial</i>
Powdered Opium, in fine powder	100 g.	1 oz. 262½ gr.
Black Pepper, finely powdered ..	150 g.	2 oz. 175 gr.
Ginger, finely powdered ..	300 g.	4 oz. 350 gr.
Caraway, finely powdered ..	420 g.	6 oz. 315 gr.
Tragacanth, in powder	30 g.	210 gr.

Mix.

Dose.—0.3 to 1 gramme (5 to 15 grains).**PULVIS PANCREATINI COMPOSITUS**

(Pulv. Pancreatin. Co.)

Compound Pancreatin Powder*Synonyms*—Peptonising Powder; Pulvis Pancreaticus Compositus.

	<i>Metric</i>	<i>Imperial</i>
Pancreatin	200 g.	3 oz. 87½ gr.
Sodium Bicarbonate	800 g.	12 oz. 350 gr.

Mix.

PULVIS PEPSINI COMPOSITUS

(Pulv. Pepsin. Co.)

Compound Pepsin Powder

	<i>Metric</i>	<i>Imperial</i>
Pepsin, finely powdered	150.0 g.	2 oz. 175 gr.
Pancreatin, finely powdered ..	100.0 g.	1 oz. 262½ gr.
Diastase, finely powdered ..	10.0 g.	70 gr.
Lactic Acid	12.5 ml.	96 m.
Hydrochloric Acid	12.5 ml.	96 m.
Lactose, finely powdered	to 1000.0 g.	to 16 oz.

Add the lactic acid and hydrochloric acid gradually to 625 grammes (10 ounces) of the lactose, and triturate until thoroughly mixed; add the pepsin, pancreatin and diastase, previously mixed, and sufficient lactose to produce the required weight; pass the mixture through a fine sieve.

It should be **stored** in well-closed bottles.**Dose.**—0.6 to 2 grammes (10 to 30 grains).

PULVIS SCAMMONIÆ COMPOSITUS

(Pulv. Scammon. Co.)

Compound Powder of Scammony

	<i>Metric</i>	<i>Imperial</i>
Scammony Resin, finely powdered	500 g.	8 oz.
Jalap, finely powdered	350 g.	5 oz. 262½ gr.
Ginger, finely powdered	150 g.	2 oz. 175 gr.

Mix.

Dose.—0·6 to 1·2 grammes (10 to 20 grains).**PULVIS SODII CHLORIDI COMPOSITUS**

(Pulv. Sod. Chlorid. Co.)

Compound Powder of Sodium Chloride

	<i>Metric</i>	<i>Imperial</i>
Sodium Chloride, in powder ..	250 g.	4 oz.
Sodium Bicarbonate	250 g.	4 oz.
Borax, in powder	250 g.	4 oz.
Sucrose, in powder	250 g.	4 oz.

Mix.

PULVIS STRAMONII COMPOSITUS

(Pulv. Stramon. Co.)

Compound Stramonium Powder

	<i>Metric</i>	<i>Imperial</i>
Stramonium, in moderately coarse powder	500 g.	8 oz.
Lobelia, in moderately coarse powder	60 g.	420 gr.
Anise, in moderately coarse powder	120 g.	1 oz. 402½ gr.
Tea, in moderately coarse powder	60 g.	420 gr.
Potassium Nitrate	250 g.	4 oz.
Oil of Eucalyptus	10 ml.	75 m.
Distilled Water, boiling	250 ml.	4 fl. oz.

Dissolve the potassium nitrate in the water, add the solution to the mixed powders, mix thoroughly, dry, and add the oil of eucalyptus.

PULVIS TALCI BORICUS

(Pulv. Talc. Boric.)

Boric Talc Powder*Synonym*—Talcum Boratum.

		<i>Metric</i>	<i>Imperial</i>
Boric Acid, in powder	100 g.	1 oz. 262½ gr.
Starch, in powder	100 g.	1 oz. 262½ gr.
Oil of Geranium	2 ml.	15 m.
Purified Talc to 1000 g.	to 16 oz.

Incorporate the oil of geranium with the powders, sift and mix.

PULVIS ZINCI ET ACIDI BORICI

(Pulv. Zinc. et Acid. Boric.)

Zinc and Boric Acid Powder

		<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	500 g.	8 oz.
Boric Acid, in powder	500 g.	8 oz.

Sift and mix.

PULVIS ZINCI ET ACIDI SALICYLICI

(Pulv. Zinc. et Acid. Salicyl.)

Zinc and Salicylic Acid Powder

		<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	200 g.	3 oz. 87½ gr.
Salicylic Acid, in powder	50 g.	350 gr.
Starch, in powder	750 g.	12 oz.

Sift and mix.

PULVIS ZINCI ET AMYLI

(Pulv. Zinc. et Amyli)

Zinc and Starch Powder

		<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	500 g.	8 oz.
Starch, in powder	500 g.	8 oz.

Sift and mix.

PULVIS ZINCI ET AMYLI COMPOSITUS

(Pulv. Zinc. et Amyli Co.)

Compound Zinc and Starch Powder

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	250 g.	4 oz.
Starch, in powder	250 g.	4 oz.
Boric Acid, in powder	250 g.	4 oz.
Oil of Geranium	2 ml.	15 m.
Purified Talc	to 1000 g.	to 16 oz.

Incorporate the oil of geranium with the powders, sift and mix.

PULVIS ZINCI OLEOSTEARATIS COMPOSITUS

(Pulv. Zinc. Oleostear. Co.)

Compound Zinc Oleostearate Powder

	<i>Metric</i>	<i>Imperial</i>
Zinc Oleostearate, in powder ..	250 g.	4 oz.
Boric Acid, in powder .. .	250 g.	4 oz.
Oil of Geranium	2 ml.	15 m.
Starch, in powder	to 1000 g.	to 16 oz.

Incorporate the oil of geranium with the powders, sift and mix.

PULVIS ZINCI SULPHATIS COMPOSITUS

(Pulv. Zinc. Sulph. Co.)

Compound Zinc Sulphate Powder

Synonyms—Pulvis Acidi Borici Compositus; Compound Boric Acid Powder; Pulvis Antisepticus Solubilis; Soluble Antiseptic Powder.

	<i>Metric</i>	<i>Imperial</i>
Zinc Sulphate	125 g.	2 oz.
Eucalyptol	1 g.	7 gr.
Menthol	1 g.	7 gr.
Phenol	1 g.	7 gr.
Salicylic Acid	5 g.	35 gr.
Thymol	1 g.	7 gr.
Boric Acid, in powder	866 g.	13 oz. 374½ gr.

Triturate together the menthol, phenol and thymol, add the eucalyptol, and then the salicylic acid and zinc sulphate, previously finely powdered; then gradually add the boric acid in small portions, mixing thoroughly.

RESINA CARBOLISATA

(Res. Carbol.)

Carbolised Resin

	<i>Metric</i>	<i>Imperial</i>
Phenol	20 g.	1 oz.
Mastic, in powder	20 g.	1 oz.
Colophony, in powder	40 g.	2 oz.
Chloroform	20 ml.	1 fl. oz.

Shake together in a stoppered bottle until dissolved.

SAL APERIENS SULPHURATUM

(Sal Aper. Sulphurat.)

Sulphurated Aperient Salt*Synonym*—Harrogate Salts.

	<i>Metric</i>	<i>Imperial</i>
Potassium Acid Tartrate	150 g.	2 oz. 175 gr.
Sulphurated Potash	30 g.	210 gr.
Exsiccated Magnesium Sulphate	820 g.	13 oz. 52½ gr.

Reduce to fine powder and mix.

Dose.—4 to 8 grammes (1 to 2 drachms).

SAL CAROLINUM FACTITIUM

(Sal Carol. Fact.)

Artificial Carlsbad Salt

	<i>Metric</i>	<i>Imperial</i>
Sodium Sulphate	550 g.	8 oz. 350 gr.
Potassium Sulphate	10 g.	70 gr.
Sodium Chloride	100 g.	1 oz. 262½ gr.
Sodium Carbonate	350 g.	5 oz. 262½ gr.
Distilled Water	550 ml.	8 fl. oz. 384 m.

Dissolve the potassium sulphate and sodium chloride in the water, and add the solution to the sodium carbonate and sodium sulphate, previously melted in a tared dish; evaporate until the weight of the product is 1000 grammes (16 ounces) and set aside to cool, stirring frequently so as to avoid the formation of large crystals. Distribute any remaining mother liquor uniformly over the crystals, and dry by exposure to the air.

Dose.—2 to 6 grammes (½ to 1½ drachms).

SAL CAROLINUM FACTITIUM EFFERVESCENS

(Sal Carol. Fact. Efferv.)

Effervescent Artificial Carlsbad Salt*Synonym*—Effervescent Carlsbad Powder.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Sodium Sulphate ..	90.0 g.	1 oz. 192½ gr.
Sodium Potassium Tartrate ..	380.0 g.	6 oz. 35 gr.
Sodium Chloride.. ..	30.0 g.	210 gr.
Sodium Bicarbonate	330.0 g.	5 oz. 122½ gr.
Saccharin	0.5 g.	3½ gr.
Tartaric Acid	169.5 g.	2 oz. 311½ gr.

Dry the ingredients separately, powder and mix.

Dose.—4 to 8 grammes (1 to 2 drachms).**SEVUM BENZOINATUM**

(Sev. Benz.)

Benzoinated Suet

	<i>Metric</i>	<i>Imperial</i>
Suet	1000 g.	16 oz.
Benzoin, coarsely powdered ..	30 g.	210 gr.

Melt the suet, add the benzoin, and maintain at a temperature of 60° for one hour, stirring frequently; strain, and stir constantly until cold.

SEVUM PHOSPHORATUM

(Sev. Phosphor.)

Phosphorated Suet

	<i>Metric</i>	<i>Imperial</i>
Phosphorus	100 g.	1 oz. 262½ gr.
Suet	900 g.	14 oz. 175 gr.

Dissolve the phosphorus in 500 millilitres (8 fluid ounces) of carbon disulphide, add a little of the suet and mix quickly, then add the remainder of the suet, mix thoroughly, and allow the carbon disulphide to evaporate.

Dose.—0.006 to 0.03 gramme ($\frac{1}{160}$ to $\frac{1}{2}$ grain).**SOLVELLÆ****Solution-Tablets**

Solution-tablets are compressed tablets intended to be dissolved in water for external or local use. In the preparation of these tablets it is necessary that all the ingredients, including the lubricant and any diluent, should be readily soluble in water. The lubricant generally used is boric acid, and sodium chloride is often employed as a diluent.

Solution-tablets may be prepared in the manner described for ordinary tablets, but when they contain poisonous ingredients, a suitable dye is often added to distinguish them. When the proportion of medicament to be contained in each solution-tablet is not stated by the prescriber, the following quantity should be dispensed:—

Solvellæ Acidi Borici.—Boric acid, 1 gramme (15 grains).

Solvellæ Aluminis.—Alum, 0·6 gramme (10 grains).

Solvellæ Potassii Permanganatis.—Potassium permanganate, 0·3 gramme (5 grains).

Solvellæ Sodii Chloridi.—Sodium chloride, 1·3 gramme (20 grains).

SOLVELLÆ ACIDI TANNICI COMPOSITÆ

(Solv. Acid. Tann. Co.)

Compound Tannic Acid Solution-Tablets

	<i>Metric</i>	<i>Imperial</i>
Tannic Acid, in powder ..	56·70 g.	2 oz.
Mercuric Chloride, in powder ..	1·62 g.	25 gr.
Boric Acid, in powder ..	19·44 g.	300 gr.
Lactose, in powder ..	12·96 g.	200 gr.

Carefully mix the mercuric chloride with the tannic acid, and granulate with the aid of a sufficient quantity [about 10·6 millilitres (180 minims)] of syrup or of mucilage of acacia, add the boric acid and lactose, mix and compress lightly into 100 tablets.

SOLVELLÆ ANTISEPTICÆ

(Solv. Antisep.)

Antiseptic Solution-Tablets

Synonym—Effervescing Mouth-Wash Tablets.

	<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	32·40 g.	1 oz. 62½ gr.
Borax, in powder	19·44 g.	300 gr.
Sodium Benzoate, in powder ..	3·24 g.	50 gr.
Boric Acid, in powder	3·24 g.	50 gr.
Menthol, in powder	0·08 g.	1¼ gr.
Thymol, in powder	0·08 g.	1¼ gr.
Oil of Eucalyptus	0·30 ml.	5 m.
Oil of Lemon	0·30 ml.	5 m.
Tartaric Acid, in powder ..	25·92 g.	400 gr.
Saccharin	0·06 g.	1 gr.
Lactose, in powder	19·44 g.	300 gr.
Eosin	0·10 g.	1½ gr.
Solution of Carmine	7·10 ml.	2 fl. dr.
Distilled Water	7·10 ml.	2 fl. dr.

Dissolve the eosin in the distilled water and mix with the solution of carmine. Dry the tartaric acid and the lactose separately, by the application of heat; mix the dried powders, granulate with a sufficient quantity of the solution of eosin and carmine, and dry the granules. Mix the saccharin, sodium bicarbonate, borax and sodium benzoate with the remainder of the solution of eosin and carmine; granulate, dry the granules and mix them with the previously granulated tartaric acid and lactose. Mix the menthol, thymol, oil of eucalyptus and oil of lemon with the boric acid, mix with the granules and compress into 100 tablets.

They should be **stored** in dry, well-closed containers.

SOLVELLÆ BORACIS COMPOSITÆ

(Solv. Borac. Co.)

Compound Solution-Tablets of Borax

	<i>Metric</i>	<i>Imperial</i>
Borax	32.40 g.	1 oz. 62½ gr.
Sodium Chloride.. .. .	16.20 g.	250 gr.
Thymol	0.32 g.	5 gr.
Sodium Bicarbonate	16.20 g.	250 gr.

Mix, and make into 100 tablets.

SOLVELLÆ BORACIS ET BENZAMINÆ COMPOSITÆ

(Solv. Borac. et Benzamin. Co.)

Compound Solution-Tablets of Borax and Benzamine

Synonym—Naso-Pharyngeal Solution-Tablets.

	<i>Metric</i>	<i>Imperial</i>
Sodium Chloride.. .. .	32.40 g.	1 oz. 62½ gr.
Borax	19.44 g.	300 gr.
Boric Acid	6.48 g.	100 gr.
Sodium Benzoate	3.24 g.	50 gr.
Menthol	0.06 g.	1 gr.
Thymol	0.06 g.	1 gr.
Benzamine Hydrochloride ..	1.62 g.	25 gr.
Oil of Sweet Birch	0.30 ml.	5 m.

Mix, and make into 100 tablets.

One solution-tablet should be dissolved in 60 to 90 millilitres (2 to 3 fluid ounces) of warm water.

SOLVELLÆ BORACIS ET COCAINÆ COMPOSITÆ

(Solv. Borac. et Cocain. Co.)

Compound Solution-Tablets of Borax and Cocaine

	<i>Metric</i>	<i>Imperial</i>
Sodium Chloride.. ..	32.40 g.	1 oz. 62½ gr.
Borax	19.44 g.	300 gr.
Boric Acid	6.48 g.	100 gr.
Sodium Benzoate	3.24 g.	50 gr.
Menthol	0.06 g.	1 gr.
Thymol	0.06 g.	1 gr.
Cocaine Hydrochloride	0.54 g.	8½ gr.
Oil of Sweet Birch	0.30 ml.	5 m.

Mix, and make into 100 tablets.

One solution-tablet should be dissolved in 60 to 90 millilitres (2 to 3 fluid ounces) of warm water.

SOLVELLÆ HYDRARGYRI IODIDI

(Solv. Hydrarg. Iod.)

Mercuric Iodide Solution-Tablets*Synonym*—Soluble Biniodide Tablets.

	<i>Metric</i>	<i>Imperial</i>
Mercuric Iodide	56.76 g.	2 oz.
Potassium Iodide	45.36 g.	1 oz. 262½ gr.
Eosin	0.13 g.	2 gr.

Mix, and make into 100 tablets.

One solution-tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 1000 of mercuric iodide.

SOLVELLÆ HYDRARGYRI OXYCYANIDI

(Solv. Hydrarg. Oxycyanid.)

Mercuric Oxycyanide Solution-Tablets

	<i>Metric</i>	<i>Imperial</i>
Mercuric Oxycyanide	28.35 g.	1 oz.
Eosin	0.03 g.	½ gr.

Mix, and make into 100 tablets.

One solution-tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 2000 of mercuric oxycyanide.

SOLVELLÆ HYDRARGYRI PERCHLORIDI**(Solv. Hydrarg. Perchlor.)****Mercuric Chloride Solution-Tablets**

Synonyms—Antiseptic Perchloride Tablets; Antiseptic Corrosive Sublimate Tablets.

			<i>Metric</i>	<i>Imperial</i>
Mercuric Chloride	56.70 g.	2 oz.
Sodium Chloride..	56.70 g.	2 oz.
Methylene Blue	0.39 g.	6 gr.

Mix, and make into 100 tablets.

One solution-tablet dissolved in 20 fluid ounces of water forms a solution containing 1 in 1000 of mercuric chloride.

SPIRITUS ÆTHERIS COMPOSITUS**(Sp. Æther. Co.)****Compound Spirit of Ether**

Synonym—Hoffmann's Anodyne.

			<i>Metric</i>	<i>Imperial</i>
Ether	137.5 ml.	2 $\frac{3}{4}$ fl. oz.
Alcohol (90 per cent.)	1950.0 ml.	39 fl. oz.
Sulphuric Acid	900.0 ml.	18 fl. oz.
Distilled Water	37.5 ml.	$\frac{3}{4}$ fl. oz.
Sodium Bicarbonate	a sufficient quantity	

Gradually mix the sulphuric acid with 1000 millilitres (20 fluid ounces) of the alcohol, allow the mixture to stand for twenty-four hours, and then distil slowly until the temperature of the liquid rises to 171.6°. Pour the distillate into a separator and reject the lower layer. Add the distilled water to the upper layer and gradually add sodium bicarbonate until, after thorough agitation, the mixture is nearly neutral to litmus. Separate the ethereal liquid, add the ether and 950 millilitres (19 fluid ounces) of the alcohol, and filter.

Standard.—Compound spirit of ether has a specific gravity of 0.808 to 0.812. It gives an opalescent solution when mixed with twice its volume of water. The residue obtained on evaporating spontaneously 2 or 3 millilitres on a watch-glass has no unpleasant odour (absence of empyreumatic impurities).

Dose.—For a single administration, 4 to 6 millilitres (1 to 1 $\frac{1}{2}$ fluid drachms); for repeated administration, 1.3 to 2.6 millilitres (20 to 40 minims).

Alcohol content, 63 to 68 per cent. v/v of ethyl alcohol.

SPIRITUS AMMONIÆ FETIDUS

(Sp. Ammon. Fetid.)

Fetid Spirit of Ammonia

	<i>Metric</i>	<i>Imperial</i>
Asafetida	75 g.	1½ oz.
Strong Solution of Ammonia .. .	100 ml.	2 fl. oz.
Alcohol (90 per cent.) .. .	to 1000 ml.	to 20 fl. oz.

Break the asafetida into small pieces and macerate it in 750 millilitres (15 fluid ounces) of the alcohol in a closed vessel for twenty-four hours; then distil until alcoholic vapours cease to be condensed, add to the distillate the strong solution of ammonia and sufficient of the alcohol to produce the required volume.

Standard.—Fetid spirit of ammonia contains not less than 2·72 per cent. w/v of NH_3 . Specific gravity, 0·842 to 0·850.

Assay.—Add 20 millilitres to 50 millilitres of N/1 sulphuric acid and titrate with N/1 sodium hydroxide, using methyl red as indicator; each millilitre of N/1 sulphuric acid is equivalent to 0·01703 gramme of NH_3 .

Dose.—For a single administration, 4 to 6 millilitres (1 to 1½ fluid drachms); for repeated administration, 1·3 to 2·6 millilitres (20 to 40 minims).

Alcohol content, 78 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS AMYGDALÆ AMARÆ

(Sp. Amygdal. Amar.)

Spirit of Bitter Almond*Synonym*—Essence of Bitter Almonds.

	<i>Metric</i>	<i>Imperial</i>
Oil of Bitter Almond without		
Hydrocyanic Acid	62·5 ml.	1¼ fl. oz.
Alcohol (90 per cent.) .. .	to 1000·0 ml.	to 20 fl. oz.
Dissolve.		

Alcohol content, 82 to 85 per cent. v/v of ethyl alcohol.

SPIRITUS ANISI

(Sp. Anis.)

Spirit of Anise

	<i>Metric</i>	<i>Imperial</i>
Oil of Anise	100 ml.	2 fl. oz.
Alcohol (90 per cent.) .. .	to 1000 ml.	to 20 fl. oz.

Dissolve. When not clear, shake with a little purified talc or kaolin, and filter.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS ARMORACIÆ COMPOSITUS

(Sp. Armor. Co.)

Compound Spirit of Horseradish

	<i>Metric</i>	<i>Imperial</i>
Horseradish, scraped	125 g.	2½ oz.
Dried Bitter-Orange Peel, bruised	125 g.	2½ oz.
Nutmeg, bruised	3 g.	26¼ gr.
Alcohol (90 per cent.)	625 ml.	12¼ fl. oz.
Distilled Water	750 ml.	15 fl. oz.

Macerate the horseradish in the distilled water for one hour, add the other ingredients, and distil 1000 millilitres (20 fluid ounces).

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 53 to 59 per cent. v/v of ethyl alcohol.

SPIRITUS CHIRURGICALIS

(Sp. Chir.)

Surgical Spirit

The use of industrial methylated spirit in preparing surgical spirit from the two following formulæ is approved by the Board of Customs and Excise:—

No. 1	<i>Metric</i>	<i>Imperial</i>
Castor Oil	25 ml.	½ fl. oz.
Methyl Salicylate	5 ml.	48 m.
Ethyl Phthalate	20 ml.	192 m.
Industrial Methylated Spirit .. to 1000 ml.		to 20 fl. oz.
Dissolve.		

No. 2	<i>Metric</i>	<i>Imperial</i>
Castor Oil	27·5 ml.	264 m.
Mineral Naphtha	2·5 ml.	24 m.
Ethyl Phthalate	20·0 ml.	192 m.
Industrial Methylated Spirit .. to 1000·0 ml.		to 20 fl. oz.
Dissolve.		

SPIRITUS CINNAMOMI

(Sp. Cinnam.)

Spirit of Cinnamon

	<i>Metric</i>	<i>Imperial</i>
Oil of Cinnamon	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve. When not clear, shake with a little purified talc or kaolin, and filter.

Dose.— 0·3 to 1·2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS COLONIENSIS

(Sp. Colon.)

Cologne Spirit*Synonym*—Aqua Coloniensis.

	<i>Metric</i>	<i>Imperial</i>
Oil of Bergamot	12.5 ml.	120 m.
Oil of Lemon	5.0 ml.	48 m.
Oil of Neroli	2.1 ml.	20 m.
Oil of Rosemary	1.6 ml.	15 m.
Oil of Thyme	0.5 ml.	5 m.
Triple Orange-flower Water ..	45.0 ml.	432 m.
Alcohol (90 per cent.)	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oils in about 900 millilitres (18 fluid ounces) of the alcohol, add the orange-flower water gradually, and then add sufficient alcohol to produce the required volume.

Alcohol content, 80 to 83 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the final product contains 1 per cent. v/v of ethyl phthalate and that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS JUNIPERI

(Sp. Junip.)

Spirit of Juniper

	<i>Metric</i>	<i>Imperial</i>
Oil of Juniper	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve. When not clear, shake with a little purified talc or kaolin, and filter.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS LAVANDULÆ

(Sp. Lavand.)

Spirit of Lavender

	<i>Metric</i>	<i>Imperial</i>
Oil of Lavender	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve. When not clear, shake with a little purified talc or kaolin, and filter.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS LAVANDULÆ COMPOSITUS

(Sp. Lavand. Co.)

Compound Spirit of Lavender*Synonym*—Aqua Lavandulæ.

	<i>Metric</i>	<i>Imperial</i>
Oil of Lavender	31·2 ml.	300 m.
Oil of Bergamot	13·0 ml.	125 m.
Oil of Peppermint .. .	0·5 ml.	5 m.
Oil of Clove	0·8 ml.	7½ m.
Oil of Rose	1·0 ml.	10 m.
Spirit of Nitrous Ether .. .	13·0 ml.	125 m.
Alcohol (90 per cent.) .. .	875·0 ml.	17½ fl. oz.
Distilled Water	to 1000·0 ml.	to 20 fl. oz.

Dissolve the oils in the alcohol, add the spirit of nitrous ether and sufficient distilled water to produce the required volume.

Alcohol content, 76 to 80 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the final product contains 1 per cent. v/v of ethyl phthalate and that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS MENTHOLIS

(Sp. Menthol.)

Spirit of Menthol

	<i>Metric</i>	<i>Imperial</i>
Menthol	50 g.	1 oz.
Alcohol (90 per cent.) .. .	to 1000 ml.	to 20 fl. oz.

Dissolve.

Alcohol content, 84 to 87 per cent. v/v of ethyl alcohol.

SPIRITUS MENTHOLIS COMPOSITUS

(Sp. Menthol. Co.)

Compound Spirit of Menthol

	<i>Metric</i>	<i>Imperial</i>
Camphor	100 g.	2 oz.
Menthol	100 g.	2 oz.
Terebene	100 ml.	2 fl. oz.
Eucalyptol	100 ml.	2 fl. oz.
Alcohol (90 per cent.) .. .	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.— 10 drops, by inhalation.

Alcohol content, 48 to 52 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS MYRCIÆ COMPOSITUS

(Sp. Myrc. Co.)

Compound Spirit of Bay

Synonyms — Spiritus Pimentæ Compositus; Compound Spirit of Pimento.

	<i>Metric</i>	<i>Imperial</i>
Oil of Bay	7.5 ml.	72 m.
Oil of Orange	0.5 ml.	5 m.
Oil of Pimento	0.5 ml.	5 m.
Dry Extract of Quassia	0.9 g.	7½ gr.
Alcohol (90 per cent.)	640.0 ml.	12 fl. oz. 384 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oils and the dry extract of quassia in the alcohol and gradually add sufficient distilled water to produce the required volume; set aside for eight days, add a little purified talc or kaolin, and filter.

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS MYRISTICÆ

(Sp. Myrist.)

Spirit of Nutmeg

	<i>Metric</i>	<i>Imperial</i>
Oil of Nutmeg	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS PULEGII

(Sp. Puleg.)

Spirit of Pulegium

Synonyms—Essence of Pennyroyal; Essentia Pulegii; Essence of Pulegium.

	<i>Metric</i>	<i>Imperial</i>
Oil of Pulegium	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.—0·6 to 1·2 millilitres (10 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS RESORCINOLIS

(Sp. Resorcin.)

Spirit of Resorcinol

Synonyms—Spiritus Capillaris; Lotio Resorcinolis Composita; Spiritus Resorcini; Spirit of Resorcin.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	25 g.	$\frac{1}{2}$ oz.
Castor Oil	25 ml.	$\frac{1}{2}$ fl. oz.
Cologne Spirit	200 ml.	4 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve the resorcinol and castor oil in the Cologne spirit and a portion of the alcohol, and add sufficient of the alcohol to produce the required volume.

Alcohol content, 84 to 87 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS ROSMARINI

(Sp. Rosmarin.)

Spirit of Rosemary

	<i>Metric</i>	<i>Imperial</i>
Oil of Rosemary	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.—0·3 to 1·2 millilitres (5 to 20 minims).

Alcohol content, 79 to 82 per cent. v/v of ethyl alcohol.

SPIRITUS SAPONATUS

(Sp. Sap.)

Soap Spirit

			<i>Metric</i>	<i>Imperial</i>
Soft Soap	650 g.	13 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Alcohol content, 28 to 31 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SPIRITUS SAPONIS KALINI

(Sp. Sap. Kalin.)

Spirit of Potash Soap*Synonym*—Spiritus Saponis Kalini (Hebra).

			<i>Metric</i>	<i>Imperial</i>
Potash Soap	650 g.	13 oz.
Oil of Lavender	3 ml.	29 m.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Alcohol content, 28 to 31 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

SUCCUS ALLII

(Succ. Allii)

Juice of Garlic

			<i>Metric</i>	<i>Imperial</i>
Garlic, fresh	800 g.	16 oz.
Alcohol (90 per cent.)	200 ml.	4 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Bruise the garlic and express the juice; mix the pressed marc with 200 millilitres (4 fluid ounces) of distilled water and again express the liquid, repeating the operation until the volume of the mixed juice and washings amounts to 800 millilitres (16 fluid ounces); add the alcohol and sufficient distilled water to produce the required volume. Allow to stand for not less than fourteen days, and decant or filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SUCCUS CONII

(Succ. Conii)

Juice of Conium*Synonym*—Juice of Hemlock.

Bruise fresh conium leaf and press out the juice; to every three volumes of juice add one volume of alcohol (90 per cent.); set aside for seven days, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SUCCUS HYOSCYAMI

(Succ. Hyoscy.)

Juice of Hyoscyamus

Bruise the fresh leaves and flowering tops of *Hyoscyamus niger* Linn., and press out the juice; to every three volumes of juice add one volume of alcohol (90 per cent.), set aside for seven days, and filter.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SUCCUS SCOPARII

(Succ. Scopar.)

Juice of Scoparium*Synonym*—Juice of Broom.

Bruise fresh scoparium and press out the juice; to every three volumes of juice add one volume of alcohol (90 per cent.), set aside for seven days, and filter.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

SUCCUS TARAXACI

(Succ. Tarax.)

Juice of Taraxacum

Bruise fresh taraxacum root and press out the juice; to every three volumes of juice add one volume of alcohol (90 per cent.), set aside for seven days, and filter.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

SUPPOSITORIA

Suppositories

Suppositories are solid bodies, suitably shaped for anal administration, and uniformly medicated with substances which are usually intended to act locally. They are usually conical, or occasionally torpedo-shaped. The basis employed in making suppositories should be non-irritating, hard enough to be handled, and yet melt readily at body temperature (37°). Unless otherwise specified, suppositories are prepared with oil of theobroma, which melts between 30° and 35°.

When melting oil of theobroma, it is important to remember that overheating will cause a lowering of the solidifying-point, and subsequently the suppositories may set only with difficulty; it is advisable, therefore, to use powdered or shredded oil of theobroma, which melts readily. An alternative basis is the glycerin suppository mass of the British Pharmacopœia. It should only be employed when specified, since the gelatin is incompatible with several substances, including tannins. A small quantity of white beeswax in conjunction with oil of theobroma, sufficient to raise the melting-point to not more than 37°, is sometimes used in the preparation of suppositories containing substances such as phenol or chloral hydrate. This addition may be omitted, except in the case of suppositories containing volatile oil, by using the minimum amount of heat. In tropical and sub-tropical climates, sufficient white beeswax to suit conditions of temperature may be added, in place of an equivalent amount of oil of theobroma, when the suppositories would otherwise be too soft for use.

Suppositories are generally moulded, the moulds holding 1 gramme (15 grains) or 2 grammes (30 grains) of oil of theobroma. Unless otherwise specified, a 1 gramme mould should be employed. A 1 gramme mould will hold about 1·2 grammes (18 grains) of glycerin suppository mass. Dry solid medicaments are first very finely powdered; soft extracts are rubbed smooth with a minimum quantity of water or other suitable liquid. They are then triturated with a small portion of the melted basis, and the resulting mixture is added to the bulk of the basis, the whole being stirred until uniform. The medicated basis, allowed to cool until about to solidify, is poured into a cold and lubricated mould. Almond oil, and a solution of soft soap in alcohol (90 per cent.) (1 in 2) containing about 5 per cent. of glycerin, are frequently employed as mould lubricants. In cases where the use of heat is undesirable, the medicament can be worked into a uniform mass with shredded oil of theobroma and shaped by cold compression in the mould or by means of a suitable machine.

Suppositories should be sent out in partitioned boxes or in shallow boxes lined with waxed paper, and when made with glycerin suppository mass, they should be very slightly greased with oil or liquid paraffin. When made for tropical climates, or when containing volatile ingredients, suppositories should be wrapped separately in tin-foil.

SUPPOSITORIUM ICHTHAMMOLIS

(Supp. Ichtham.)

Ichthammol Suppository*Synonym*—Ammonium Ichthosulphonate Suppository.

	<i>Metric</i>	<i>Imperial</i>
Ichthammol	0.19 g.	3 gr.
Suppository of Glycerin, sufficient to fill a 1 gramme (15 grain) mould.		

Mix the ichthammol with the melted suppository of glycerin, and pour into a mould.

SUPPOSITORIUM NUTRIENS

(Supp. Nutr.)

Nutrient Suppository*Synonyms*—Suppositorium Peptoni; Peptone Suppository.

	<i>Metric</i>	<i>Imperial</i>
Beef Peptone	75.0 g.	7½ oz.
Gelatin	7.5 g.	¾ oz.
Distilled Water	17.5 ml.	1¾ fl. oz.

Soften the gelatin in the water and warm on a water-bath until dissolved; add the beef peptone and pour into moulds of the required size. The quantity of gelatin may be varied if necessary.

SYRUPUS ACACIÆ

(Syr. Acac.)

Syrup of Acacia

	<i>Metric</i>	<i>Imperial</i>
Mucilage of Acacia	250 ml.	5 fl. oz.
Syrup to 1000 ml.		to 20 fl. oz.

Mix.

It should be freshly prepared.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

SYRUPUS ACIDI HYDRIODICI

(Syr. Acid. Hydriod.)

Syrup of Hydriodic Acid

	<i>Metric</i>	<i>Imperial</i>
Dilute Hydriodic Acid	100 ml.	2 fl. oz.
Distilled Water	50 ml.	1 fl. oz.
Syrup to 1000 ml.		to 20 fl. oz.

Mix.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

SYRUPUS ACIDI LACTICI

(Syr. Acid. Lact.)

Syrup of Lactic Acid

				<i>Metric</i>	<i>Imperial</i>
Lactic Acid	25 ml.	$\frac{1}{2}$ fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).**SYRUPUS ALLII**

(Syr. Allii)

Syrup of Garlic

				<i>Metric</i>	<i>Imperial</i>
Juice of Garlic	200 ml.	4 fl. oz.
Sucrose	800 g.	16 oz.
Dilute Acetic Acid	200 ml.	4 fl. oz.
Distilled Water	200 ml.	4 fl. oz.

Mix the dilute acetic acid and the distilled water, and dissolve the sucrose in the mixture in a tared vessel with the aid of heat; allow to cool, and make up to the original weight, if necessary, by the addition of distilled water; add the juice of garlic.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).**SYRUPUS ALTHÆÆ**

(Syr. Alth.)

Syrup of Althæa*Synonym*—Syrup of Marshmallow.

				<i>Metric</i>	<i>Imperial</i>
Althæa	40.0 g.	350 gr.
Sucrose	900.0 g.	18 oz.
Chloroform	2.5 ml.	24 m.
Distilled Water	560.0 ml.	11 fl. oz. 96 m.

Cut the althæa into slices and macerate with the water for twelve hours, then strain, press, and filter into a tared vessel; dissolve the sucrose in the filtrate, heating the syrup to boiling, allow to cool, replace any water lost by evaporation, and strain through flannel; add the chloroform, and shake until dissolved.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms.)

SYRUPUS ANISI

(Syr. Anis.)

Syrup of Anise

	<i>Metric</i>	<i>Imperial</i>
Concentrated Anise Water ..	125 ml.	2½ fl. oz.
Syrup to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS APOMORPHINÆ**

(Syr. Apomorph.)

Syrup of Apomorphine

	<i>Metric</i>	<i>Imperial</i>
Apomorphine Hydrochloride ..	0·5 g.	4½ gr.
Dilute Hydrochloric Acid ..	2·5 ml.	24 m.
Alcohol (90 per cent.) ..	45·0 ml.	432 m.
Distilled Water	45·0 ml.	432 m.
Syrup to 1000·0 ml.	to 20 fl. oz.

Dissolve the apomorphine hydrochloride in the alcohol, distilled water and dilute hydrochloric acid, previously mixed; then add sufficient syrup to produce the required volume.

It should be **stored** protected from light.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS AROMATICUS**

(Syr. Aromat.)

Aromatic Syrup

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Orange ..	62·5 ml.	1¼ fl. oz.
Cinnamon Water	250·0 ml.	5 fl. oz.
Syrup to 1000·0 ml.	to 20 fl. oz.

Mix the liquid extract of orange and cinnamon water, shake the mixture with a little purified talc or kaolin, filter, and add to the filtrate sufficient syrup to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS AURANTII FLORIS

(Syr. Aurant. Flor.)

Syrup of Orange-flower

	<i>Metric</i>	<i>Imperial</i>
Triple Orange-flower Water ..	150 ml.	3 fl. oz.
Sucrose	300 g.	6 oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Mix the triple orange-flower water with the sucrose in a closed vessel and allow to stand in a moderately warm place, shaking occasionally, until dissolved; then add sufficient syrup to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS BROMOFORMI COMPOSITUS

(Syr. Bromof. Co.)

Compound Syrup of Bromoform

	<i>Metric</i>	<i>Imperial</i>
Bromoform .. .	1.6 ml.	15 m.
Codeine .. .	0.5 g.	4½ gr.
Tincture of Aconite .. .	2.1 ml.	20 m.
Spirit of Bitter Almond .. .	1.0 ml.	10 m.
Alcohol (90 per cent.) .. .	50.0 ml.	1 fl. oz.
Cherry-laurel Water .. .	50.0 ml.	1 fl. oz.
Glycerin .. .	100.0 ml.	2 fl. oz.
Syrup of Red Poppy .. .	150.0 ml.	3 fl. oz.
Syrup of Tolu .. .	to 1000.0 ml.	to 20 fl. oz.

Dissolve the codeine in the alcohol, dissolve the bromoform in the solution, and add the tincture of aconite, spirit of bitter almond and glycerin; add the solution gradually, with constant agitation, to a mixture of the syrup of red poppy, cherry-laurel water and 500 millilitres (10 fluid ounces) of syrup of tolu, and finally add sufficient syrup of tolu to produce the required volume.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

SYRUPUS CALCII CHLORIDI

(Syr. Calc. Chlorid.)

Syrup of Calcium Chloride

Synonyms—Exilir Calcii Chloridi; Elixir of Calcium Chloride.

	<i>Metric</i>	<i>Imperial</i>
Calcium Chloride ..	125 g.	2½ oz.
Distilled Water ..	150 ml.	3 fl. oz.
Syrup of Lemon ..	to 1000 ml.	to 20 fl. oz.

Dissolve the calcium chloride in the distilled water, and add sufficient syrup of lemon to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS CALCII HYPOPHOSPHITIS

(Syr. Calc. Hypophosph.)

Syrup of Calcium Hypophosphite

	<i>Metric</i>	<i>Imperial</i>
Calcium Hypophosphite ..	18.3 g.	160 gr.
Hypophosphorous Acid ..	2.5 ml.	24 m.
Sucrose ..	800.0 g.	16 oz.
Distilled Water ..	to 1000.0 ml.	to 20 fl. oz.

Dissolve the calcium hypophosphite in 450 millilitres (9 fluid ounces) of the distilled water, filter if necessary, add the sucrose and dissolve with the aid of gentle heat; add the hypophosphorous acid and sufficient distilled water to produce the required volume.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

SYRUPUS CALCII LACTOPHOSPHATIS

(Syr. Calc. Lactophosph.)

Syrup of Calcium Lactophosphate

	<i>Metric</i>	<i>Imperial</i>
Calcium Lactate ..	75 g.	1½ oz.
Phosphoric Acid ..	29 ml.	278 m.
Triple Orange-flower Water ..	25 ml.	½ fl. oz.
Sucrose ..	700 g.	14 oz.
Distilled Water ..	to 1000 ml.	to 20 fl. oz.

Mix the calcium lactate with 400 millilitres (8 fluid ounces) of the distilled water, add the phosphoric acid, stir until solution is complete, and then add the orange-flower water; dissolve the sucrose in the mixture without the aid of heat, add sufficient distilled water to produce the required volume, and filter.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

SYRUPUS CALCII LACTOPHOSPHATIS CUM FERRO

(Syr. Calc. Lactophosph. c. Ferr.)

Syrup of Calcium Lactophosphate with Iron

Synonym—Syrupus Ferri et Calcii Lactophosphatis.

	<i>Metric</i>	<i>Imperial</i>
Iron Lactate ..	8.6 g.	75 gr.
Potassium Citrate ..	8.6 g.	75 gr.
Distilled Water ..	62.5 ml.	1¼ fl. oz.
Syrup of Calcium Lactophosphate	to 1000.0 ml.	to 20 fl. oz.

Dissolve the iron lactate and potassium citrate in the water with the aid of heat, and add the solution quickly to about 900 millilitres (18 fluid ounces) of the syrup of calcium lactophosphate; add sufficient syrup of calcium lactophosphate to produce the required volume, and set the mixture aside until clear.

It should be **stored** in well-filled bottles.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS CAMPHORÆ COMPOSITUS

(Syr. Camph. Co.)

Compound Syrup of Camphor

	<i>Metric</i>	<i>Imperial</i>
Camphor	0.46 g.	4 gr.
Oil of Anise	0.42 ml.	4 m.
Benzoic Acid	0.63 g.	5 $\frac{1}{2}$ gr.
Glacial Acetic Acid	5.7 ml.	55 m.
Tincture of Opium	16.7 ml.	160 m.
Vinegar of Ipecacuanha	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Vinegar of Squill	62.5 ml.	1 $\frac{1}{4}$ fl. oz.
Sucrose	700.0 g.	14 oz.
Solution of Burnt Sugar	6.3 ml.	60 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the camphor, oil of anise and benzoic acid in the tincture of opium, mix with the syrup prepared by dissolving the sucrose in 400 millilitres (8 fluid ounces) of hot distilled water and cooling, add the other ingredients and sufficient distilled water to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS CASCARÆ AROMATICUS

(Syr. Casc. Aromat.)

Aromatic Syrup of Cascara

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Cascara Sagrada	400 ml.	8 fl. oz.
Tincture of Orange	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	50 ml.	1 fl. oz.
Cinnamon Water	150 ml.	3 fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS CERASI

(Syr. Ceras.)

Syrup of Cherry

Press a sufficient quantity of red cherry to yield 400 grammes (8 ounces) of juice; add 600 grammes (12 ounces) of sucrose, dissolve with the aid of heat, cool, replace the water lost by evaporation, and strain.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS CHLORALIS

(Syr. Chloral.)

Syrup of Chloral

	<i>Metric</i>	<i>Imperial</i>
Chloral Hydrate	200 g.	4 oz.
Distilled Water	200 ml.	4 fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Dissolve the chloral hydrate in the distilled water, and add sufficient syrup to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS CODEINÆ PHOSPHATIS

(Syr. Codein. Phosph.)

Syrup of Codeine Phosphate

	<i>Metric</i>	<i>Imperial</i>
Codeine Phosphate	5 g.	43 $\frac{3}{4}$ gr.
Distilled Water	20 ml.	192 m.
Syrup	to 1000 ml.	to 20 fl. oz.

Dissolve the codeine phosphate in the distilled water, and add sufficient syrup to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS CREOSOTI COMPOSITUS

(Syr. Creosot. Co.)

Compound Syrup of Creosote

	<i>Metric</i>	<i>Imperial</i>
Creosote	16.7 ml.	160 m.
Spirit of Chloroform	50.0 ml.	1 fl. oz.
Glycerin	333.3 ml.	6 fl. oz. 320 m.
Syrup of Pine	250.0 ml.	5 fl. oz.
Syrup	to 1000.0 ml.	to 20 fl. oz.

Dissolve the creosote in the spirit of chloroform. add to the glycerin and syrup of pine previously mixed, and add sufficient syrup to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS CROCI

(Syr. Croc.)

Syrup of Saffron

		<i>Metric</i>	<i>Imperial</i>
Glycerin of Saffron	125 ml.	2½ fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Mix.

It should be **stored** protected from light.**SYRUPUS FERRI BROMIDI**

(Syr. Ferr. Brom.)

Syrup of Ferrous Bromide

		<i>Metric</i>	<i>Imperial</i>
Iron	25 g.	½ oz.
Bromine	60 g.	1 oz. 87½ gr.
Sucrose	700 g.	14 oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Dissolve the sucrose in 300 millilitres (6 fluid ounces) of distilled water with the aid of heat. Place the iron with 200 millilitres (4 fluid ounces) of distilled water in a glass flask having a capacity of at least 1000 millilitres (20 fluid ounces), and surround it with cold water. Then add the bromine in successive quantities and shake occasionally until the froth becomes white and the reaction is complete. Filter the solution into the warm syrup, and, if necessary, add sufficient distilled water to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS FERRI BROMIDI CUM QUININA**

(Syr. Ferr. Brom. c. Quinin.)

Syrup of Ferrous Bromide with Quinine

		<i>Metric</i>	<i>Imperial</i>
Quinine Dihydrobromide	20 g.	175 gr.
Dilute Hydrobromic Acid	20 ml.	192 m.
Distilled Water	80 ml.	1 fl. oz. 288 m.
Syrup of Ferrous Bromide	to 1000 ml.	to 20 fl. oz.

Dissolve the quinine dihydrobromide in the dilute hydrobromic acid and the distilled water with the aid of gentle heat, then add sufficient syrup of ferrous bromide to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS FERRI BROMIDI CUM QUININA ET STRYCHNINA

(Syr. Ferr. Brom. c. Quinin. et Strych.)

Syrup of Ferrous Bromide with Quinine and Strychnine

	<i>Metric</i>	<i>Imperial</i>
Strychnine, in powder	0.29 g.	2½ gr.
Quinine Dihydrobromide	20.0 g.	175 gr.
Dilute Hydrobromic Acid	20.0 ml.	192 m.
Distilled Water	80.0 ml.	1 fl. oz. 288 m.
Syrup of Ferrous Bromide	to 1000.0 ml.	to 20 fl. oz.

Dissolve the strychnine and the quinine dihydrobromide in the dilute hydrobromic acid and the distilled water with the aid of gentle heat, and add sufficient syrup of ferrous bromide to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS FERRI HYPOPHOSPHITIS

(Syr. Ferr. Hypophosph.)

Syrup of Iron Hypophosphite

	<i>Metric</i>	<i>Imperial</i>
Solution of Iron Hypophosphite	200 ml.	4 fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS FERRI PHOSPHATIS

(Syr. Ferr. Phosph.)

Syrup of Ferrous Phosphate

	<i>Metric</i>	<i>Imperial</i>
Solution of Ferrous Phosphate	125 ml.	2½ fl. oz.
Syrup	875 ml.	17½ fl. oz.
Mix.		

It should be **stored** in well-filled bottles.

Standard.—Syrup of ferrous phosphate, determined by the method of the British Pharmacopœia for iron in Syrupus Ferri Phosphatis Compositus, using about 10 grammes accurately weighed, contains iron equivalent to not less than 1.7 per cent. and not more than 1.9 per cent. w/v of $\text{Fe}_3(\text{PO}_4)_2$.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS FICORUM

(Syr. Fic.)

Syrup of Figs

	<i>Metric</i>	<i>Imperial</i>
Fig, cut small	400 g.	8 oz.
Sucrose	675 g.	13½ oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add the fig to 1000 millilitres (20 fluid ounces) of boiling distilled water, and digest at a gentle heat for one hour; then strain, express, and wash the pulp with sufficient warm water to produce 1000 millilitres (20 fluid ounces); evaporate the liquid to one-half its volume, dissolve the sucrose in the concentrated liquid, and add sufficient distilled water to produce the required volume.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS FICORUM COMPOSITUS

(Syr. Fic. Co.)

Compound Syrup of Figs

Synonyms—Syrupus Ficorum Aromaticus; Aromatic Syrup of Figs.

	<i>Metric</i>	<i>Imperial</i>
Compound Tincture of Rhubarb	50.0 ml.	1 fl. oz.
Liquid Extract of Senna	100.0 ml.	2 fl. oz.
Elixir of Cascara Sagrada	50.0 ml.	1 fl. oz.
Syrup of Figs	to 1000.0 ml.	to 20 fl. oz.

Mix.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS GLYCEROPHOSPHATUM COMPOSITUS

(Syr. Glycerophosph. Co.)

Compound Syrup of Glycerophosphates

Synonym—Syrupus Glycerophosphatum Ruber.

	<i>Metric</i>	<i>Imperial</i>
Calcium Glycerophosphate	22.9 g.	200 gr.
Magnesium Glycerophosphate	11.4 g.	100 gr.
Iron Glycerophosphate	5.7 g.	50 gr.
Solution of Potassium Glycero- phosphate	22.9 g.	200 gr.
Solution of Sodium Glycero- phosphate	22.9 g.	200 gr.
Potassium Citrate	11.4 g.	100 gr.
Glycerophosphoric Acid	20.8 ml.	200 m.
Caffeine	5.7 g.	50 gr.
Strychnine	0.2 g.	1¾ gr.
Glycerin	200.0 ml.	4 fl. oz.
Sucrose	400.0 g.	8 oz.
Solution of Bordeaux B	31.2 ml.	300 m.
Chloroform	2.1 ml.	20 in.
Alcohol (90 per cent.)	4.2 ml.	40 m.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium citrate in 350 millilitres (7 fluid ounces) of distilled water, add the solution of potassium glycerophosphate and solution of sodium glycerophosphate, and dissolve the calcium, magnesium and iron glycerophosphates in the mixture. Add the glycerin, the strychnine dissolved in the glycerophosphoric acid, and the caffeine dissolved in 50 millilitres (1 fluid ounce) of hot distilled water. Filter, if necessary, and dissolve the sucrose in the filtrate without the aid of heat. Add the chloroform dissolved in the alcohol, the solution of bordeaux B and sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS GLYCEROPHOSPHATUM COMPOSITUS CUM MEDULLA RUBRA

(Syr. Glycerophosph. Co. c. Medull. Rub.)

Compound Syrup of Glycerophosphates with Red Bone Marrow

	<i>Metric</i>	<i>Imperial</i>
Compound Syrup of Glycerophosphates	500 ml.	10 fl. oz.
Extract of Red Bone Marrow ..	500 ml.	10 fl. oz.

Mix.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS GLYCEROPHOSPHATUM CUM FORMATIBUS

(Syr. Glycerophosph. c. Format.)

Syrup of Glycerophosphates with Formates

Synonym—Compound Elixir of Glycerophosphates with Formates.

	<i>Metric</i>	<i>Imperial</i>
Calcium Glycerophosphate ..	17.1 g.	150 gr.
Magnesium Glycerophosphate ..	8.6 g.	75 gr.
Iron Glycerophosphate ..	5.7 g.	50 gr.
Solution of Potassium Glycerophosphate	17.1 g.	150 gr.
Solution of Sodium Glycerophosphate	17.1 g.	150 gr.
Potassium Citrate	11.4 g.	100 gr.
Glycerophosphoric Acid ..	20.8 ml.	200 m.
Potassium Formate	50.0 g.	1 oz.
Sodium Formate	50.0 g.	1 oz.
Strychnine	0.2 g.	1½ gr.
Glycerin	200.0 ml.	4 fl. oz.
Sucrose	400.0 g.	8 oz.
Double Chloroform Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium citrate in 400 millilitres (8 fluid ounces) of double chloroform water, add the solution of potassium glycerophosphate and solution of sodium glycerophosphate, and dissolve the calcium, magnesium and iron glycerophosphates and the sodium and potassium formates in the mixture. Add the glycerin and the strychnine dissolved in the glycerophosphoric acid, and filter if necessary. Dissolve the sucrose in the filtrate without the aid of heat, and add sufficient double chloroform water to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS GLYCEROPHOSPHATUM ET PEPSINI COMPOSITUS

(Syr. Glycerophosph. et Pepsin. Co.)

Compound Syrup of Glycerophosphates and Pepsin

Synonym—Syrupus Glycerophosphatum Compositus (Robin).

	<i>Metric</i>	<i>Imperial</i>
Calcium Glycerophosphate ..	22.9 g.	200 gr.
Magnesium Glycerophosphate ..	11.4 g.	100 gr.
Iron Glycerophosphate	5.7 g.	50 gr.
Solution of Potassium Glycero- phosphate	22.9 g.	200 gr.
Solution of Sodium Glycero- phosphate	22.9 g.	200 gr.
Glycerophosphoric Acid	20.8 ml.	200 m.
Potassium Citrate	11.4 g.	100 gr.
Pepsin	6.9 g.	60 gr.
Caffeine	5.7 g.	50 gr.
Oil of Bitter Almond without Hydro- cyanic Acid	0.05 ml.	$\frac{1}{2}$ m.
Vanillin	0.2 g.	$1\frac{1}{4}$ gr.
Tincture of Ignatia	31.2 ml.	300 m.
Chloroform	1.0 ml.	10 m.
Solution of Bordeaux B	31.2 ml.	300 m.
Glycerin	200.0 ml.	4 fl. oz.
Sucrose	400.0 g.	8 oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium citrate in 300 millilitres (6 fluid ounces) of distilled water, add the solution of potassium glycerophosphate and solution of sodium glycerophosphate, and dissolve the calcium, magnesium and iron glycerophosphates in the mixture; add the glycerophosphoric

acid and the pepsin, previously dissolved in 50 millilitres (1 fluid ounce) of distilled water. Then add the glycerin and a solution of the caffeine in 50 millilitres (1 fluid ounce) of hot distilled water, filter if necessary, dissolve the sucrose in the filtrate, add the solution of bordeaux B, followed by the chloroform, vanillin and oil of bitter almond dissolved in the tincture of ignatia, and sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS GLYCEROPHOSPHATUM FLAVUS

(Syr. Glycerophosph. Flav.)

Yellow Syrup of Glycerophosphates

	<i>Metric</i>	<i>Imperial</i>
Calcium Glycerophosphate ..	22.9 g.	200 gr.
Magnesium Glycerophosphate ..	11.4 g.	100 gr.
Iron Glycerophosphate	5.7 g.	50 gr.
Solution of Potassium Glycerophosphate	22.9 g.	200 gr.
Solution of Sodium Glycerophosphate	22.9 g.	200 gr.
Potassium Citrate	11.4 g.	100 gr.
Glycerophosphoric Acid ..	20.8 ml.	200 m.
Caffeine	5.7 g.	50 gr.
Glycerin	200.0 ml.	4 fl. oz.
Sucrose	400.0 g.	8 oz.
Vanillin	0.1 g.	1 gr.
Chloroform	2.1 ml.	20 m.
Alcohol (90 per cent.)	4.2 ml.	40 m.
Compound Solution of Tartrazine ..	10.4 ml.	100 m.
Cinnamon Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium citrate in 350 millilitres (7 fluid ounces) of cinnamon water, add the solution of potassium glycerophosphate and solution of sodium glycerophosphate and dissolve the calcium, magnesium and iron glycerophosphates in the mixture. Add the glycerophosphoric acid, the glycerin, and the caffeine dissolved in 50 millilitres (1 fluid ounce) of hot cinnamon water. Filter, if necessary, and dissolve the sucrose in the filtrate without the aid of heat. Add the vanillin and chloroform dissolved in the alcohol, the compound solution of tartrazine, and sufficient cinnamon water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS HYPOPHOSPHITUM COMPOSITUS

(Syr. Hypophosph. Co.)

Compound Syrup of Hypophosphites*Synonyms*—Syrupus Ferri Hypophosphitis Compositus; Compound Syrup of Iron Hypophosphite.

		<i>Metric</i>	<i>Imperial</i>
Calcium Hypophosphite	..	9.1 g.	80 gr.
Manganese Hypophosphite	..	4.6 g.	40 gr.
Potassium Hypophosphite	..	4.6 g.	40 gr.
Quinine	2.2 g.	19 gr.
Strychnine	0.11 g.	1 gr.
Sucrose	700.0 g.	14 oz.
Hypophosphorous Acid	..	12.5 ml.	120 m.
Solution of Iron Hypophosphite	..	50.0 ml.	1 fl. oz.
Double Chloroform Water	to	1000.0 ml.	to 20 fl. oz.

Triturate the quinine and strychnine with a small quantity of double chloroform water, add the hypophosphorous acid, and when the alkaloids have dissolved, add to the calcium, manganese and potassium hypophosphites previously dissolved in 400 millilitres (8 fluid ounces) of double chloroform water; add the solution of iron hypophosphite, dissolve the sucrose in the liquid without the aid of heat, and add sufficient double chloroform water to produce the required volume; strain through flannel.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS IODOTANNICUS

(Syr. Iodotann.)

Iodotannic Syrup

		<i>Metric</i>	<i>Imperial</i>
Iodine	10 g.	87½ gr.
Tannic Acid	10 g.	87½ gr.
Alcohol (90 per cent.)	..	125 ml.	2½ fl. oz.
Syrup	500 g.	10 oz.
Syrup of Lemon	to 1000 g.	to 20 oz.

Dissolve the iodine in the alcohol, add the tannic acid, the syrup, and 300 grammes (6 ounces) of syrup of lemon, and heat the mixture nearly to boiling until no free iodine can be detected by the starch test; cool, and add sufficient syrup of lemon to produce the required weight.

Dose.—1 to 4 millilitres (¼ to 1 fluid drachm).

SYRUPUS IODOTANNICUS CUM PHOSPHATE

(Syr. Iodotann. c. Phosph.)

Iodotannic Syrup with Phosphate

		<i>Metric</i>	<i>Imperial</i>
Calcium Carbonate	15 g.	131½ gr.
Phosphoric Acid	30 ml.	288 m.
Iodotannic Syrup to 1000 ml.		to 20 fl. oz.

Mix the calcium carbonate with 300 millilitres (6 fluid ounces) of the iodotannic syrup, add the phosphoric acid, and mix; warm to about 50° to remove the carbon dioxide, stirring thoroughly; cool and add sufficient iodotannic syrup to produce the required volume.

Dose.— 1 to 4 millilitres (¼ to 1 fluid drachm).

SYRUPUS IPECACUANHÆ

(Syr. Ipecac.)

Syrup of Ipecacuanha

		<i>Metric</i>	<i>Imperial</i>
Vinegar of Ipecacuanha	500 ml.	10 fl. oz.
Sucrose	750 g.	15 oz.
Distilled Water to 1000 ml.		to 20 fl. oz.

Dissolve the sucrose in the vinegar of ipecacuanha with the aid of gentle heat, and add sufficient distilled water to produce the required volume.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

SYRUPUS MARRUBII

(Syr. Marrub.)

Syrup of Horehound

		<i>Metric</i>	<i>Imperial</i>
Horehound	425 g.	8½ oz.
Sucrose	850 g.	17 oz.
Distilled Water, boiling	a sufficient quantity	

Digest the horehound for one hour, on a water-bath, with sufficient boiling distilled water to cover it, then strain, press, evaporate on the water-bath to about 450 millilitres (9 fluid ounces), cool, and filter. Dissolve the sucrose in the filtrate with the aid of gentle heat, and add sufficient distilled water to yield a syrup having, when cold, a specific gravity of 1.33.

Dose.— 2 to 4 millilitres (½ to 1 fluid drachm).

SYRUPUS MENTHÆ PIPERITÆ

(Syr. Menth. Pip.)

Syrup of Peppermint

	<i>Metric</i>	<i>Imperial</i>
Concentrated Peppermint Water	125 ml	2½ fl oz
Syrup	875 ml.	17½ fl oz.
Mix		

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).**SYRUPUS MORI**

(Syr. Mori)

Syrup of Mulberry

	<i>Metric</i>	<i>Imperial</i>
Mulberry	a sufficient quantity.	
Alcohol (90 per cent.) .. .	62.5 ml.	1¼ fl. oz.
Sucrose	900.0 g.	18 oz.

Press a sufficient quantity of mulberry to yield 500 millilitres (10 fluid ounces) of juice; heat to boiling-point, cool, and filter. Dissolve the sucrose in the filtrate with the aid of heat, cool, replace the water lost by evaporation and add the alcohol.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS PAPAVERIS**

(Syr. Papav.)

Syrup of Poppy

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Poppy .. .	125 ml.	2½ fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS PICIS LIQUIDÆ**

(Syr. Pic. Liq.)

Syrup of Tar

	<i>Metric</i>	<i>Imperial</i>
Tar	5.0 g.	43¾ gr.
Alcohol (90 per cent.) .. .	52.5 ml.	1 fl. oz. 24 m.
Sucrose	850.0 g.	17 oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Mix the tar intimately, in a mortar, with 10 grammes ($87\frac{1}{2}$ grains) of washed sand, add 100 millilitres (2 fluid ounces) of distilled water, knead the mass thoroughly with the pestle, pour off and reject the aqueous solution, and exhaust the residue with the alcohol; mix 50 grammes (1 ounce) of the sucrose with 10 grammes ($87\frac{1}{2}$ grains) of light magnesium carbonate, and triturate the mixture with the alcoholic solution; add 400 millilitres (8 fluid ounces) of distilled water, stir occasionally during two hours, filter, dissolve the remaining sucrose in the filtrate with the aid of gentle heat, strain, and add sufficient distilled water to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS PINI

(Syr. Pini)

Syrup of Pine

	<i>Metric</i>	<i>Imperial</i>
Oil of Pumilio Pine	6.25 ml.	60 m.
Alcohol (90 per cent.)	125.0 ml.	2½ fl. oz.
Glycerin	250.0 ml.	5 fl. oz.
Compound Solution of Tartrazine	10.4 ml.	100 m.
Sucrose	500.0 g.	10 oz.
Distilled Water	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oil of pumilio pine in the alcohol, add the glycerin and 25 grammes ($\frac{1}{2}$ ounce) of purified talc or kaolin, and add, in small portions, 300 millilitres (6 fluid ounces) of distilled water, shaking between each addition. Filter, dissolve the sucrose in the filtrate with the aid of gentle heat, add the compound solution of tartrazine, and sufficient distilled water to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS PINI ALBI COMPOSITUS

(Syr. Pini Alb. Co.)

Compound Syrup of White Pine

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of White Pine	50 ml.	1 fl. oz.
Liquid Extract of Squill	40 ml.	384 m.
Ammonium Chloride	25 g.	½ oz.
Syrup of Tar	200 ml.	4 fl. oz.
Glycerin	100 ml.	2 fl. oz.
Sucrose	500 g.	10 oz.
Solution of Bordeaux B	5 ml.	48 m.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix the liquid extract of white pine, liquid extract of squill, solution of bordeaux B and ammonium chloride with 300 millilitres (6 fluid ounces) of distilled water, and allow to stand for twenty-four hours. Filter, add the syrup of tar and glycerin, dissolve the sucrose in the product without the aid of heat, add, if necessary, sufficient distilled water to produce the required volume, and strain.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS POTASSII BROMIDI ET PILOCARPINÆ

(Syr. Pot. Brom. et Pilocarp.)

Syrup of Potassium Bromide and Pilocarpine

	<i>Metric</i>	<i>Imperial</i>
Potassium Bromide	100.0 g.	2 oz.
Pilocarpine Hydrobromide ..	0.06 g.	$\frac{1}{2}$ gr.
Glycerin	100.0 ml.	2 fl. oz.
Syrup of Orange	to 1000.0 ml.	to 20 fl. oz.

Dissolve the potassium bromide and the pilocarpine hydrobromide in 800 millilitres (16 fluid ounces) of the syrup of orange with the aid of gentle heat, add the glycerin and sufficient syrup of orange to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

SYRUPUS RHAMNI

(Syr. Rham.)

Syrup of Buckthorn

	<i>Metric</i>	<i>Imperial</i>
Buckthorn	a sufficient quantity	
Strong Tincture of Ginger ..	5.2 ml.	50 m.
Oil of Pimento	0.1 ml.	1 m.
Alcohol (90 per cent.)	31.2 ml.	300 m.
Sucrose	650.0 g.	13 oz.
Distilled Water	to 1000.0 g.	to 20 oz.

Press a sufficient quantity of buckthorn to yield 500 millilitres (10 fluid ounces) of juice, and evaporate to 300 millilitres (6 fluid ounces); set aside for twelve hours; filter, dissolve the sucrose in the filtrate with the aid of heat, strain, and cool. Mix the strong tincture of ginger and the oil of pimento with the alcohol, mix the solution with the syrup, and add sufficient distilled water to produce the required weight.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS RHEI

(Syr. Rhei)

Syrup of Rhubarb

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Rhubarb ..	70.0 ml.	1 fl. oz. 192 m.
Oil of Coriander	0.5 ml.	5 m.
Syrup	to 1000.0 ml.	to 20 fl. oz.

Dissolve the oil of coriander in the liquid extract, and add sufficient syrup to produce the required volume.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

SYRUPUS RHÆADOS

(Syr. Rhæad.)

Syrup of Red-Poppy

	<i>Metric</i>	<i>Imperial</i>
Red-Poppy Petal, dried ..	52 g.	1 oz. 17½ gr.
Sucrose	720 g.	14 oz. 175 gr.
Alcohol (90 per cent.) ..	50 ml.	1 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Add the red-poppy petal, gradually, to 400 millilitres (8 fluid ounces) of distilled water kept hot upon a water-bath, stirring frequently, remove the vessel from the water-bath, and infuse for twelve hours; press out the liquid, strain, add the sucrose, and dissolve with the aid of gentle heat; allow to cool, and add the alcohol and sufficient distilled water to produce the required volume.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS RIBIS NIGRI

(Syr. Rib. Nig.)

Syrup of Black Currant

	<i>Metric</i>	<i>Imperial</i>
Black Currant	a sufficient quantity	
Red Cherry	a sufficient quantity	
Sucrose	600 g.	12 oz.

Press a sufficient quantity of a mixture of 100 parts of black currant and 15 parts of red cherry to yield 400 grammes (8 ounces) of juice; add the sucrose, heat until dissolved, cool, replace the water lost by evaporation, and strain.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS RIBIS RUBRI

(Syr. Rib. Rub.)

Syrup of Red Currant

				<i>Metric</i>	<i>Imperial</i>
Red Currant	a sufficient quantity	
Red Cherry	a sufficient quantity	
Sucrose	600 g.	12 oz.

Press a sufficient quantity of a mixture of 100 parts of red currant and 15 parts of red cherry to yield 400 grammes (8 ounces) of juice; add the sucrose, heat until dissolved, cool, replace the water lost by evaporation, and strain.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS ROSÆ

(Syr. Ros.)

Syrup of Rose

				<i>Metric</i>	<i>Imperial</i>
Red-Rose Petal, dried	50.0 g.	1 oz.
Dilute Sulphuric Acid	13.5 ml.	130 m.
Sucrose	a sufficient quantity	
Distilled Water, boiling	500.0 ml.	10 fl. oz.

Infuse the red-rose petal in the distilled water for two hours; strain, press, heat the infusion to boiling, filter, add to the filtrate twice its weight of sucrose, and dissolve with the aid of heat; cool, replace the water lost by evaporation, add the dilute sulphuric acid, and mix.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS SUCCI LIMONIS

(Syr. Succ. Limon.)

Syrup of Lemon Juice

				<i>Metric</i>	<i>Imperial</i>
Lemon Peel, in thin slices or grated				20 g.	175 gr.
Lemon Juice, fresh	500 ml.	10 fl. oz.
Sucrose	760 g.	15 oz. 87½ gr.
Alcohol (90 per cent.)	a sufficient quantity	

Macerate the lemon peel in 30 millilitres (288 minims) of the alcohol for seven days, press, filter, and add sufficient of the alcohol to produce 40 millilitres (384 minims); clarify the lemon juice by subsidence or filtration, add the sucrose, and dissolve with the aid of gentle heat; cool, add the alcoholic liquid, and mix.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

SYRUPUS TRIPLEX

(Syr. Trip.)

Triple Syrup

	<i>Metric</i>	<i>Imperial</i>
Compound Syrup of Ferrous Phosphate	250 ml.	5 fl. oz.
Compound Syrup of Hypophosphites	250 ml.	5 fl. oz.
Syrup of Ferrous Phosphate with Quinine and Strychnine ..	250 ml.	5 fl. oz.

Mix.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).**SYRUPUS TUSSILAGINIS**

(Syr. Tussilag.)

Syrup of Coltsfoot

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Coltsfoot ..	250 ml.	5 fl. oz.
Syrup	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).**TABELLÆ****Tablets***Synonym*—Tablettæ.

Tablets are usually disc-shaped, and consist of substances in moulded or compressed form. **Moulded tablets**, or tablet triturates, are made from fine powders, and generally consist of potent remedies, usually diluted with lactose or dextrose. The powder is moistened with alcohol, moulded into tablets by pressure with a spatula into circular holes in a vulcanite or metal plate, and dried; friable tablets result, which are very readily soluble. This type of tablet is generally used for hypodermic medication.

Compressed tablets consist of medicinal substances, with or without diluent, in a dry, granular condition, compressed by means of punches in suitable dies. The material is granulated by moistening with syrup, mucilage, gelatin solution, water, or by any suitable excipient. The powder should be made coherent, without making it so damp as to adhere to the meshes of a suitable sieve (usually a No. 16) when shaken or gently rubbed through. The granules thus formed are exposed to the air for a few hours, and when thoroughly dry, again passed through a No. 16 sieve, but any fine powder present need not be

sifted from the granules; the material is then ready for compression. It is generally necessary to add a small proportion of lubricant to prevent the granules sticking to the punches or dies. The lubricant may consist of stearic acid, boric acid, liquid paraffin, or oil of theobroma; wherever possible, the use of a lubricant should be avoided. When the tablets are to be crushed to a powder before administration, the addition of a small quantity of starch powder to the material before granulation is desirable, since it ensures a smooth powder free from grittiness. Spontaneous drying of the granules is preferable, but if heat is applied, a temperature of 45° should not be exceeded. Granulation is necessary, as a rule, to secure an easy and uniform flow from the hopper to the die; it also contributes to the production of sound tablets by the interlocking of the granules which takes place on compression. However, such crystalline substances as potassium chlorate and potassium bromide, after passing through a No. 16 sieve, require no other treatment than a little drying before compression.

Compressed tablets are less readily soluble than moulded tablets. When they are composed of insoluble material, it is desirable that they should disintegrate within a reasonable time when dropped into water. This disintegration can be obtained by adding dry starch to the granules before compressing. Half a grain of starch will usually suffice to disintegrate a 5 grain tablet. Tablets composed of readily soluble substances, such as ammonium bromide, hexamine and potassium bromide, should be crushed and dissolved in water before administration.

Chocolate tablets are usually made in the same way as ordinary compressed tablets, but a proportion of sucrose and chocolate powder is added to the medicament before granulation.—

When the proportion of medicament to be contained in each tablet is not stated by the prescriber, the following quantity should be dispensed. The tablets may be made up to any suitable weight with sucrose, chocolate powder, or other inert base, and may, if desired, be sugar, chocolate, pearl, or enteric coated.

Tabellæ Acidi Acetylsalicylici.—Acetylsalicylic acid, 0·3 gramme (5 grains).

Tabellæ Acriflavinae.—Acriflavine, 0·03 gramme ($\frac{1}{2}$ grain), in chocolate basis.

Tabellæ Aloini.—Aloin, 0·03 gramme ($\frac{1}{2}$ grain).

Tabellæ Amidopyrinae.—Amidopyrine, 0·3 gramme (5 grains).

Tabellæ Ammonii Bromidi.—Ammonium bromide, 0·3 gramme (5 grains).

Tabellæ Barbitoni.—Barbitone, 0·3 gramme (5 grains).

Tabellæ Barbitoni Solubilis.—Soluble barbitone, 0·3 gramme (5 grains).

Tabellæ Betanaphtholis.—Betanaphthol, 0·3 gramme (5 grains).

Tabellæ Bismuthi Carbonatis.—Bismuth carbonate, 0·3 gramme (5 grains).

Tabellæ Caffeinæ.—Caffeine, 0·06 gramme (1 grain).

Tabellæ Calcii et Sodii Lactatis.—Calcium sodium lactate, 0·5 gramme ($7\frac{1}{2}$ grains).

Tabellæ Calcii Lactatis.—Calcium lactate, 0·3 gramme (5 grains).

Tabellæ Calcis Sulphuratæ. (*Syn.*—**Tabellæ Calcii Sulphidi.**)—Sulphurated lime, 0·03 gramme ($\frac{1}{2}$ grain).

Tabellæ Cascaræ Sagradæ.—Dry extract of cascara sagrada, 0·12 gramme (2 grains).

Tabellæ Cerevisiæ Fermenti.—Dried yeast, 0·3 gramme (5 grains).

Tabellæ Cinchopheni.—Cinchophen, 0·3 gramme (5 grains).

Tabellæ Digitalis Pulveratæ.—Powdered digitalis, 0·06 gramme (1 grain).

Tabellæ Ephedrinæ Hydrochloridi.—Ephedrine hydrochloride, 0·03 gramme ($\frac{1}{2}$ grain).

Tabellæ Erythritylis Tetranitratis Diluti.—Diluted erythrityl tetranitrate, 0·06 gramme (1 grain), in chocolate basis.

Tabellæ Euflavinæ.—Euflavine, 0·03 gramme ($\frac{1}{2}$ grain), in chocolate basis.

Tabellæ Guaiacolis Carbonatis.—Guaiacol carbonate, 0·3 gramme (5 grains).

Tabellæ Hexaminæ.—Hexamine, 0·3 gramme (5 grains).

Tabellæ Methylsulphonalis.—Methylsulphonal, 0·3 gramme (5 grains).

Tabellæ Methylthioninæ Hydrochloridi.—Methylene blue, 0·12 gramme (2 grains).

Tabellæ Papavereti.—Papaveretum, 0·01 gramme ($\frac{1}{10}$ grain).

Tabellæ Parathyroidei.—Parathyroid, 0·006 gramme ($\frac{1}{100}$ grain).

Tabellæ Phenacetini.—Phenacetin, 0·3 gramme (5 grains).

Tabellæ Phenazoni.—Phenazone, 0·3 gramme (5 grains).

Tabellæ Phenobarbitoni.—Phenobarbitone, 0·03 gramme ($\frac{1}{2}$ grain).

Tabellæ Phenobarbitoni Solubilis.—Soluble phenobarbitone, 0·03 gramme ($\frac{1}{2}$ grain).

Tabellæ Phenolphthaleini.—Phenolphthalein, 0·12 gramme (2 grains), in chocolate basis.

Tabellæ Potassii Bromidi.—Potassium bromide, 0·3 gramme (5 grains).

Tabellæ Potassii Chloratis.—Potassium chlorate, 0·3 gramme (5 grains).

Tabellæ Pulveris Ipecacuanhæ et Opii.—Powder of ipecacuanha and opium, 0·3 gramme (5 grains).

Tabellæ Quinidinæ Sulphatis.—Quinidine sulphate, 0·2 gramme (3 grains).

Tabellæ Quininæ.—Quinine sulphate, 0·06 gramme (1 grain).

Tabellæ Saccharini.—Soluble saccharin, 0·02 gramme ($\frac{1}{2}$ grain).

Tabellæ Salicini.—Salicin, 0·3 gramme (5 grains).

Tabellæ Salolis.—Salol, 0·3 gramme (5 grains).

Tabellæ Santonini.—Santonin, 0·06 gramme (1 grain), in chocolate basis.

Tabellæ Sodii Chaulmoogratis.—Sodium chaulmoograte, 0·3 gramme (5 grains).

Tabellæ Sodii Citratis.—Sodium citrate, 0·12 gramme (2 grains).

Tabellæ Sulphonalis.—Sulphonal, 0·3 gramme (5 grains).

Tabellæ Theobrominæ et Sodii Salicylatis.—Theobromine and sodium salicylate, 0·5 gramme ($7\frac{1}{2}$ grains).

TABELLÆ ACETANILIDI COMPOSITÆ

(Tab. Acetanilid. Co.)

Compound Tablets of Acetanilide

	<i>Metric</i>	<i>Imperial</i>
Acetanilide	12·96 g.	200 gr.
Caffeine	3·24 g.	50 gr.
Sodium Bicarbonate	6·48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ ACETANILIDI COMPOSITÆ CUM CODEINA

(Tab. Acetanilid. Co. c. Codein.)

Compound Tablets of Acetanilide with Codeine

	<i>Metric</i>	<i>Imperial</i>
Acetanilide	12·96 g.	200 gr.
Caffeine	3·24 g.	50 gr.
Sodium Bicarbonate	6·48 g.	100 gr.
Codeine	1·08 g.	16 $\frac{2}{3}$ gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ ACIDI ACETYLSALICYLICI COMPOSITÆ

(Tab. Acid. Acetylsalicyl. Co.)

Compound Tablets of Acetylsalicylic Acid*Synonym*—Compound Aspirin Tablets.

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid.	22·68 g.	350 gr.
Phenacetin	16·20 g.	250 gr.
Caffeine	3·24 g.	50 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.**TABELLÆ ACIDI ACETYLSALICYLICI ET CAFFEINÆ**

(Tab. Acid. Acetylsalicyl. et Caffein.)

Tablets of Acetylsalicylic Acid and Caffeine

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid.	25·92 g.	400 gr.
Caffeine	6·48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 to 3 tablets.**TABELLÆ ACIDI ACETYLSALICYLICI ET OPII**

(Tab. Acid. Acetylsalicyl. et Opii)

Tablets of Acetylsalicylic Acid and Opium*Synonym*—Tablets of Aspirin and Dover's Powder.

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid.	16·20 g.	250 gr.
Powder of Ipecacuanha and Opium	16·20 g.	250 gr.

Mix, and make into 100 tablets.

Dose.— 1 to 3 tablets.**TABELLÆ ACIDI ACETYLSALICYLICI ET OPII
COMPOSITÆ**

(Tab. Acid. Acetylsalicyl. et Opii Co.)

Compound Tablets of Acetylsalicylic Acid and Opium

	<i>Metric</i>	<i>Imperial</i>
Acetylsalicylic Acid.	19·44 g.	300 gr.
Phenacetin	8·10 g.	125 gr.
Powder of Ipecacuanha and Opium	6·48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 to 4 tablets.

TABELLÆ ALOINI COMPOSITÆ

(Tab. Aloin. Co.)

Compound Aloin Tablets

	<i>Metric</i>	<i>Imperial</i>
Aloin	1.30 g.	20 gr.
Powdered Ipecacuanha .. .	1.62 g.	25 gr.
Dry Extract of Nux Vomica ..	0.81 g.	12½ gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.**TABELLÆ BARBITONI ET AMIDOPYRINÆ**

(Tab. Barbiton. et Amidopyrin.)

Tablets of Barbitone and Amidopyrine

	<i>Metric</i>	<i>Imperial</i>
Barbitone .. .	12.96 g.	200 gr.
Amidopyrine .. .	25.92 g.	400 gr.

Mix, and make into 100 tablets.

Dose.— 1 tablet.**TABELLÆ BISMUTHI ET SODII BICARBONATIS**

(Tab. Bism. et Sod. Bicarb.)

Bismuth and Sodium Bicarbonate Tablets

	<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate .. .	12.96 g.	200 gr.
Sodium Bicarbonate .. .	19.44 g.	300 gr.

Mix, and make into 100 tablets.

Dose.— 1 to 3 tablets.**TABELLÆ FERRI CARBONATIS**

(Tab. Ferr. Carb.)

Tablets of Iron Carbonate*Synonym*—Blaud's Tablets.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Ferrous Sulphate ..	9.72 g.	150 gr.
Sucrose, in powder .. .	8.75 g.	135 gr.
Acacia, in powder .. .	1.62 g.	25 gr.
Sodium Bicarbonate .. .	9.72 g.	150 gr.
Syrup of Liquid Glucose .. .	a sufficient quantity	
Distilled Water .. .	a sufficient quantity	

Mix the exsiccated ferrous sulphate, sucrose and acacia, and granulate with a mixture of 3 parts of syrup of liquid glucose and 1 part of distilled water. Dry the granules with the aid of heat. Granulate the sodium bicarbonate with a sufficient quantity of the mixture of syrup of liquid glucose and distilled water. Dry the granules with the aid of heat, mix them with the granules previously prepared, and make into 100 tablets.

Dose.— 1 to 6 tablets.

TABELLÆ FERRI CARBONATIS ET ALOINI

(Tab. Ferr. Carb. et Aloin.)

Tablets of Iron Carbonate and Aloin

Synonym—Blaud's Tablets with Aloin.

	<i>Metric</i>	<i>Imperial</i>
Exsiccated Ferrous Sulphate ..	9.72 g.	150 gr.
Sucrose, in powder	8.75 g.	135 gr.
Acacia, in powder	1.62 g.	25 gr.
Sodium Bicarbonate	9.72 g.	150 gr.
Aloin	0.32 g.	5 gr.
Syrup of Liquid Glucose ..	a sufficient quantity	
Distilled Water	a sufficient quantity	

Mix the exsiccated ferrous sulphate, sucrose and acacia, and granulate with a mixture of 3 parts of syrup of liquid glucose and 1 part of distilled water. Dry the granules with the aid of heat. Granulate the sodium bicarbonate with a sufficient quantity of the mixture of syrup of liquid glucose and distilled water. Dry the granules with the aid of heat, mix them with the granules previously prepared and with the aloin, and make into 100 tablets.

Dose.— 1 to 6 tablets.

TABELLÆ FERRI PHOSPHATIS CUM QUININA ET STRYCHNINA

(Tab. Ferr. Phosph. c. Quinin. et Strych.)

Tablets of Ferrous Phosphate with Quinine and Strychnine

Synonyms—Tabellæ Trium Phosphatum; Easton's Tablets; Tabellæ Eastonii; Tabellæ Ferri et Quininæ et Strychninæ Phosphatum.

	<i>Metric</i>	<i>Imperial</i>
Saccharated Iron Phosphate ..	15.23 g.	235 gr.
Strychnine Hydrochloride ..	0.10 g.	1½ gr.
Quinine Sulphate	5.18 g.	80 gr.
Sucrose, in powder	5.18 g.	80 gr.
Potato Starch, in powder ..	1.30 g.	20 gr.
Purified Talc	0.97 g.	15 gr.
Distilled Water	a sufficient quantity	

Triturate the strychnine with the sucrose, and mix it intimately with the quinine sulphate and saccharated iron phosphate, pass the mixed powder through a fine sieve, granulate with the distilled water, dry the granules, mix with the starch and talc, and make into 100 tablets.

Dose.—1 tablet.

TABELLÆ FORMALDEHYDI

(Tab. Formaldehyd.)

Tablets of Formaldehyde

Synonyms—Formaldehyde and Menthol Tablets; Formalin Throat Tablets; Formamint Tablets.

			<i>Metric</i>	<i>Imperial</i>
Paraformaldehyde	0.97 g.	15 gr.
Menthol	0.26 g.	4 gr.
Citric Acid	1.94 g.	30 gr.
Terpeneless Oil of Lemon	0.03 ml.	$\frac{1}{2}$ m.
Acacia, in powder	9.72 g.	150 gr.
Sucrose, in powder	87.08 g.	3 oz. 30 gr.

Mix, and make into 100 tablets.

Dose.—1 or 2 tablets.

Note.—The general use of the names "Formalin" and "Formamint" for tablets of formaldehyde is limited to Great Britain and Northern Ireland.

TABELLÆ GUAIACI ET SULPHURIS

(Tab. Guaiac. et Sulphur.)

Tablets of Guaiacum and Sulphur

			<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin, in powder	19.44 g.	300 gr.
Sublimed Sulphur	19.44 g.	300 gr.

Mix, and make into 100 tablets.

Dose.—1 to 3 tablets.

TABELLÆ HYPOPHOSPHITUM COMPOSITÆ

(Tab. Hypophosph. Co.)

Compound Tablets of Hypophosphites

			<i>Metric</i>	<i>Imperial</i>
Calcium Hypophosphite	3.24 g.	50 gr.
Manganese Hypophosphite	1.62 g.	25 gr.
Potassium Hypophosphite	1.62 g.	25 gr.
Iron Hypophosphite	1.62 g.	25 gr.
Quinine Hypophosphite	0.81 g.	12 $\frac{1}{2}$ gr.
Strychnine	0.04 g.	$\frac{1}{2}$ gr.
Potato Starch, in powder	12.5 g.	200 gr.
Sucrose, in powder	to 22.68 g.	to 350 gr.

Mix the hypophosphites of calcium, manganese and potassium with the strychnine, and grind well together in a mortar. Dissolve the iron hypophosphite in a little water, granulate the mixed powders with the solution, and dry the granules. Pass the dried granules, together with the starch, through a sieve, and make up to the required weight with sucrose. Make into 100 sugar-coated tablets.

Dose.— 1 or 2 tablets.

TABELLÆ LEPTANDRÆ COMPOSITÆ

(Tab. Leptand. Co.)

Compound Tablets of Leptandra

Synonyms—Tabellæ Laxativæ Compositæ; Vegetable Laxative Tablets.

	<i>Metric</i>	<i>Imperial</i>
Compound Extract of Colocynth	6.48 g.	100 gr.
Jalap Resin, in powder	1.62 g.	25 gr.
Resin of Podophyllum, in powder	1.62 g.	25 gr.
Extract of Leptandra	1.62 g.	25 gr.
Dry Extract of Hyoscyamus . . .	1.62 g.	25 gr.
Extract of Taraxacum	1.62 g.	25 gr.
Oil of Peppermint	0.59 ml.	10 m.

Mix, and make into 100 tablets.

Dose.— 1 to 3 tablets.

TABELLÆ PANCREATINI

(Tab. Pancreatin.)

Pancreatin Tablets

Synonym—Peptonising Tablets.

	<i>Metric</i>	<i>Imperial</i>
Pancreatin	16.2 g.	250 gr.
Sodium Bicarbonate	64.8 g.	2 oz. 125 gr.
Sucrose, in powder	16.2 g.	250 gr.
Distilled Water	a sufficient quantity	

Mix, and make into 100 tablets.

TABELLÆ PARATHYROIDEI ET CALCII LACTATIS

(Tab. Parathyroid. et Calc. Lact.)

Tablets of Parathyroid and Calcium Lactate

	<i>Metric</i>	<i>Imperial</i>
Parathyroid	0.16 g.	2½ gr.
Calcium Lactate	32.40 g.	1 oz. 62½ gr.

Mix, and make into 100 tablets.

Dose.— 1 to 4 tablets.

TABELLÆ PARATHYROIDEI ET CALCII ET SODII LACTATIS

(Tab. Parathyroid. et Calc. et Sod. Lact.)

Tablets of Parathyroid and Calcium Sodium Lactate

	<i>Metric</i>	<i>Imperial</i>
Parathyroid	0.16 g.	2½ gr.
Calcium Sodium Lactate ..	48.60 g.	1 oz. 312½ gr.

Mix, and make into 100 tablets.

Dose.— 1 to 4 tablets.

TABELLÆ PHENACETINI COMPOSITÆ

(Tab. Phenacet. Co.)

Compound Phenacetin Tablets

	<i>Metric</i>	<i>Imperial</i>
Phenacetin	25.92 g.	400 gr.
Caffeine	6.48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ PHENACETINI ET CAFFEINÆ CITRATIS

(Tab. Phenacet. et Caffein. Cit.)

Tablets of Phenacetin and Caffeine Citrate

	<i>Metric</i>	<i>Imperial</i>
Phenacetin	25.92 g.	400 gr.
Caffeine Citrate	6.48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ PHENOBARBITONI ET THEOBROMINÆ

(Tab. Phenobarbiton. et Theobrom.)

Tablets of Phenobarbitone and Theobromine

	<i>Metric</i>	<i>Imperial</i>
Phenobarbitone	3.24 g.	50 gr.
Theobromine	32.40 g.	1 oz. 62½ gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ PHENOLPHTHALEINI COMPOSITÆ

(Tab. Phenolphthal. Co.)

Compound Phenolphthalein Tablets

	<i>Metric</i>	<i>Imperial</i>
Phenolphthalein	6.48 g.	100 gr.
Dry Extract of Belladonna ..	0.065 g.	1 gr.
Strychnine Sulphate	0.013 g.	$\frac{1}{8}$ gr.

Mix, and make into 100 tablets.

Dose.— 1 to 3 tablets.**TABELLÆ PHOSPHATUM ET HYPOPHOSPHITUM COMPOSITÆ**

(Tab. Phosph. et Hypophosph. Co.)

Compound Tablets of Phosphates and Hypophosphites*Synonym*—Triple Syrup Tablets.

	<i>Metric</i>	<i>Imperial</i>
Saccharated Iron Phosphate ..	7.58 g.	117 gr.
Calcium Phosphate	1.94 g.	30 gr.
Potassium Phosphate	0.13 g.	2 gr.
Sodium Phosphate	0.13 g.	2 gr.
Calcium Hypophosphite	1.10 g.	17 gr.
Manganese Hypophosphite ..	0.55 g.	$8\frac{1}{2}$ gr.
Potassium Hypophosphite ..	0.55 g.	$8\frac{1}{2}$ gr.
Iron Hypophosphite	0.55 g.	$8\frac{1}{2}$ gr.
Strychnine	0.049 g.	$\frac{3}{4}$ gr.
Quinine Sulphate	2.00 g.	31 gr.
Potato Starch, in powder ..	to 19.44 g.	to 300 gr.

Mix, and make into 100 sugar-coated tablets.

Dose.— 1 tablet.**TABELLÆ PLUMBI CUM OPIO**

(Tab. Plumb. c. Opio)

Tablets of Lead with Opium

	<i>Metric</i>	<i>Imperial</i>
Lead Acetate	19.44 g.	300 gr.
Powdered Opium, in fine powder	3.24 g.	50 gr.
Sucrose, in powder	6.48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 tablet.

TABELLÆ POTASSII CHLORATIS ET BORACIS

(Tab. Pot. Chlorat. et Borac.)

Tablets of Potassium Chlorate and Borax

		<i>Metric</i>	<i>Imperial</i>
Potassium Chlorate	19.44 g.	300 gr.
Borax	12.96 g.	200 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.**TABELLÆ RHEI ET SODII BICARBONATIS**

(Tab. Rhei et Sod. Bicarb.)

Tablets of Rhubarb and Sodium Bicarbonate*Synonym*—Rhubarb and Soda Tablets.

		<i>Metric</i>	<i>Imperial</i>
Rhubarb, in powder	19.44 g.	300 gr.
Sodium Bicarbonate	9.72 g.	150 gr.
Ginger, in powder	3.24 g.	50 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.**TABELLÆ SANTONINI ET HYDRARGYRI SUBCHLORIDI**

(Tab. Santonin. et Hydrarg. Subchlor.)

Tablets of Santonin and Mercurous Chloride*Synonyms*—Compound Santonin Tablets; Santonin and Calomel Tablets; Tabellæ Santonini Compositæ.

		<i>Metric</i>	<i>Imperial</i>
Santonin	6.48 g.	100 gr.
Mercurous Chloride	6.48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.**TABELLÆ SANTONINI ET SCAMMONIÆ COMPOSITÆ**

(Tab. Santonin. et Scammon. Co.)

Compound Tablets of Santonin and Scammony

		<i>Metric</i>	<i>Imperial</i>
Santonin	9.72 g.	150 gr.
Compound Powder of Scammony	12.96 g.	200 gr.
Mercurous Chloride	3.24 g.	50 gr.

Mix, and make into 100 tablets.

Dose.— 1 tablet.

TABELLÆ SODII BICARBONATIS COMPOSITÆ

(Tab. Sod. Bicarb. Co.)

Compound Tablets of Sodium Bicarbonate*Synonym*—Soda Mint Tablets.

		<i>Metric</i>	<i>Imperial</i>
Sodium Bicarbonate	32.40 g.	1 oz. 62½ gr.
Ammonium Bicarbonate	0.81 g.	12½ gr.
Saccharin	0.13 g.	2 gr.
Oil of Peppermint	0.74 ml.	12½ m.

Granulate the sodium bicarbonate, saccharin and oil of peppermint mix with the ammonium bicarbonate, and make into 100 tablets.

Dose.— 1 to 4 tablets.

TABELLÆ SODII NITRITIS COMPOSITÆ

(Tab. Sod. Nitrit. Co.)

Compound Tablets of Sodium Nitrite

		<i>Metric</i>	<i>Imperial</i>
Sodium Nitrite	3.24 g.	50 gr.
Diluted Erythrityl Tetranitrate	2.16 g.	33½ gr.
Ammonium Hippurate	6.48 g.	100 gr.

Mix, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TABELLÆ ZINGIBERIS COMPOSITÆ

(Tab. Zingib. Co.)

Compound Tablets of Ginger*Synonym*—Ginger Mint Tablets.

		<i>Metric</i>	<i>Imperial</i>
Oleoresin of Ginger	0.16 g.	2½ gr.
Sodium Bicarbonate	32.40 g.	1 oz. 62½ gr.
Ammonium Bicarbonate	0.81 g.	12½ gr.
Saccharin	0.13 g.	2 gr.
Oil of Peppermint	0.74 ml.	12½ m.

Granulate the oleoresin of ginger, sodium bicarbonate, saccharin and oil of peppermint, add the ammonium bicarbonate, and make into 100 tablets.

Dose.— 1 or 2 tablets.

TEREBINTHINA VENETA FACTITIA

(Tereb. Venet. Fact.)

Factitious Venice Turpentine

			<i>Metric</i>	<i>Imperial</i>
Colophony	625 g.	10 oz.
Linseed Oil	225 g.	3 oz. 262½ gr.
Oil of Turpentine	150 g.	2 oz. 175 gr.

Melt together the colophony and the linseed oil, remove from the source of heat, and stir in the oil of turpentine.

TINCTURÆ

Tinctures

Tinctures are usually alcoholic liquids containing, in comparatively dilute solution, the active principles of vegetable drugs. They are frequently prepared by maceration or by percolation; in other cases they are obtained by dilution of the corresponding liquid extract. The processes of maceration and of percolation to be used in the preparation of tinctures are those described in the British Pharmacopœia. The alcohol content of tinctures is determined by an appropriate method as described in the British Pharmacopœia.

TINCTURA ABSINTHII

(Tinct. Absinth.)

Tincture of Absinthium

			<i>Metric</i>	<i>Imperial</i>
Absinthium	100 g.	2 oz.
Alcohol (70 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.— 4 to 16 millilitres (1 to 4 fluid drachms).

Alcohol content, 65 to 69 per cent. v/v of ethyl alcohol.

TINCTURA ACONITI

(Tinct. Aconit.)

Tincture of Aconite

	<i>Metric</i>	<i>Imperial</i>
Aconite, in moderately fine powder	150 g.	3 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—0·12 to 0·3 millilitre (2 to 5 minims).

Alcohol content, 67 to 69 per cent. v/v of ethyl alcohol.

TINCTURA ACONITI FORTIS

(Tinct. Aconit. Fort.)

Strong Tincture of Aconite

Synonym—Fleming's Tincture of Aconite.

	<i>Metric</i>	<i>Imperial</i>
Aconite, in moderately fine powder	700 g.	14 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Alcohol content, 64 to 67 per cent. v/v of ethyl alcohol.

TINCTURA ALOES

(Tinct. Aloes)

Tincture of Aloes

	<i>Metric</i>	<i>Imperial</i>
Aloes, crushed	25 g.	$\frac{1}{2}$ oz.
Liquid Extract of Liquorice ..	150 ml.	3 fl. oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Place the aloes in a closed vessel with 800 millilitres (16 fluid ounces) of the alcohol; set aside for forty-eight hours, occasionally shaking until dissolved; add the liquid extract of liquorice, filter, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.—2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Alcohol content, 38 to 42 per cent. v/v of ethyl alcohol.

TINCTURA ALOES COMPOSITA

(Tinct. Aloes Co.)

Compound Tincture of Aloes

	<i>Metric</i>	<i>Imperial</i>
Aloes, crushed	30 g.	262½ gr.
Gentian, cut small and bruised..	5 g.	43¾ gr.
Rhubarb, in moderately coarse powder	5 g.	43¾ gr.
Ginger, in moderately coarse powder	5 g.	43¾ gr.
Alcohol (70 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 64 to 68 per cent. v/v of ethyl alcohol.

TINCTURA ALOES ET MYRRHÆ

(Tinct. Aloes et Myrrh.)

Tincture of Aloes and Myrrh*Synonym*—Elixir Proprietatis.

	<i>Metric</i>	<i>Imperial</i>
Aloes, crushed	100 g.	2 oz.
Saffron	50 g.	1 oz.
Tincture of Myrrh	1000 ml.	20 fl. oz.

Macerate for seven days, with frequent agitation, and strain.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 76 to 79 per cent. v/v of ethyl alcohol.

TINCTURA AMMONIÆ COMPOSITA

(Tinct. Ammon. Co.)

Compound Tincture of Ammonia*Synonym*—Eau de Luce.

	<i>Metric</i>	<i>Imperial</i>
Mastic	12.5 g.	½ oz.
Alcohol (90 per cent.)	55.0 ml.	1 fl. oz. 48 m.
Oil of Lavender	1.5 ml.	15 m.
Strong Solution of Ammonia ..	to 1000.0 ml.	to 20 fl. oz.

Dissolve the mastic in a mixture of the alcohol and 900 millilitres (18 fluid ounces) of strong solution of ammonia, filter if necessary, and add the oil of lavender and sufficient strong solution of ammonia to produce the required volume.

Alcohol content, 4 to 6 per cent. v/v of ethyl alcohol.

TINCTURA ANTIPERIODICA

(Tinct. Antiperiod.)

Antiperiodic Tincture*Synonym*—Warburg's Tincture.

	<i>Metric</i>	<i>Imperial</i>
Aloes, crushed	27·4 g.	240 gr.
Rhubarb, bruised	9·1 g.	80 gr.
Angelica Fruit, bruised	9·1 g.	80 gr.
Elecampane, bruised	4·6 g.	40 gr.
Saffron	4·6 g.	40 gr.
Fennel, bruised	4·6 g.	40 gr.
Chalk	4·6 g.	40 gr.
Gentian, bruised	2·3 g.	20 gr.
Zedoary, bruised	2·3 g.	20 gr.
Cubeb, bruised	2·3 g.	20 gr.
Myrrh, crushed	2·3 g.	20 gr.
Agaric, in powder	2·3 g.	20 gr.
Powdered Opium	0·3 g.	2½ gr.
Black Pepper, bruised	0·5 g.	4½ gr.
Cinnamon, bruised	0·9 g.	8 gr.
Ginger, bruised	0·9 g.	8 gr.
Quinine Sulphate	20·0 g.	175 gr.
Camphor	2·3 g.	20 gr.
Alcohol (60 per cent.)	to 1000·0 ml.	to 20 fl. oz.

Macerate all the ingredients, except the quinine sulphate and the camphor, with 1000 millilitres (20 fluid ounces) of the alcohol for seven days; then press, filter, dissolve the quinine sulphate and the camphor in the filtrate, set aside for three days, again filter, and add sufficient of the alcohol to produce the required volume.

Dose. 4 to 16 millilitres (1 to 4 fluid drachms).

Alcohol content, 53 to 57 per cent. v/v of ethyl alcohol.

TINCTURA APOCYNII

(Tinct. Apocyn.)

Tincture of Apocynum*Synonym*—Tincture of Canadian Hemp.

	<i>Metric</i>	<i>Imperial</i>
Apocynum, in moderately fine powder	100 g.	2 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose. 0·3 to 0·6 millilitre (5 to 10 minims).

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

TINCTURA ARNICÆ FLORIS

(Tinct. Arnicae Flor.)

Tincture of Arnica Flower

	<i>Metric</i>	<i>Imperial</i>
Arnica Flower, in moderately coarse powder	100 g.	2 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 43 to 45 per cent. v/v of ethyl alcohol.

TINCTURA ARNICÆ RADICIS

(Tinct. Arnicae Rad.)

Tincture of Arnica Root*Synonym*—Tincture of Arnica.

	<i>Metric</i>	<i>Imperial</i>
Arnica Root, in moderately fine powder	50 g.	1 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Alcohol content, 66 to 69 per cent. v/v of ethyl alcohol.

TINCTURA BAPTISIÆ

(Tinct. Baptisiae)

Tincture of Baptisia

	<i>Metric</i>	<i>Imperial</i>
Baptisia, in moderately coarse powder	100 g.	2 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA BENZOINI

(Tinct. Benzoin.)

Tincture of Benzoin*Synonym*—Simple Tincture of Benzoin.

	<i>Metric</i>	<i>Imperial</i>
Benzoin, crushed.. ..	100 g.	2 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Macerate the benzoin in 800 millilitres (16 fluid ounces) of the alcohol for one hour, with frequent agitation; then filter, and pass sufficient alcohol through the filter to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 82 to 85 per cent. v/v of ethyl alcohol.

TINCTURA BERBERIDIS

(Tinct. Berber.)

Tincture of Berberis

	<i>Metric</i>	<i>Imperial</i>
Berberis, in moderately fine powder	100 g.	2 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA BOLDO

(Tinct. Boldo)

Tincture of Boldo

	<i>Metric</i>	<i>Imperial</i>
Boldo, in moderately coarse powder.. ..	100 g.	2 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—0.6 to 2 millilitres (10 to 30 minims).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA BRYONIÆ

(Tinct. Bryon.)

Tincture of Bryony

	<i>Metric</i>	<i>Imperial</i>
Bryony, dried and bruised ..	100 g.	2 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.— 0·06 to 0·6 millilitre (1 to 10 minims).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA BUCHU

(Tinct. Buchu)

Tincture of Buchu

	<i>Metric</i>	<i>Imperial</i>
Buchu, in moderately coarse powder.. ..	200 g.	4 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA CALENDULÆ

(Tinct. Calend.)

Tincture of Calendula

	<i>Metric</i>	<i>Imperial</i>
Calendula, in coarse powder ..	200 g.	4 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Alcohol content, 85 to 88 per cent. v/v of ethyl alcohol.

TINCTURA CANNABIS

(Tinct. Cannab.)

Tincture of Cannabis

	<i>Metric</i>	<i>Imperial</i>
Extract of Cannabis	50 g.	1 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

Alcohol content, 83 to 87 per cent. v/v of ethyl alcohol.

TINCTURA CAPSICI FORTIOR

(Tinct. Capsic. Fort.)

Stronger Tincture of Capsicum*Synonym*—Turnbull's Tincture of Capsicum.

	<i>Metric</i>	<i>Imperial</i>
Capsicum, in moderately coarse powder	333 g.	6 oz. 288 $\frac{3}{4}$ gr.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—0·06 to 0·2 millilitre (1 to 3 minims).

Alcohol content, 54 to 58 per cent. v/v of ethyl alcohol.

TINCTURA CARDAMOMI AROMATICA

(Tinct. Cardam. Aromat.)

Aromatic Tincture of Cardamom*Synonyms*—Tinctura Carminativa; Carminative Tincture.

	<i>Metric</i>	<i>Imperial</i>
Cardamom, bruised	68·5 g.	1 oz. 162 $\frac{1}{2}$ gr.
Strong Tincture of Ginger	62·5 ml.	1 $\frac{1}{4}$ fl. oz.
Oil of Caraway	10·4 ml.	100 m.
Oil of Cinnamon	10·4 ml.	100 m.
Oil of Clove	10·4 ml.	100 m.
Alcohol (90 per cent.)	to 1000·0 ml.	to 20 fl. oz.

Macerate the cardamom in 750 millilitres (15 fluid ounces) of the alcohol for seven days, strain, and press the marc. Dissolve the oils in the mixed tinctures, and add sufficient alcohol to produce the required volume.

Dose.—0·12 to 0·6 millilitre (2 to 10 minims).

Alcohol content, 84 to 88 per cent. v/v of ethyl alcohol.

TINCTURA CASCARILLÆ

(Tinct. Cascaril.)

Tincture of Cascarilla

	<i>Metric</i>	<i>Imperial</i>
Cascarilla, in moderately fine powder	200 g.	4 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 64 to 67 per cent. v/v of ethyl alcohol.

TINCTURA CASTOREI

(Tinct. Castor.)

Tincture of Castor

	<i>Metric</i>	<i>Imperial</i>
Castor, coarsely powdered	50 g.	1 oz.
Alcohol (90 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 86 to 89 per cent. v/v of ethyl alcohol.

TINCTURA CEREI

(Tinct. Cerei)

Tincture of Cereus*Synonym*—Tinctura Cacti Grandiflori.

	<i>Metric</i>	<i>Imperial</i>
Cereus, in coarse powder	250 g.	5 oz.
Alcohol (90 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—0.12 to 2 millilitres (2 to 30 minims).

Alcohol content, 84 to 89 per cent. v/v of ethyl alcohol.

TINCTURA CHIRATÆ

(Tinct. Chirat.)

Tincture of Chiretta

	<i>Metric</i>	<i>Imperial</i>
Chiretta, in moderately fine powder	100 g.	2 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 54 to 58 per cent. v/v of ethyl alcohol.

TINCTURA CHLOROFORMI COMPOSITA

(Tinct. Chlorof. Co.)

Compound Tincture of Chloroform

	<i>Metric</i>	<i>Imperial</i>
Chloroform	100 ml.	2 fl. oz.
Alcohol (90 per cent.)	400 ml.	8 fl. oz.
Compound Tincture of Cardamom	100 ml.	10 fl. oz.

Mix.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Alcohol content, 62 to 65 per cent. v/v of ethyl alcohol.

TINCTURA CHLOROFORMI ET MORPHINÆ

(Tinct. Chlorof. et Morph.)

Tincture of Chloroform and Morphine*Synonyms*—Chlorodyne; 'Tinct. Chlorof. et Morph., B.P. '85.

	<i>Metric</i>	<i>Imperial</i>
Chloroform	125.00 ml.	2½ fl. oz.
Ether	31.25 ml.	300 m.
Alcohol (90 per cent.)	125.00 ml.	2½ fl. oz.
Morphine Hydrochloride	2.29 g.	20 gr.
Dilute Hydrocyanic Acid	62.50 ml.	1¼ fl. oz.
Oil of Peppermint	1.04 ml.	10 m.
Liquid Extract of Liquorice	125.00 ml.	2½ fl. oz.
Treacle	125.00 ml.	2½ fl. oz.
Syrup	to 1000.00 ml.	to 20 fl. oz.

Dissolve the morphine hydrochloride and the oil of peppermint in the alcohol (90 per cent.), and add the chloroform and ether. Mix the liquid extract of liquorice and treacle with 400 millilitres (8 fluid ounces) of syrup, add this to the previously formed solution, mix them thoroughly, add the hydrocyanic acid and sufficient syrup to produce the required volume.

Dose.—0.3 to 0.6 millilitre (5 to 10 minims).

Alcohol content, 12 to 15 per cent. v/v of ethyl alcohol.

TINCTURA CHLOROFORMI ET MORPHINÆ COMPOSITA

(Tinct. Chlorof. et Morph. Co.)

Compound Tincture of Chloroform and Morphine

	<i>Metric</i>	<i>Imperial</i>
Chloroform	75 ml.	1½ fl. oz.
Morphine Hydrochloride	10 g.	87½ gr.
Dilute Hydrocyanic Acid	50 ml.	1 fl. oz.
Tincture of Capsicum	25 ml.	½ fl. oz.
Tincture of Cannabis	100 ml.	2 fl. oz.
Oil of Peppermint	2 ml.	19 m.
Glycerin	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the chloroform, tincture of capsicum, tincture of cannabis, oil of peppermint and glycerin with 450 millilitres (9 fluid ounces) of the alcohol, and dissolve the morphine hydrochloride in the mixture; add the dilute hydrocyanic acid and sufficient alcohol to produce the required volume.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

Alcohol content, 52 to 56 per cent. v/v of ethyl alcohol.

TINCTURA CIMICIFUGÆ

(Tinct. Cimicif.)

Tincture of Cimicifuga*Synonym*—Tincture of *Actæa Racemosa*.

	<i>Metric</i>	<i>Imperial</i>
Cimicifuga, in moderately coarse powder	100 g.	2 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA CINNAMOMI

(Tinct. Cinnam.)

Tincture of Cinnamon

	<i>Metric</i>	<i>Imperial</i>
Cinnamon, in moderately fine powder	200 g.	4 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 65 to 69 per cent. v/v of ethyl alcohol.

TINCTURA CINNAMOMI COMPOSITA

(Tinct. Cinnam. Co.)

Compound Tincture of Cinnamon

	<i>Metric</i>	<i>Imperial</i>
Cinnamon, bruised	25.0 g.	$\frac{1}{2}$ oz.
Cardamom, bruised	12.5 g.	$\frac{1}{4}$ oz.
Long Pepper, bruised	10.0 g.	87 $\frac{1}{2}$ gr.
Ginger, bruised	10.0 g.	87 $\frac{1}{2}$ gr.
Alcohol (60 per cent.)	1000.0 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA COLLINSONIÆ

(Tinct. Collinson.)

Tincture of Collinsonia

	<i>Metric</i>	<i>Imperial</i>
Collinsonia, in moderately coarse powder	100 g.	2 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.— 2 to 8 millilitres ($\frac{1}{2}$ to 2 fluid drachms).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA CONVALLARIÆ

(Tinct. Convallar.)

Tincture of Convallaria

	<i>Metric</i>	<i>Imperial</i>
Convallaria, in moderately coarse powder	125 g.	2½ oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 0·3 to 1·2 millilitres (5 to 20 minims).

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

TINCTURA COTO

(Tinct. Coto)

Tincture of Coto

	<i>Metric</i>	<i>Imperial</i>
Coto, bruised	100 g.	2 oz.
Alcohol (90 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.— 0·6 to 2 millilitres (10 to 30 minims).

Alcohol content, 86 to 89 per cent. v/v of ethyl alcohol.

TINCTURA CUBEBAE

(Tinct. Cubeb.)

Tincture of Cubebs

	<i>Metric</i>	<i>Imperial</i>
Cubeb, in moderately coarse powder	200 g.	4 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 83 to 87 per cent. v/v of ethyl alcohol.

TINCTURA ERGOTÆ AMMONIATA

(Tinct. Ergot. Ammon.)

Ammoniated Tincture of Ergot

	<i>Metric</i>	<i>Imperial</i>
Ergot, in moderately coarse powder	250 g.	5 oz.
Dilute Solution of Ammonia	100 ml.	2 fl. oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the dilute solution of ammonia with 900 millilitres (18 fluid ounces) of the alcohol, moisten the ergot with 100 millilitres (2 fluid ounces) of this mixture, and percolate with the remainder; press the marc, mix the expressed liquid with the percolate, and add sufficient of the alcohol to produce the required volume; set aside for twenty-four hours, and filter.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 51 to 54 per cent. v/v of ethyl alcohol.

TINCTURA EUCALYPTI

(Tinct. Eucalyp.)

Tincture of Eucalyptus

	<i>Metric</i>	<i>Imperial</i>
Eucalyptus, in moderately coarse powder	200 g.	4 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 1 to 8 millilitres ($\frac{1}{4}$ to 2 fluid drachms).

Alcohol content, 53 to 58 per cent. v/v of ethyl alcohol.

TINCTURA EUONYMI

(Tinct. Euonym.)

Tincture of Euonymus

	<i>Metric</i>	<i>Imperial</i>
Euonymus, in moderately coarse powder	200 g.	4 oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 0·6 to 2·6 millilitres (10 to 40 minims).

Alcohol content, 41 to 44 per cent. v/v of ethyl alcohol.

TINCTURA FERRI PERCHLORIDI

(Tinct. Ferr. Perchlor.)

Tincture of Ferric Chloride

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Ferric Chloride	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	250 ml.	5 fl. oz.
Distilled Water	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.— 0·3 to 1 millilitre (5 to 15 minims).

Alcohol content, 22 to 24 per cent. v/v of ethyl alcohol.

TINCTURA GALLÆ

(Tinct. Gall.)

Tincture of Gall

	<i>Metric</i>	<i>Imperial</i>
Gall, in moderately fine powder	125 g.	2½ oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 2 to 8 millilitres (½ to 2 fluid drachms).

Alcohol content, 53 to 57 per cent. v/v of ethyl alcohol.

TINCTURA GELSEMII

(Tinct. Gelsem.)

Tincture of Gelsemium

	<i>Metric</i>	<i>Imperial</i>
Gelsemium, in moderately fine powder	100 g.	2 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—0·3 to 1 millilitre (5 to 15 minims).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA GOSSYPII CORTICIS

(Tinct. Gossyp. Cort.)

Tincture of Cotton Root Bark

	<i>Metric</i>	<i>Imperial</i>
Cotton Root Bark, in moderately coarse powder	250 g.	5 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 54 to 58 per cent. v/v of ethyl alcohol.

TINCTURA GUAIACI

(Tinct. Guaiac.)

Tincture of Guaiacum

Synonym—Tincture of Guaiac.

	<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin, in powder	200 g.	4 oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Macerate the guaiacum resin with 850 millilitres (17 fluid ounces) of the alcohol for forty-eight hours in a closed vessel, shaking frequently; then filter, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 74 to 78 per cent. v/v of ethyl alcohol.

TINCTURA GUAIACI AMMONIATA

(Tinct. Guaiac. Ammon.)

Ammoniated Tincture of Guaiacum

	<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin, in powder	200 g.	4 oz.
Oil of Nutmeg	3 ml.	29 m.
Oil of Lemon	2 ml.	19 m.
Strong Solution of Ammonia	75 ml.	1½ fl. oz.
Alcohol (90 per cent.) to 1000 ml.		to 20 fl. oz.

Mix the strong solution of ammonia with 700 millilitres (14 fluid ounces) of the alcohol, add the guaiacum resin, and set aside in a closed vessel for forty-eight hours, shaking occasionally; filter, dissolve the oil of lemon and oil of nutmeg in the filtrate, and pour sufficient of the alcohol through the filter to produce the required volume.

Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Alcohol content, 65 to 71 per cent. v/v of ethyl alcohol.

TINCTURA GUARANÆ

(Tinct. Guaran.)

Tincture of Guarana

	<i>Metric</i>	<i>Imperial</i>
Guarana, in powder	250 g.	5 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 54 to 58 per cent. v/v of ethyl alcohol.

TINCTURA HAMAMELIDIS

(Tinct. Hamam.)

Tincture of Hamamelis

	<i>Metric</i>	<i>Imperial</i>
Hamamelis Bark, in moderately coarse powder	100 g.	2 oz.
Alcohol (45 per cent.) to 1000 ml.		to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres (½ to 1 fluid drachm).

Alcohol content, 41 to 44 per cent. v/v of ethyl alcohol.

TINCTURA HYDRASTIS

(Tinct. Hydrast.)

Tincture of Hydrastis*Synonym*—Tinctura Hydrastidis I.A.

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Hydrastis ..	100 ml.	2 fl. oz.
Alcohol (60 per cent.) to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA IGNATIÆ

(Tinct. Ignat.)

Tincture of Ignatia

	<i>Metric</i>	<i>Imperial</i>
Ignatia, in moderately coarse powder		
	100 g.	2 oz.
Alcohol (90 per cent.) to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—0.3 to 1.2 millilitres (5 to 20 minims).

Alcohol content, 86 to 89 per cent. v/v of ethyl alcohol.

TINCTURA JABORANDI

(Tinct. Jaborand.)

Tincture of Jaborandi

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Jaborandi ..	200 ml.	4 fl. oz.
Alcohol (45 per cent.) to 1000 ml.	to 20 fl. oz.
Mix.		

Dose.—0.6 to 2 millilitres (10 to 30 minims).

Alcohol content, 41 to 44 per cent. v/v of ethyl alcohol.

TINCTURA JALAPÆ

(Tinct. Jalap.)

Tincture of Jalap

	<i>Metric</i>	<i>Imperial</i>
Jalap, in moderately fine powder	200 g.	4 oz.
Alcohol (70 per cent.)	a sufficient quantity

Moisten the jalap with a sufficient quantity of the alcohol, pack in a percolator, and gradually add more of the alcohol until 600 millilitres (12 fluid ounces) of percolate has been collected; press the marc, add the expressed liquid to the percolate, set aside for twenty-four hours, and filter. Determine the proportion of resin in the tincture thus prepared, using 60 millilitres, and dilute the remainder with sufficient of the alcohol to produce a tincture of the required strength.

Standard.—Tincture of jalap, determined by the method of the British Pharmacopœia for Jalapa, commencing with the words “remove most of the alcohol . . .” and using 100 millilitres, contains not less than 1·45 per cent. and not more than 1·55 per cent. w/v of resin.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 65 to 68 per cent. v/v of ethyl alcohol.

TINCTURA JALAPÆ COMPOSITA

(Tinct. Jalap. Co.)

Compound Tincture of Jalap

	<i>Metric</i>	<i>Imperial</i>
Jalap, in moderately fine powder	80 g.	1 oz. 262½ gr.
Scammony Resin, in powder ..	15 g.	131¼ gr.
Turpeth, in moderately fine powder	10 g.	87½ gr.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

TINCTURA KINO

(Tinct. Kino)

Tincture of Kino

	<i>Metric</i>	<i>Imperial</i>
Kino, in powder	100 g.	2 oz.
Glycerin	150 ml.	3 fl. oz.
Distilled Water	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix the glycerin and the distilled water, and triturate the kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder; transfer to a closed vessel, add 500 millilitres (10 fluid ounces) of the alcohol, and set aside for twelve hours, shaking occasionally; then filter, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 44 to 48 per cent. v/v of ethyl alcohol.

TINCTURA KINO EUCALYPTI

(Tinct. Kino Eucalyp.)

Tincture of Eucalyptus Kino*Synonyms*—Tinctura Gummi Rubri; Tincture of Red Gum.

	<i>Metric</i>	<i>Imperial</i>
Eucalyptus Kino, in powder ..	250 g.	5 oz.
Alcohol (45 per cent.) to 1000 ml.	to 20 fl. oz.

Macerate the eucalyptus kino with 1000 millilitres (20 fluid ounces) of the alcohol for forty-eight hours, with frequent agitation; then strain, and add sufficient of the alcohol to produce the required volume.

Dose.—1 to 2·6 millilitres (15 to 40 minims).

Alcohol content, 34 to 38 per cent. v/v of ethyl alcohol.

TINCTURA KOLÆ

(Tinct. Kola)

Tincture of Kola

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Kola ..	200 ml.	4 fl. oz.
Alcohol (60 per cent.) to 1000 ml.	to 20 fl. oz.

Mix.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA LAVANDULÆ COMPOSITA

(Tinct. Lavand. Co.)

Compound Tincture of Lavender

	<i>Metric</i>	<i>Imperial</i>
Oil of Lavender	5·0 ml.	48 m.
Oil of Rosemary	0·5 ml.	5 m.
Cinnamon, bruised	10·0 g.	87½ gr.
Nutmeg, bruised	10·0 g.	87½ gr.
Red Sanders Wood, rasped ..	20·0 g.	175 gr.
Alcohol (90 per cent.) ..	to 1000·0 ml.	to 20 fl. oz.

Macerate the oil of lavender, oil of rosemary, cinnamon, nutmeg and red sanders wood with 900 millilitres (18 fluid ounces) of the

alcohol in a closed vessel for seven days, shaking occasionally; filter, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 86 to 89 per cent. v/v of ethyl alcohol.

TINCTURA LOBELIÆ SIMPLEX

(Tinct. Lobel. Simp.)

Simple Tincture of Lobelia

Synonym—Tinctura Lobeliæ.

	<i>Metric</i>	<i>Imperial</i>
Lobelia, in moderately fine powder	125 g.	2½ oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—0·6 to 2 millilitres (10 to 30 minims).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA LUPULI

(Tinct. Lupul.)

Tincture of Lupulus

Synonym—Tincture of Hops.

	<i>Metric</i>	<i>Imperial</i>
Lupulus	200 g.	4 oz.
Alcohol (60 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 55 to 59 per cent. v/v of ethyl alcohol.

TINCTURA LYCOPODII

(Tinct. Lycopod.)

Tincture of Lycopodium

	<i>Metric</i>	<i>Imperial</i>
Lycopodium	100 g.	2 oz.
Alcohol (90 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.—1 to 4 millilitres ($\frac{1}{4}$ to 1 fluid drachm).

Alcohol content, 85 to 89 per cent. v/v of ethyl alcohol.

TINCTURA MYRRHÆ COMPOSITA

(Tinct. Myrrh. Co.)

Compound Tincture of Myrrh*Synonym*—Tinctura Myrrhæ et Aloes.

	<i>Metric</i>	<i>Imperial</i>
Myrrh, crushed	50 g.	1 oz.
Aloes, crushed	50 g.	1 oz.
Distilled Water	250 ml.	5 fl. oz.
Alcohol (90 per cent.)	750 ml.	15 fl. oz.

Macerate for seven days with frequent agitation, and strain.

Alcohol content, 61 to 65 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

TINCTURA MYRRHÆ ET BORACIS

(Tinct. Myrrh. et Borac.)

Tincture of Myrrh and Borax

	<i>Metric</i>	<i>Imperial</i>
Tincture of Myrrh	350 ml.	7 fl. oz.
Tincture of Krameria	35 ml.	336 m.
Oil of Bergamot	2 ml.	20 m.
Oil of Lemon	2 ml.	20 m.
Oil of Orange	2 ml.	20 m.
Oil of Neroli	1 ml.	10 m.
Oil of Rosemary	2 ml.	20 m.
Borax, in powder	25 g.	$\frac{1}{2}$ oz.
Glycerin	50 ml.	1 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve the borax in the glycerin with the aid of gentle heat; cool, add the oils dissolved in part of the alcohol, the tincture of myrrh and tincture of krameria, and sufficient of the alcohol to produce the required volume.

Alcohol content, 76 to 80 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, and the tinctures of myrrh and krameria may be replaced by tinctures prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

TINCTURA OPII AMMONIATA

(Tinct. Opii Ammon.)

Ammoniated Tincture of Opium

		<i>Metric</i>	<i>Imperial</i>
Tincture of Opium	100 ml.	2 fl. oz.
Benzoic Acid	20 g.	175 gr.
Oil of Anise	5 ml.	48 m.
Dilute Solution of Ammonia	200 ml.	4 fl. oz.
Alcohol (90 per cent.)	to 1000 ml.	to 20 fl. oz.

Dissolve the oil of anise and the benzoic acid in 600 millilitres (12 fluid ounces) of the alcohol, add the tincture of opium and the dilute solution of ammonia, mix, filter, and add sufficient of the alcohol to produce the required volume.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 63 to 68 per cent. v/v of ethyl alcohol.

TINCTURA OPII CROCATI

(Tinct. Opii Croc.)

Tincture of Opium with Saffron*Synonym*—Sydenham's Laudanum.

		<i>Metric</i>	<i>Imperial</i>
Opium, sliced	100 g.	2 oz.
Cinnamon, bruised	10 g.	87½ gr.
Clove, bruised	10 g.	87½ gr.
Saffron	50 g.	1 oz.
Alcohol (20 per cent.)	a sufficient quantity	

Prepare a tincture by the maceration process, using 900 millilitres (18 fluid ounces) of the alcohol. Determine the proportion of morphine in the product, and add sufficient of the alcohol to produce a tincture of the required strength.

Standard.—Tincture of opium with saffron, determined by the method of the British Pharmacopœia for Tinctura Opii, contains not less than 0.95 per cent. and not more than 1.05 per cent. w/v of morphine, calculated as anhydrous.

Dose.—0.3 to 2 millilitres (5 to 30 minims).

Alcohol content, 15 to 17 per cent. v/v of ethyl alcohol.

TINCTURA PERSIONIS

(Tinct. Pers.)

Tincture of Cudbear

	<i>Metric</i>	<i>Imperial</i>
Cudbear, in powder	125 g.	2½ oz.
Alcohol (90 per cent.)	350 ml.	7 fl. oz.
Distilled Water to 1000 ml.	to 20 fl. oz.

Mix the cudbear with 250 grammes (5 ounces) of washed sand, and prepare a tincture by the percolation process, using as menstruum a mixture of the alcohol with 700 millilitres (14 fluid ounces) of distilled water, and adding more distilled water, if necessary, to produce the required volume.

Alcohol content, 28 to 31 per cent. v/v of ethyl alcohol.

TINCTURA PODOPHYLLI

(Tinct. Podoph.)

Tincture of Podophyllum

	<i>Metric</i>	<i>Imperial</i>
Resin of Podophyllum	36.5 g.	319½ gr.
Alcohol (90 per cent.) to 1000.0 ml.	to 20 fl. oz.

Add the resin of podophyllum to 900 millilitres (18 fluid ounces) of the alcohol, and set aside for twenty-four hours, shaking occasionally; then filter, and pass sufficient of the alcohol through the filter to produce the required volume.

Dose.—0.3 to 1 millilitre (5 to 15 minims).

Alcohol content, 85 to 88 per cent. v/v of ethyl alcohol.

TINCTURA PODOPHYLLI AMMONIATA

(Tinct. Podoph. Ammon.)

Ammoniated Tincture of Podophyllum

	<i>Metric</i>	<i>Imperial</i>
Resin of Podophyllum	20 g.	175 gr.
Aromatic Spirit of Ammonia ..	to 1000 ml.	to 20 fl. oz.

Add the resin of podophyllum to 900 millilitres (18 fluid ounces) of the aromatic spirit of ammonia, and set aside for twenty-four hours, shaking occasionally; filter, and pass sufficient of the aromatic spirit of ammonia through the filter to produce the required volume.

Dose.—0.6 to 1.2 millilitres (10 to 20 minims).

Alcohol content, 63 to 68 per cent. v/v of ethyl alcohol.

TINCTURA PRUNI SEROTINÆ

(Tinct. Prun. Serot.)

Tincture of Wild Cherry*Synonyms*—Tinctura Pruni Virginianæ; Tincture of Virginian Prune.

	<i>Metric</i>	<i>Imperial</i>
Wild Cherry Bark, in moderately coarse powder	200 g.	4 oz.
Alcohol (90 per cent.)	565 ml.	11 fl. oz. 144 m.
Distilled Water	365 ml.	7 fl. oz. 144 m.
Glycerin	100 ml.	2 fl. oz.

Mix the wild cherry bark with the distilled water, and set aside in a closed vessel for twenty-four hours; add the alcohol and complete the maceration process, adding the glycerin to the product.

Dose.—2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 45 to 50 per cent. v/v of ethyl alcohol.

TINCTURA PULSATILLÆ

(Tinct. Pulsat.)

Tincture of Pulsatilla

	<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Pulsatilla ..	100 ml.	2 fl. oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Mix.

Dose.—0.3 to 2 millilitres (5 to 30 minims).

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

TINCTURA PYRETHRI

(Tinct. Pyreth.)

Tincture of Pyrethrum

	<i>Metric</i>	<i>Imperial</i>
Pyrethrum Root, in moderately fine powder	200 g.	4 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Alcohol content, 65 to 69 per cent. v/v of ethyl alcohol.

TINCTURA PYRETHRI FLORIS

(Tinct. Pyreth. Flor.)

Tincture of Pyrethrum Flower

	<i>Metric</i>	<i>Imperial</i>
Pyrethrum Flower, in powder ..	250 g.	5 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

In making this preparation the alcohol (60 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

TINCTURA QUININÆ

(Tinct. Quinin.)

Tincture of Quinine

	<i>Metric</i>	<i>Imperial</i>
Quinine Hydrochloride	20 g.	175 gr.
Tincture of Orange	1000 ml.	20 fl. oz.

Dissolve.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 72 to 76 per cent. v/v of ethyl alcohol.

TINCTURA SENNÆ COMPOSITA

(Tinct. Senn. Co.)

Compound Tincture of Senna

	<i>Metric</i>	<i>Imperial</i>
Senna Leaf, in moderately coarse powder	200 g.	4 oz.
Caraway, in moderately coarse powder	25 g.	$\frac{1}{2}$ oz.
Coriander, in moderately coarse powder	25 g.	$\frac{1}{2}$ oz.
Glycerin	100 ml.	2 fl. oz.
Alcohol (45 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare 850 millilitres (17 fluid ounces) of tincture by the percolation process, using the alcohol as menstruum; add the glycerin and sufficient of the alcohol to produce the required volume.

Dose.— For repeated administration, 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm); for a single administration, 8 to 16 millilitres (2 to 4 fluid drachms).

Alcohol content, 35 to 39 per cent. v/v of ethyl alcohol.

TINCTURA SERPENTARIÆ

(Tinct. Serpent.)

Tincture of Serpentry

	<i>Metric</i>	<i>Imperial</i>
Serpentry, in moderately fine powder	200 g.	4 oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 56 to 59 per cent. v/v of ethyl alcohol.

TINCTURA SUMBUL

(Tinct. Sumb.)

Tincture of Sumbul

	<i>Metric</i>	<i>Imperial</i>
Sumbul, coarsely powdered	100 g.	2 oz.
Alcohol (70 per cent.)	1000 ml.	20 fl. oz.

Prepare by the maceration process.

Dose.— 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm).

Alcohol content, 64 to 67 per cent. v/v of ethyl alcohol.

TINCTURA VALERIANÆ SIMPLEX

(Tinct. Valerian. Simp.)

Simple Tincture of Valerian*Synonym*—Tinctura Valerianæ.

	<i>Metric</i>	<i>Imperial</i>
Valerian, in moderately fine powder	125 g.	2 $\frac{1}{2}$ oz.
Alcohol (60 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

Alcohol content, 55 to 58 per cent. v/v of ethyl alcohol.

TINCTURA VERATRI

(Tinct. Verat.)

Tincture of Green Hellebore*Synonym*—Tincture of Veratrum.

	<i>Metric</i>	<i>Imperial</i>
Green Hellebore, in moderately fine powder	100 g.	2 oz.
Alcohol (70 per cent.)	to 1000 ml.	to 20 fl. oz.

Prepare by the percolation process.

Dose.—0·3 to 2 millilitres (5 to 30 minims).

Alcohol content, 66 to 69 per cent. v/v of ethyl alcohol.

TROCHISCI**Lozenges**

Lozenges consist of a flavoured basis with which a medicament is incorporated, and are intended to be dissolved slowly in the mouth. They are generally prepared by mixing the drug, in powder or solution, with sucrose and acacia, then making the mixture into a paste with mucilage of acacia and the other ingredients, dividing the mass into lozenges by means of a suitable apparatus, and drying them in a hot-air chamber at a moderate temperature. The process of manufacture varies somewhat according to the basis employed. The quantities specified in the following formulæ are for one hundred lozenges in each case.

Lozenges with Fruit Basis

	<i>Metric</i>	<i>Imperial</i>
Sucrose, finely powdered ..	5 2 g.	80 gr.
Tragacanth, finely powdered ..	1·3 g.	20 gr.
Black Currant Paste, of commerce, to	130·0 g.	to 4 oz. 256 gr.

Mix the drug intimately with the sucrose and tragacanth, and make the mixture into a uniform mass with the black currant paste. Divide into 100 equal lozenges, and dry.

Lozenges with Rose Basis

	<i>Metric</i>	<i>Imperial</i>
Sucrose, finely powdered ..	100·0 g.	3 oz. 231 gr.
Acacia, finely powdered ..	7·0 g.	108 gr.
Oil of Rose	0·005 ml.	$\frac{1}{10}$ m.
Distilled Water	a sufficient quantity	

Mix the drug intimately with the sucrose and acacia, having previously mixed the sucrose with the oil of rose, and make the mixture into a paste with the distilled water. Divide into 100 equal lozenges, and dry.

Lozenges with Simple Basis

	<i>Metric</i>	<i>Imperial</i>
Sucrose, finely powdered	100·0 g.	3 oz. 231 gr.
Acacia, finely powdered . .	7·0 g.	108 gr.
Distilled Water	a sufficient quantity	

Mix the drug intimately with the sucrose and acacia, and make the mixture into a paste with the distilled water. Divide into 100 equal lozenges, and dry.

Lozenges with Tolu Basis

	<i>Metric</i>	<i>Imperial</i>
Sucrose, finely powdered	100·0 g.	3 oz. 231 gr.
Acacia, finely powdered . .	7·0 g.	108 gr.
Tincture of Tolu	2·0 ml.	34 m.
Distilled water	a sufficient quantity	

Mix the drug intimately with the sucrose and acacia, previously dissolving any alkaloidal salt ordered in 2 millilitres (34 minims) of distilled water; then add the tincture of tolu, and make the mixture into a paste with the distilled water. Divide into 100 equal lozenges, and dry. This tolu basis has the same composition as the basis employed in the general process for lozenges of the British Pharmacopœia.

Compressed Lozenges

Compressed lozenges can be made by the method described under *Tabellæ* for compressed tablets. The advantage of avoiding the application of heat is obvious in the case of volatile substances, but strong pressure is necessary, especially for lozenges intended to dissolve slowly.

TROCHISCI ACIDI BENZOICI

(Troch. Acid. Benz.)

Benzoic Acid Lozenges

	<i>Metric</i>	<i>Imperial</i>
Benzoic Acid	3·24 g.	50 gr.
Fruit Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI ALKALINI COMPOSITI

(Troch. Alk. Co.)

Compound Alkaline Lozenges

		<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	9.72 g.	150 gr.
Calcium Carbonate	29.16 g.	450 gr.
Heavy Magnesium Carbonate	29.16 g.	450 gr.
Sodium Bicarbonate	9.72 g.	150 gr.
Acacia, finely powdered	7.13 g.	110 gr.
Sucrose, finely powdered	77.11 g.	2 oz. 315 gr.
Distilled Water	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI AMMONII CHLORIDI COMPOSITI

(Troch. Ammon. Chlorid. Co.)

Compound Ammonium Chloride Lozenges*Synonym*—Trochisci Ammonii Chloridi et Glycyrrhizæ.

		<i>Metric</i>	<i>Imperial</i>
Ammonium Chloride	19.44 g.	300 gr.
Extract of Liquorice	19.44 g.	300 gr.
Fruit Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI ANTACIDI

(Troch. Antacid.)

Antacid Lozenges

		<i>Metric</i>	<i>Imperial</i>
Calcium Carbonate	22.68 g.	350 gr.
Heavy Magnesium Carbonate	16.20 g.	250 gr.
Sodium Chloride..	6.48 g.	100 gr.
Simple Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI CATECHU

(Troch. Catech.)

Catechu Lozenges

		<i>Metric</i>	<i>Imperial</i>
Catechu, in powder	6.48 g.	100 gr.
Fruit Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI CHLORODYNI

(Troch. Chlorod.)

Chlorodyne Lozenges

		<i>Metric</i>	<i>Imperial</i>
Morphine Hydrochloride	..	0·097 g.	1½ gr.
Chloroform	4·44 ml.	75 m.
Ether	0·83 ml.	14 m.
Oil of Peppermint	0·012 ml.	½ m.
Tincture of Capsicum	0·10 ml.	1¾ m.
Tragacanth, finely powdered	..	0·05 g.	¾ gr.
Sucrose, finely powdered	..	a sufficient quantity	
Mucilage of Acacia	..	to 156·00 g.	to 5½ oz.

Mix, and make into 100 lozenges.

TROCHISCI FERRI REDACTI

(Troch. Ferr. Redact.)

Reduced Iron Lozenges

		<i>Metric</i>	<i>Imperial</i>
Reduced Iron	6·48 g.	100 gr.
Simple Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI GLYCYRRHIZÆ

(Troch. Glycyrrh.)

Liquorice Lozenges*Synonym*—Brompton Cough Lozenges.

		<i>Metric</i>	<i>Imperial</i>
Extract of Liquorice	19·44 g.	300 gr.
Oil of Anise	2·96 ml.	50 m.
Simple Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI GUAIACI RESINÆ

(Troch. Guaiac. Res.)

Guaiacum Resin Lozenges

		<i>Metric</i>	<i>Imperial</i>
Guaiacum Resin, in powder		19·44 g.	300 gr.
Fruit Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI IPECACUANHÆ

(Troch. Ipecac.)

Ipecacuanha Lozenges

	<i>Metric</i>	<i>Imperial</i>
Powdered Ipecacuanha	1.62 g.	25 gr.
Simple Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI KINO EUCALYPTI

(Troch. Kino Eucalyp.)

Eucalyptus Kino Lozenges

Synonyms—Red Gum Lozenges; Eucalyptus Gum Lozenges.

	<i>Metric</i>	<i>Imperial</i>
Eucalyptus Kino, in powder ..	6.48 g.	100 gr.
Fruit Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI MORPHINÆ

(Troch. Morph.)

Morphine Lozenges

	<i>Metric</i>	<i>Imperial</i>
Morphine Hydrochloride ..	0.194 g.	3 gr.
Tolu Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI POTASSII CHLORATIS

(Troch. Pot. Chlorat.)

Potassium Chlorate Lozenges

	<i>Metric</i>	<i>Imperial</i>
Potassium Chlorate, in powder ..	19.44 g.	300 gr.
Rose Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI SANTONINI

(Troch. Santonin.)

Santonin Lozenges

		<i>Metric</i>	<i>Imperial</i>
Santonin, in powder	6.48 g.	100 gr.
Simple Basis	a sufficient quantity	

Mix, and make into 100 lozenges.

TROCHISCI SULPHURIS

(Troch. Sulphur.)

Sulphur Lozenges

		<i>Metric</i>	<i>Imperial</i>
Precipitated Sulphur	32.40 g.	1 oz. 62½ gr.
Potassium Acid Tartrate	6.48 g.	100 gr.
Sucrose, finely powdered	59.40 g.	2 oz. 42 gr.
Acacia, finely powdered	6.48 g.	100 gr.
Tincture of Orange	6.48 ml.	110 m.
Mucilage of Acacia	6.48 ml.	110 m.

Mix, and make into 100 lozenges.

UNGUENTA**Ointments**

Ointments are semi-solid preparations intended for local application. In tropical and sub-tropical climates varying proportions of fats and waxes may be employed in the preparation of ointments, in order to meet conditions of temperature, but the proportions of the active ingredients must in all cases be maintained. Ointments are usually dispensed in covered pots. For nasal, ophthalmic and rectal use, collapsible tin tubes with applicator nozzles are to be recommended. When a definite quantity of ointment is ordered for inunction, it may be dispensed in graduated tubes, soft gelatin capsules, or in portions wrapped in grease-proof paper.

When a solid substance is to be incorporated in an ointment it should be in the finest possible powder. It should first be mixed with a small portion of the basis which has been previously melted, or, in some cases, with a small quantity of olive oil if the basis is a fatty one which is intended to be absorbed, or with liquid paraffin if not to be absorbed. Trituration should be continued until a smooth paste is obtained, the

remainder of the basis can then be incorporated in increasingly large portions. Caution should be exercised in the use of steel spatulas since, in the presence of moisture, tannic acid, salicylic acid, iodine and mercuric chloride act on the steel.

UNGUENTUM ACIDI BENZOICI COMPOSITUM

(Ung. Acid. Benz. Co.)

Compound Benzoic Acid Ointment

Synonym—Whitfield's Ointment.

		<i>Metric</i>	<i>Imperial</i>
Benzoic Acid, finely sifted	..	5.0 g.	87½ gr.
Salicylic Acid, finely sifted	..	3.0 g.	52½ gr.
White Soft Paraffin	..	27.6 g.	1 oz. 45½ gr.
Coconut Oil	..	64.4 g.	2 oz. 252 gr.

Add the benzoic and salicylic acids to the soft paraffin and coconut oil, previously melted together at as low a temperature as possible, and stir until cold.

UNGUENTUM ACIDI BORICI FLAVUM

(Ung. Acid. Boric. Flav.)

Yellow Boric Acid Ointment

		<i>Metric</i>	<i>Imperial</i>
Boric Acid, finely sifted	..	10 g.	175 gr.
Yellow Soft Paraffin	..	90 g.	3 oz. 262½ gr.

Triturate the boric acid with a portion of the yellow soft paraffin until smooth; add the remainder, and mix thoroughly.

UNGUENTUM ACONITINÆ

(Ung. Aconitin.)

Aconitine Ointment

		<i>Metric</i>	<i>Imperial</i>
Aconitine	..	2 g.	35 gr.
Oleic Acid	..	16 g.	280 gr.
Lard	..	82 g.	3 oz. 122½ gr.

Triturate the aconitine with the oleic acid, gently warm the mixture until the alkaloid is dissolved and mix with the lard.

UNGUENTUM ADIPIS LANÆ

(Ung. Adip. Lan.)

Wool Fat Ointment*Synonyms*—Unguentum Lanolini Anhydrosi; Anhydrous Lanolin Ointment.

			<i>Metric</i>	<i>Imperial</i>
Wool Fat	50 g.	2 oz.
Yellow Soft Paraffin	50 g.	2 oz.
Mix.				

UNGUENTUM ADIPIS LANÆ COMPOSITUM

(Ung. Adip. Lan. Co.)

Compound Wool Fat Ointment*Synonyms*—Unguentum Lanæ Compositum; Emollient Ointment.

			<i>Metric</i>	<i>Imperial</i>
Lard	40 g.	1 oz. 262½ gr.
Wool Fat	40 g.	1 oz. 262½ gr.
Paraffin Ointment, yellow	20 g.	350 gr.

Melt together, and stir until cold.

UNGUENTUM ADIPIS LANÆ HYDROSI

(Ung. Adip. Lan. Hydros.)

Hydrous Wool Fat Ointment*Synonyms*—Unguentum Lanolini; Lanolin Ointment.

			<i>Metric</i>	<i>Imperial</i>
Hydrous Wool Fat	50 g.	2 oz.
Yellow Soft Paraffin	50 g.	2 oz.
Mix.				

UNGUENTUM ADRENALINÆ

(Ung. Adrenal.)

Adrenaline Ointment

			<i>Metric</i>	<i>Imperial</i>
Adrenaline	0.1 g.	1½ gr.
Boric Acid	0.2 g.	3½ gr.
Distilled Water	3.0 ml.	57¾ m.
Hydrous Wool Fat	50.0 g.	2 oz.
White Soft Paraffin	46.7 g.	1 oz. 379¾ gr.

Dissolve the boric acid in the warmed distilled water, add the adrenaline, mix the solution with the hydrous wool fat, and incorporate the soft paraffin.

UNGUENTUM ADRENALINÆ ET AMYLOCAINÆ COMPOSITUM

(Ung. Adrenal. et Amylocain. Co.)

Compound Ointment of Adrenaline and Amylocaine

	<i>Metric</i>	<i>Imperial</i>
Adrenaline	0.007 g.	$\frac{1}{10}$ gr.
Benzoic Acid	0.06 g.	1 gr.
Amylocaine Hydrochloride, finely sifted	1.00 g.	17 $\frac{1}{2}$ gr.
Benzocaine, finely sifted	1.00 g.	17 $\frac{1}{2}$ gr.
Liquid Extract of Hamamelis	7.50 ml.	144 m.
Wool Fat	30.00 g.	1 oz. 87 $\frac{1}{2}$ gr.
Yellow Soft Paraffin	to 100.00 g.	to 4 oz.

Dissolve the benzoic acid in the liquid extract of hamamelis, add the adrenaline, and stir until dissolved; mix the solution with the wool fat previously mixed with part of the yellow soft paraffin, then incorporate the powders and sufficient yellow soft paraffin to produce the required weight.

In making this preparation the liquid extract of hamamelis may be replaced by a liquid extract of hamamelis prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

UNGUENTUM ADRENALINÆ ET COCAINÆ

(Ung. Adrenal. et Cocain.)

Adrenaline and Cocaine Ointment

	<i>Metric</i>	<i>Imperial</i>
Adrenaline	0.1 g.	1 $\frac{1}{2}$ gr.
Boric Acid	0.2 g.	3 $\frac{1}{2}$ gr.
Cocaine Hydrochloride	1.0 g.	17 $\frac{1}{2}$ gr.
Distilled Water	3.0 ml.	58 m.
Hydrous Wool Fat	50.0 g.	2 oz.
White Soft Paraffin	45.7 g.	1 oz. 362 $\frac{1}{4}$ gr.

Dissolve the boric acid in the warmed distilled water, add the adrenaline and cocaine hydrochloride, mix the solution with the hydrous wool fat, and incorporate the white soft paraffin.

UNGUENTUM AQUÆ ROSÆ**(Ung. Aq. Ros.)****Rose Water Ointment**

			<i>Metric</i>	<i>Imperial</i>
Rose Water	20.0 ml.	384 m.
White Beeswax	18.0 g.	315 gr.
Borax	1.0 g.	17½ gr.
Almond Oil	61.0 g.	2 oz. 192½ gr.
Oil of Rose	0.1 ml.	2 m.

Melt the beeswax in the almond oil and add, with constant stirring, the borax previously dissolved in the rose water; add the oil of rose, and continue to stir until cold.

UNGUENTUM ATROPINÆ**(Ung. Atrop.)****Atropine Ointment**

			<i>Metric</i>	<i>Imperial</i>
Atropine	1 g.	17½ gr.
White Soft Paraffin	99 g.	3 oz. 420 gr.

Dissolve the atropine in the white soft paraffin with the aid of gentle heat.

UNGUENTUM BELLADONNÆ**(Ung. Bellad.)****Belladonna Ointment**

			<i>Metric</i>	<i>Imperial</i>
Liquid Extract of Belladonna	80 ml.	4 fl. oz.
Benzoinated Lard	60 g.	3 oz.
Wool Fat	20 g.	1 oz.

Evaporate the liquid extract of belladonna on a water-bath until it is reduced to 20 grammes (1 ounce), and mix it with the benzoinated lard and wool fat.

In making this preparation the liquid extract of belladonna may be replaced by a liquid extract of belladonna prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

UNGUENTUM BETANAPHTHOLIS COMPOSITUM

(Ung. Betanaph. Co.)

Compound Betanaphthol Ointment

Synonyms—Kaposi's Compound Ointment; Unguentum Naphthol Compositum; Compound Naphthol Ointment.

		<i>Metric</i>	<i>Imperial</i>
Betanaphthol, finely sifted	..	8.57 g.	150 gr.
Chalk, finely sifted	5.71 g.	100 gr.
Soft Soap	28.50 g.	1 oz. 61½ gr.
Lard	57.22 g.	2 oz. 126¼ gr.

Mix thoroughly by trituration.

UNGUENTUM BISMUTHI

(Ung. Bism.)

Bismuth Ointment

		<i>Metric</i>	<i>Imperial</i>
Bismuth Carbonate	12.5 g.	½ oz.
White Soft Paraffin	87.5 g.	3½ oz.

Mix thoroughly by trituration.

UNGUENTUM BISMUTHI OLEATIS

(Ung. Bism. Oleat.)

Bismuth Oleate Ointment

		<i>Metric</i>	<i>Imperial</i>
Bismuth Oleate	12.5 g.	½ oz.
White Soft Paraffin	87.5 g.	3½ oz.

Mix thoroughly by trituration.

UNGUENTUM CALAMINÆ

(Ung. Calamin.)

Calamine Ointment

		<i>Metric</i>	<i>Imperial</i>
Calamine	16.7 g.	292½ gr.
Yellow Soft Paraffin	83.3 g.	3 oz. 145½ gr.

Mix thoroughly by trituration.

UNGUENTUM CAMPHORÆ

(Ung. Camph.)

Camphor Ointment

		<i>Metric</i>	<i>Imperial</i>
Camphor, in flowers	. .	10 g.	175 gr.
White Soft Paraffin	. .	90 g.	3 oz. 262½ gr.

Dissolve the camphor in the soft paraffin, previously melted at as low a temperature as possible, and stir until cold.

UNGUENTUM CAMPHORÆ DURUM

(Ung. Camph. Dur.)

Hard Camphor Ointment*Synonym:*—Camphor Ice.

		<i>Metric</i>	<i>Imperial</i>
Camphor, in flowers	. .	6 g.	105 gr.
Hard Paraffin	. .	26 g.	455 gr.
White Soft Paraffin	. .	68 g.	2 oz. 315 gr.

Dissolve the camphor in the hard and soft paraffins, previously melted at as low a temperature as possible, and stir until cold.

When a harder preparation is required the proportion of hard paraffin may be increased.

UNGUENTUM CANTHARIDINI

(Ung. Cantharidin.)

Cantharidin Ointment

		<i>Metric</i>	<i>Imperial</i>
Cantharidin	. . .	0.1 g.	1 gr.
Chloroform	. . .	10.0 ml.	110 m.
Benzoinated Lard	. . .	290.0 g.	6 oz. 275 gr.

Dissolve the cantharidin in the chloroform; add the solution to the benzoinated lard, previously melted, and stir until cold.

UNGUENTUM CAPSICI COMPOSITUM

(Ung. Capsic. Co.)

Compound Capsicum Ointment

Synonyms—Unguentum Oleoresinæ Capsici Compositum; Compound Capsicum Oleoresin Ointment; Chillie Paste.

	<i>Metric</i>	<i>Imperial</i>
Oleoresin of Capsicum	2 g.	35 gr.
Menthol	10 g.	175 gr.
Chloral Hydrate	10 g.	175 gr.
Camphor	10 g.	175 gr.
Yellow Soft Paraffin	68 g.	2 oz. 315 gr.

Dissolve the oleoresin of capsicum in the melted yellow soft paraffin, and incorporate the menthol, chloral hydrate and camphor previously triturated until liquefied.

UNGUENTUM CAPSICI FORTE

(Ung. Capsic. Fort.)

Strong Capsicum Ointment

Synonyms—Unguentum Oleoresinæ Capsici; Capsicum Oleoresin Ointment.

	<i>Metric</i>	<i>Imperial</i>
Oleoresin of Capsicum	4.5 g.	78½ gr.
Yellow Beeswax ..	9.0 g.	157½ gr.
Benzoinated Lard	86.5 g.	3 oz. 201¼ gr.

Melt the yellow beeswax and benzoinated lard at a low temperature, add the oleoresin of capsicum, mix thoroughly, and stir until cold.

UNGUENTUM CETACEI

(Ung. Cetac.)

Spermaceti Ointment

	<i>Metric</i>	<i>Imperial</i>
Spermaceti	20 g.	350 gr.
White Beeswax	8 g.	140 gr.
Liquid Paraffin	to 100 g.	to 4 oz.

Melt together, and stir until cold.

UNGUENTUM CHAULMOOGRÆ

(Ung. Chaulmoog.)

Chaulmoogra Ointment*Synonym*—Gynocardia Ointment

	<i>Metric</i>	<i>Imperial</i>
Chaulmoogra Oil	10 g.	175 gr.
Hard Paraffin	40 g.	1 oz. 262½ gr.
White Soft Paraffin	50 g.	2 oz.

Melt the hard and soft paraffins together, add the chaulmoogra oil, and stir until cold.

UNGUENTUM CHRYSAROBINI COMPOSITUM

(Ung. Chrysarol Co.)

Compound Chrysarobin Ointment

	<i>Metric</i>	<i>Imperial</i>
Chrysarobin, finely sifted	5 g.	87½ gr.
Ichthammol	5 g.	87½ gr.
Salicylic Acid, finely sifted	2 g.	35 gr.
Yellow Soft Paraffin	88 g.	3 oz. 227½ gr.

Mix thoroughly by trituration.

UNGUENTUM COCAINÆ

(Ung. Cocain.)

Cocaine Ointment

	<i>Metric</i>	<i>Imperial</i>
Cocaine	4 g.	70 gr.
Oleic Acid	16 g.	280 gr.
Lard	80 g.	3 oz. 87½ gr.

Triturate the cocaine with the oleic acid, gently warm the mixture until the alkaloid is dissolved, and mix with the lard.

UNGUENTUM HYDRARGYRI OXIDI FLAVI HUMIDI

(Ung. Hydrarg. Oxid. Flav. Humid.)

Moist Yellow Mercuric Oxide Ointment

	<i>Metric</i>	<i>Imperial</i>
Mercuric Chloride ..	12.50 g.	$\frac{1}{2}$ oz.
Sodium Hydroxide ..	5.416 g.	95 gr.
Distilled Water ..	a sufficient quantity	
Wool Fat ..	12.50 g.	$\frac{1}{2}$ oz.
Yellow Soft Paraffin ..	to 100.00 g.	to 4 oz.

Dissolve the mercuric chloride in 400 millilitres (16 fluid ounces) of warm distilled water, dissolve the sodium hydroxide in an equal volume of cold distilled water, filter both solutions, and pour slowly, with constant stirring, the mercuric chloride solution into the sodium hydroxide solution. Set the mixture aside in a dark place until the precipitate has subsided, then decant the clear liquid, and wash the precipitate, by decantation or on a linen filter, with successive portions of warm distilled water, until the washings are free from chloride and alkali. Allow to drain, transfer to a mortar, and incorporate the wool and sufficient yellow soft paraffin to produce the required weight. The finished product contains about 10 per cent. of yellow mercuric oxide.

UNGUENTUM HYDRARGYRI OXIDI RUBRI

(Ung. Hydrarg. Oxid. Rub.)

Red Mercuric Oxide Ointment*Synonym*—Red Precipitate Ointment.

	<i>Metric</i>	<i>Imperial</i>
Red Mercuric Oxide, in powder	10 g.	175 gr.
Paraffin Ointment, yellow ..	90 g.	3 oz. 26 $\frac{1}{2}$ gr.

Melt the paraffin ointment, sift in the red mercuric oxide, and stir until cold.

UNGUENTUM HYDRARGYRI, PLUMBI ET ZINCI

(Ung. Hydrarg. Plumb. et Zinc.)

Mercury, Lead and Zinc Ointment*Synonym*—Unguentum Metallorum.

	<i>Metric</i>	<i>Imperial</i>
Strong Ointment of Mercuric Nitrate	30 g.	1 oz.
Lead Subacetate Ointment ..	30 g.	1 oz.
Ointment of Zinc Oxide ..	30 g.	1 oz.

Mix.

UNGUENTUM HYDRARGYRI SUBCHLORIDI COMPOSITUM

(Ung. Hydrarg. Subchlor. Co.)

Compound Mercurous Chloride Ointment

Synonym.—Calomel Cream; Prophylactic Ointment.

			<i>Metric</i>	<i>Imperial</i>
Mercurous Chloride	25·0 g.	1 oz.
Mercuric Oxycyanide	0·075 g.	1½ gr.
Wool Fat	35·0 g.	1 oz. 175 gr.
Yellow Soft Paraffin	25·0 g.	1 oz.
Liquid Paraffin	15·0 g.	262½ gr.

Melt together the wool fat, yellow soft paraffin and liquid paraffin; reduce the mercuric oxycyanide and mercurous chloride to fine powder, and triturate them with a portion of the melted basis until smooth; gradually add the remainder, mixing thoroughly by trituration until cold. (Care should be taken to use dry ingredients and to avoid the inclusion of moisture.)

UNGUENTUM ICHTHAMMOLIS

(Ung. Ichtham.)

Ichthammol Ointment

Synonym.—Ammonium Ichthosulphonate Ointment.

			<i>Metric</i>	<i>Imperial</i>
Ichthammol	10 g.	175 gr.
Wool Fat Ointment	90 g.	3 oz. 262½ gr.
Mix.				

UNGUENTUM ICHTHAMMOLIS COMPOSITUM

(Ung. Ichtham. Co.)

Compound Ichthammol Ointment

Synonym.—Compound Ammonium Ichthosulphonate Ointment.

			<i>Metric</i>	<i>Imperial</i>
Ichthammol	9 g.	157½ gr.
Precipitated Sulphur, finely sifted			9 g.	157½ gr.
Zinc Oxide, finely sifted	9 g.	157½ gr.
Starch, finely sifted	9 g.	157½ gr.
Distilled Water	6 ml.	115 m.
Resorcinol	4 g.	70 gr.
Salicylic Acid, finely sifted	2 g.	35 gr.
Betanaphthol, finely sifted	2 g.	35 gr.
Wool Fat Ointment	50 g.	2 oz.

Dissolve the resorcinol in the distilled water, incorporate the solution with the wool fat ointment, mix in the ichthammol, and then incorporate the powders, previously mixed.

UNGUENTUM IODI

(Ung. Iod.)

Iodine Ointment

	<i>Metric</i>	<i>Imperial</i>
Iodine	4 g.	70 gr.
Potassium Iodide	4 g.	70 gr.
Water	4 ml.	77 m.
Simple Ointment, yellow	88 g.	3 oz. 227½ gr.

Dissolve the iodine and potassium iodide in the distilled water, and mix the solution with the simple ointment.

UNGUENTUM IODI DENIGRESCENS

(Ung. Iod. Denig.)

Non-staining Iodine Ointment.

	<i>Metric</i>	<i>Imperial</i>
Iodine	5 g.	87½ gr.
Arachis Oil	15 ml.	288 m.
Yellow Soft Paraffin	to 100 g.	to 4 oz.

Mix the iodine with the arachis oil, add the yellow soft paraffin, and heat gently, with occasional stirring, at a temperature not exceeding 60° until complete combination is effected, as indicated by the disappearance of the brown colour.

UNGUENTUM IODOFORMI

(Ung. Iodof.)

Iodoform Ointment

	<i>Metric</i>	<i>Imperial</i>
Iodoform, finely sifted	10 g.	175 gr.
Simple Ointment, yellow	90 g.	3 oz. 26½ gr.

Mix thoroughly by trituration.

It should be **stored** protected from light, and in a cool place.

UNGUENTUM IODOFORMI ET EUCALYPTI

(Ung. Iodof. et Eucalyp.)

Iodoform and Eucalyptus Ointment

				<i>Metric</i>	<i>Imperial</i>
Iodoform	2.00 g.	35 gr.
Oil of Eucalyptus	18.75 g.	$\frac{3}{4}$ oz.
Hard Paraffin	12.50 g.	$\frac{1}{2}$ oz.
Yellow Soft Paraffin	66.75 g.	2 oz. 293 gr.

Heat the iodoform gently with the oil of eucalyptus until solution is effected; add to the hard and soft paraffins previously melted together, and stir until cold.

UNGUENTUM KAOLINI

(Ung. Kaolin.)

Kaolin Ointment*Synonyms*—Massa Kaolini; Kaolin Mass.

				<i>Metric</i>	<i>Imperial</i>
Kaolin, finely sifted	25 g.	1 oz.
White Soft Paraffin	50 g.	2 oz.
Hard Paraffin	25 g.	1 oz.

Mix the kaolin with the melted hard and soft paraffins, and stir until cold.

UNGUENTUM MERCURIALE

(Ung. Mercur.)

Mercurial Ointment

Synonyms—Unguentum Hydrargyri Mite; Blue Ointment; Trooper's Ointment.

				<i>Metric</i>	<i>Imperial</i>
Ointment of Mercury	33 g.	1 oz. 145 $\frac{3}{4}$ gr.
Lard	66 g.	2 oz. 291 $\frac{1}{2}$ gr.

Mix.

UNGUENTUM METHYLIS SALICYLATIS

(Ung. Methyl. Salicyl.)

Methyl Salicylate Ointment

Synonyms—Unguentum Methylis Salicylatis Forte; Strong Methyl Salicylate Ointment.

				<i>Metric</i>	<i>Imperial</i>
Methyl Salicylate	50 g.	2 oz.
White Beeswax	25 g.	1 oz.
Hydrous Wool Fat	25 g.	1 oz.

Melt together the beeswax and hydrous wool fat, add the methyl salicylate, and stir until cold.

UNGUENTUM METHYLIS SALICYLATIS COMPOSITUM

(Ung. Methyl. Salicyl. Co.)

Compound Methyl Salicylate Ointment

Synonyms—Unguentum Methylis Salicylatis Compositum Forte;
Strong Compound Ointment of Methyl Salicylate; Unguentum
Betulæ Compositum; Unguentum Analgesicum; Analgesic
Balsam.

			<i>Metric</i>	<i>Imperial</i>
Methyl Salicylate	50.0 g.	2 oz.
Menthol	10.0 g.	175 gr.
Eucalyptol	2.5 g.	43 $\frac{3}{4}$ gr.
Oil of Cajuput	2.5 g.	43 $\frac{3}{4}$ gr.
White Beeswax	20.0 g.	350 gr.
Hydrous Wool Fat	15.0 g.	262 $\frac{1}{2}$ gr.

Melt together the beeswax and hydrous wool fat, add the menthol dissolved in the mixed liquids, and stir until cold.

UNGUENTUM METHYLIS SALICYLATIS COMPOSITUM DILUTUM

(Ung. Methyl. Salicyl. Co. Dil.)

Dilute Compound Methyl Salicylate Ointment

			<i>Metric</i>	<i>Imperial</i>
Compound Methyl Salicylate				
Ointment	25 g.	1 oz.
Hydrous Wool Fat Ointment	..		75 g.	3 oz.
Mix.				

UNGUENTUM METHYLIS SALICYLATIS DILUTUM

(Ung. Methyl. Salicyl. Dil.)

Dilute Methyl Salicylate Ointment

			<i>Metric</i>	<i>Imperial</i>
Methyl Salicylate Ointment	..		25 g.	1 oz.
Hydrous Wool Fat Ointment	..		75 g.	3 oz.
Mix.				

UNGUENTUM OLEI CADINI

(Ung. Ol. Cadin.)

Oil of Cade Ointment

	<i>Metric</i>	<i>Imperial</i>
Oil of Cade	25.0 g.	1 oz.
Yellow Beeswax	12.5 g.	$\frac{1}{2}$ oz.
Yellow Soft Paraffin	62.5 g.	$2\frac{1}{2}$ oz.

Melt together the yellow beeswax and yellow soft paraffin, add the oil of cade, and stir until cold.

UNGUENTUM OLEI COCOIS

(Ung. Ol. Cocois)

Coconut Oil Ointment

	<i>Metric</i>	<i>Imperial</i>
Coconut Oil	70 g.	2 oz. 350 gr.
White Soft Paraffin	30 g.	1 oz. 87 $\frac{1}{2}$ gr.
Mix.		

UNGUENTUM PERUVIANUM

(Ung. Peruv.)

Balsam of Peru Ointment

	<i>Metric</i>	<i>Imperial</i>
Balsam of Peru	12.5 g.	$\frac{1}{2}$ oz.
Simple Ointment, yellow	87.5 g.	$3\frac{1}{2}$ oz.
Mix.		

UNGUENTUM PHENOLIS COMPOSITUM

(Ung. Phenol. Co.)

Compound Phenol Ointment

Synonyms—Unguentum Acidi Carbolici Compositum; Compound Carbolic Acid Ointment.

	<i>Metric</i>	<i>Imperial</i>
Phenol	18 g.	318 gr.
Strong Ointment of Mercuric Nitrate	36 g.	1 oz. 199 gr.
Sublimed Sulphur, finely sifted	9 g.	159 gr.
Olive Oil	18 g.	318 gr.
Yellow Beeswax	18 g.	318 gr.

Heat the olive oil with the sulphur until a reddish-brown liquid is obtained, dissolve the beeswax in the mixture, stir until nearly cold, then add the phenol, stir until dissolved, and mix with the strong ointment of mercuric nitrate.

UNGUENTUM PICIS CARBONIS

(Ung. Pic. Carbon.)

Coal Tar Ointment

			<i>Metric</i>	<i>Imperial</i>
Solution of Coal Tar	6.25 ml.	120 m.
Yellow Soft Paraffin	93.75 g.	3 $\frac{3}{4}$ oz.

Mix.

UNGUENTUM PICIS CARBONIS COMPOSITUM

(Ung. Pic. Carbon. Co.)

Compound Coal Tar Ointment

			<i>Metric</i>	<i>Imperial</i>
Solution of Coal Tar	6.25 ml.	120 m.
Ammoniated Mercury	3.12 g.	54 $\frac{3}{4}$ gr.
Yellow Soft Paraffin	90.63 g.	3 oz. 273 $\frac{1}{2}$ gr.

Triturate the ammoniated mercury with a portion of the yellow soft paraffin until smooth, mix with the remainder of the yellow soft paraffin, and incorporate the solution of coal tar.

UNGUENTUM PICIS LIQUIDÆ

(Ung. Pic. Liq.)

Tar Ointment

				<i>Metric</i>	<i>Imperial</i>
Tar	70 g.	2 oz. 350 gr.
Lard	5 g.	87 $\frac{1}{2}$ gr.
Yellow Beeswax	25 g.	1 oz.

Melt together, and stir until cold.

UNGUENTUM PLUMBI ACETATIS

(Ung. Plumb. Acet.)

Lead Acetate Ointment

		<i>Metric</i>	<i>Imperial</i>
Lead Acetate, finely sifted	..	4 g.	70 gr.
Paraffin Ointment, white	..	96 g.	3 oz. 367½ gr.

Mix thoroughly by trituration.

UNGUENTUM PLUMBI CARBONATIS

(Ung. Plumb. Carb.)

Lead Carbonate Ointment

		<i>Metric</i>	<i>Imperial</i>
Lead Carbonate, finely sifted	..	10 g.	175 gr.
Paraffin Ointment, white	..	90 g.	3 oz. 262½ gr.

Mix thoroughly by trituration.

UNGUENTUM PLUMBI IODIDI

(Ung. Plumb. Iod.)

Lead Iodide Ointment

		<i>Metric</i>	<i>Imperial</i>
Lead Iodide, finely sifted	..	10 g.	175 gr.
Benzoinated Lard	90 g.	3 oz. 262½ gr.

Mix thoroughly by trituration.

UNGUENTUM PLUMBI OLEATIS

(Ung. Plumb. Oleat.)

Lead Oleate Ointment

Synonyms—Unguentum Diachylon; Diachylon Ointment; Hebra's Ointment.

		<i>Metric</i>	<i>Imperial</i>
Plaster of Lead	50 g.	2 oz.
Oil of Lavender	1 g.	17½ gr.
Olive Oil	49 g.	1 oz. 420 gr.

Melt together the plaster of lead and olive oil, stir until cold, and incorporate the oil of lavender.

It should be freshly prepared.

UNGUENTUM PLUMBI SUBACETATIS

(Ung. Plumb. Subacet.)

Lead Subacetate Ointment

	<i>Metric</i>	<i>Imperial</i>
Strong Solution of Lead Subacetate	12.5 g.	$\frac{1}{2}$ oz.
Wool Fat	25.0 g.	1 oz.
Hard Paraffin	12.5 g.	$\frac{1}{2}$ oz.
White Soft Paraffin	50.0 g.	2 oz.

Melt together the wool fat and the hard and soft paraffins, stir until nearly cold, add the strong solution of lead subacetate, and continue stirring until cold.

UNGUENTUM POTASSII IODIDI

(Ung. Pot. Iod.)

Potassium Iodide Ointment

	<i>Metric</i>	<i>Imperial</i>
Potassium Iodide	10.0 g.	175 gr.
Potassium Carbonate	0.6 g.	10 $\frac{1}{2}$ gr.
Distilled Water	9.4 ml.	180 $\frac{1}{2}$ ml.
Benzoinated Lard	80.0 g.	3 oz. 87 $\frac{1}{2}$ gr.

Dissolve the potassium iodide and potassium carbonate in the distilled water, and mix the solution gradually with the benzoinated lard in a slightly warmed mortar.

UNGUENTUM POTASSII POLYSULPHIDI

(Ung. Pot. Polysulph.)

Potassium Polysulphide Ointment

Synonyms—Marcussen's Ointment; Danish Ointment.

	<i>Metric</i>	<i>Imperial</i>
Potassium Hydroxide	12.5 g.	$\frac{1}{2}$ oz.
Sublimed Sulphur	12.5 g.	$\frac{1}{2}$ oz.
Yellow Soft Paraffin	22.5 g.	394 gr.
Wool Fat	22.5 g.	394 gr.
Zinc Sulphate	2.8 g.	49 gr.
Sodium Hydroxide	0.8 g.	14 gr.
Distilled Water	15.7 ml.	302 m.
Benzaldehyde	0.5 ml.	10 m.
Liquid Paraffin	to 100.0 g.	to 4 oz.

Dissolve the potassium hydroxide in an equal weight of water, add the sulphur, boil gently until dissolved, and mix the solution with the

yellow soft paraffin and the wool fat. Dissolve the sodium hydroxide in the remainder of the distilled water, add the zinc sulphate, shake well, and incorporate the mixture with the ointment; then add the benzaldehyde and sufficient liquid paraffin to produce the required weight.

UNGUENTUM PYROGALLOLIS

(Ung. Pyrogall.)

Pyrogallol Ointment

Synonyms—Unguentum Acidi Pyrogallici; Pyrogallic Acid Ointment.

	<i>Metric</i>	<i>Imperial</i>
Pyrogallol, finely sifted	12.5 g.	$\frac{1}{2}$ oz.
White Soft Paraffin	87.5 g.	3 $\frac{1}{2}$ oz.

Mix thoroughly by trituration.

UNGUENTUM PYROGALLOLIS COMPOSITUM

(Ung. Pyrogall. Co.)

Compound Ointment of Pyrogallol

Synonyms—Unguentum Acidi Pyrogallici Compositum; Compound Pyrogallic Acid Ointment; Unna's Compound Pyrogallol Ointment.

	<i>Metric</i>	<i>Imperial</i>
Pyrogallol, finely sifted	5 g.	87 $\frac{1}{2}$ gr.
Ichthammol	5 g.	87 $\frac{1}{2}$ gr.
Salicylic Acid, finely sifted ..	2 g.	35 gr.
Yellow Soft Paraffin	88 g.	3 oz. 227 $\frac{1}{2}$ gr.

Mix thoroughly by trituration.

UNGUENTUM RESORCINOLIS

(Ung. Resorcin.)

Resorcinol Ointment

Synonyms—Unguentum Resorcini; Resorcin Ointment.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	12.5 g.	$\frac{1}{2}$ oz.
Glycerin	12.5 g.	$\frac{1}{2}$ oz.
Wool Fat	37.5 g.	1 $\frac{1}{2}$ oz.
White Soft Paraffin	37.5 g.	1 $\frac{1}{2}$ oz.

Dissolve the resorcinol in the glycerin, mix the solution with the wool fat, and add the soft paraffin.

UNGUENTUM RESORCINOLIS COMPOSITUM

(Ung. Resorcin. Co.)

Compound Resorcinol Ointment*Synonyms*—Unguentum Resorcini Compositum; Compound Resorcin Ointment.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	4.0 g.	70 gr.
Distilled Water	4.0 ml.	77 m.
Bismuth Subnitrate, finely sifted	8.0 g.	140 gr.
Zinc Oxide, finely sifted ..	4.0 g.	70 gr.
Starch, finely sifted	10.0 g.	175 gr.
Birch Tar Oil	3.0 g.	52½ gr.
Wool Fat	10.0 g.	175 gr.
Potassium Pyrosulphite	0.2 g.	3½ gr.
Ceresin, white	2.0 g.	35 gr.
Yellow Soft Paraffin	54.8 g.	2 oz. 84 gr.

Mix the bismuth subnitrate, zinc and starch with a portion of the soft paraffin, then add the wool fat and melted ceresin, to this add the resorcinol and potassium pyrosulphite previously dissolved in the water, lastly add the birch tar oil and the remainder of the soft paraffin.

UNGUENTUM RESORCINOLIS ET BISMUTHI COMPOSITUM

(Ung. Resorcin. et Bism. Co.)

Compound Resorcinol and Bismuth Ointment*Synonyms*—Unguentum Resorcini et Bismuthi Compositum; Compound Resorcin and Bismuth Ointment.

	<i>Metric</i>	<i>Imperial</i>
Resorcinol	8.0 g.	140 gr.
Distilled Water	12.0 ml.	230½ m.
Zinc Oxide, finely sifted ..	8.0 g.	140 gr.
Bismuth Subchloride, finely sifted	8.0 g.	140 gr.
Birch Tar Oil	2.5 g.	43¾ gr.
Oil of Cade	2.5 g.	43¾ gr.
Starch, finely sifted	20.0 g.	350 gr.
Wool Fat	39.0 g.	1 oz. 245 gr.

Dissolve the resorcinol in the distilled water, and mix the solution with the bismuth subchloride, zinc oxide and starch to form a smooth cream; mix the birch tar oil and oil of cade with the wool fat, and gradually incorporate the cream.

UNGUENTUM ROSÆ ALBUM

(Ung. Ros. Alb.)

White Rose Ointment*Synonym*—Ceratum Galeni.

		<i>Metric</i>	<i>Imperial</i>
Triple Rose Water	25.0 ml.	1 fl. oz.
White Beeswax	10.0 g.	175 gr.
Spermaceti	10.0 g.	175 gr.
Oil of Rose	0.1 ml.	2 m.
Almond Oil	54.9 g.	2 oz. 85½ gr.

Add the rose water gradually, with constant stirring, to the white beeswax and spermaceti previously melted in the almond oil; then add the oil of rose, and continue stirring until cold.

UNGUENTUM RUBRI SCARLATINI

(Ung. Rub. Scarlat.)

Ointment of Scarlet Red*Synonym*—Unguentum Rubrum.

		<i>Metric</i>	<i>Imperial</i>
Scarlet Red, finely sifted	5 g.	87½ gr.
Simple Ointment	95 g.	3 oz. 350 gr.

Mix thoroughly by trituration.

UNGUENTUM RUSCI COMPOSITUM

(Ung. Rusc. Co.)

Compound Birch Tar Ointment

		<i>Metric</i>	<i>Imperial</i>
Birch Tar Oil	8 g.	140 gr.
Resorcinol, finely sifted	2 g.	35 gr.
Zinc Oxide, finely sifted	24 g.	420 gr.
Starch, finely sifted	24 g.	420 gr.
Hydrous Wool Fat	20 g.	350 gr.
White Soft Paraffin	22 g.	385 gr.

Mix the resorcinol with the zinc oxide and starch, incorporate with the previously mixed birch tar oil and hydrous wool fat, and then mix with the white soft paraffin.

UNGUENTUM SAMBUCI

(Ung. Sambuc.)

Elder Ointment

		<i>Metric</i>	<i>Imperial</i>
Triple Elder-flower Water	..	20.0 ml.	384 m.
Chlorophyll	0.5 g.	8 $\frac{1}{4}$ gr.
Simple Ointment, yellow	..	80.0 g.	3 oz. 87 $\frac{1}{2}$ gr.

Mix the chlorophyll with the melted simple ointment, gradually add the triple elder-flower water with constant trituration, and continue stirring until cold.

UNGUENTUM STAPHISAGRIÆ

(Ung. Staphisag.)

Stavesacre Ointment

		<i>Metric</i>	<i>Imperial</i>
Stavesacre	20 g.	350 gr.
Yellow Beeswax	10 g.	175 gr.
Benzoinated Lard	85 g.	3 oz. 175 gr.

Crush the stavesacre, and digest it in the benzoinated lard on a water-bath for two hours; strain through calico, melt the beeswax in the liquid mixture, and stir until cold.

UNGUENTUM STRAMONII

(Ung. Stramon.)

Stramonium Ointment

		<i>Metric</i>	<i>Imperial</i>
Extract of Stramonium	10 g.	175 gr.
Alcohol (45 per cent.)	5 ml.	96 m.
Hydrous Wool Fat	20 g.	350 gr.
Benzoinated Lard	65 g.	2 oz. 262 $\frac{1}{2}$ gr.

Triturate the extract of stramonium with the alcohol until smooth, and incorporate with the hydrous wool fat; add the benzoinated lard, and mix thoroughly.

In making this preparation the alcohol (45 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

UNGUENTUM SULPHURIS CAMPHORATUM**(Ung. Sulphur. Camph.)****Camphorated Sulphur Ointment**

	<i>Metric</i>	<i>Imperial</i>
Sublimed Sulphur, finely sifted	2 g.	35 gr.
Phenol	3 g.	52½ gr.
Resorcinol, finely sifted	3 g.	52½ gr.
Camphor	3 g.	52½ gr.
Solution of Coal Tar	5 g.	87½ gr.
Lard	42 g.	1 oz. 297½ gr.
White Soft Paraffin	42 g.	1 oz. 297½ gr.

Triturate the sulphur and resorcinol with a portion of the white soft paraffin until smooth, add the remainder of the white soft paraffin and the lard, and incorporate the phenol, camphor and solution of coal tar previously triturated together until liquefied.

UNGUENTUM SULPHURIS COMPOSITUM**(Ung. Sulphur. Co.)****Compound Sulphur Ointment**

	<i>Metric</i>	<i>Imperial</i>
Sublimed Sulphur, finely sifted	15 g.	¾ oz.
Calcium Carbonate	10 g.	½ oz.
Tar	15 g.	¾ oz.
Lard	30 g.	1½ oz.
Soft Soap	30 g.	1½ oz.

Mix thoroughly the sublimed sulphur and calcium carbonate with the lard and soft soap, and incorporate the tar.

UNGUENTUM SULPHURIS ET RESORCINOLIS**(Ung. Sulphur. et Resorcin.)****Sulphur and Resorcinol Ointment**

Synonyms—Unguentum Sulphuris et Resorcini; Sulphur and Resorcin Ointment.

	<i>Metric</i>	<i>Imperial</i>
Sublimed Sulphur, finely sifted	4.5 g.	78¾ gr.
Resorcinol, finely sifted	3.0 g.	52½ gr.
Yellow Soft Paraffin	92.5 g.	3 oz. 306¼ gr.

Mix.

UNGUENTUM SULPHURIS HYPOCHLORITIS

(Ung. Sulphur. Hypochlor.)

Sulphur Hypochlorite Ointment

	<i>Metric</i>	<i>Imperial</i>
Sublimed Sulphur, finely sifted	12 g.	210 gr.
Sulphur Chloride	2 g.	35 gr.
Oil of Bitter Almond without		
Hydrocyanic Acid	2 g.	35 gr.
Lard	84 g.	3 oz. 157½ gr.

Mix the sulphur with the lard and the oil of bitter almond, and rapidly incorporate the sulphur chloride.

It should be freshly prepared.

UNGUENTUM SULPHURIS IODIDI

(Ung. Sulphur. Iod.)

Sulphur Iodide Ointment

	<i>Metric</i>	<i>Imperial</i>
Sulphur Iodide	4 g.	70 gr.
Glycerin	4 g.	70 gr.
Simple Ointment, yellow ..	92 g.	3 oz. 297½ gr.

Triturate the sulphur iodide and the glycerin in a slightly warmed mortar until a smooth paste results, then gradually add the simple ointment and stir until cold.

UNGUENTUM TRINITROPHENOLIS

(Ung. Trinitrophen.)

Trinitrophenol Ointment

Synonyms—Unguentum Acidi Picrici; Picric Acid Ointment.

	<i>Metric</i>	<i>Imperial</i>
Trinitrophenol	2 g.	35 gr.
Distilled Water	2 ml.	38½ m.
Yellow Soft Paraffin	96 g.	3 oz. 367½ gr.

Triturate the trinitrophenol with the water and incorporate the soft paraffin.

UNGUENTUM VERATRINÆ

(Ung. Veratrin.)

Veratrine Ointment

	<i>Metric</i>	<i>Imperial</i>
Veratrine	2 g.	35 gr.
Oleic Acid	8 g.	140 gr.
Benzoinated Lard	90 g.	3 oz. 262½ gr.

Triturate the veratrine with the oleic acid, gently warm the mixture until the alkaloid is dissolved and mix with the benzoinated lard.

UNGUENTUM ZINCI CUM BALSAMO PERUVIANO

(Ung. Zinc. c. Bals. Peruv.)

Zinc Ointment with Balsam of Peru

	<i>Metric</i>	<i>Imperial</i>
Balsam of Peru	10 g.	½ oz.
Ointment of Zinc Oxide	40 g.	2 oz.
Ointment of Boric Acid	40 g.	2 oz.

Mix.

UNGUENTUM ZINCI CUM BENZOINO

(Ung. Zinc. c. Benzoin.)

Ointment of Zinc Oxide with Benzoin

	<i>Metric</i>	<i>Imperial</i>
Compound Tincture of Benzoin	10 ml.	½ fl. oz.
Ointment of Zinc Oxide	70 g.	3½ oz.

Mix.

In making this preparation the compound tincture of benzoin may be replaced by a compound tincture of benzoin prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

UNGUENTUM ZINCI ET OLEI RICINI

(Ung. Zinc. et Ol. Ricin.)

Zinc and Castor Oil Ointment

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	7.5 g.	131½ g.
Castor Oil	50.0 g.	2 oz.
Benzoinated Lard	42.5 g.	1 oz. 306½ gr.

Mix.

UNGUENTUM ZINCI ET OLEI RICINI CUM BENZOINO

(Ung. Zinc. et Ol. Ricin. c. Benzoin.)

Zinc and Castor Oil Ointment with Benzoin

	<i>Metric</i>	<i>Imperial</i>
Zinc Oxide	6 g.	116½ gr.
Castor Oil	40 g.	1 oz. 340 gr.
Compound Tincture of Benzoin	10 ml.	213 m.
Benzoinated Lard	34 g.	1 oz. 223½ gr.
Mix.		

In making this preparation the compound tincture of benzoin may be replaced by a compound tincture of benzoin prepared with industrial methylated spirit suitably diluted, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

The proportions of zinc oxide and benzoinated lard are equivalent to about 40 per cent. of the zinc ointment of the British Pharmacopœia, 1914.

UNGUENTUM ZINCI MORRHUATIS

(Ung. Zinc. Morr.)

Zinc Morrhuate Ointment

	<i>Metric</i>	<i>Imperial</i>
Cod-liver Oil	14.4 ml.	276½ m.
Zinc Oxide	32.0 g.	1 oz. 122½ gr.
Solution of Calcium Hydroxide	4.8 ml.	92 m.
Wool Fat	3.2 g.	56 gr.
White Soft Paraffin	19.2 g.	336 gr.
White Beeswax	12.8 g.	224 gr.
Purified Talc	12.8 g.	224 gr.
Balsam of Peru	0.8 ml.	15 m.

Mix the cod-liver oil with the solution of calcium hydroxide, triturate the mixture with the zinc oxide to a smooth cream, and set aside for twenty-four hours. Melt together the soft paraffin, beeswax and wool fat, and allow to cool; warm the zinc cream to about the same temperature, mix the two creams, and incorporate the purified talc and the balsam of peru.

VAPORES**Inhalations**

Inhalations are liquid preparations containing one or more volatile ingredients which, when inhaled in a suitable manner, are intended to act on the throat, lungs or nasal passages. They may be either dry

or moist inhalations. In dry inhalations, the medicaments are volatile at ordinary temperatures; they are usually directed to be placed on a sponge or absorbent pad in a specially designed oro-nasal respirator, and the vapour inhaled either continuously or at stated intervals. Moist inhalations generally contain volatile oils in an aqueous medium, and are intended to be added to hot water (about 150°F.) in an earthenware or other suitable vessel, and the vapour inhaled for five to ten minutes. The oils should not be suspended, but should be diffused in the medium by the addition of light magnesium carbonate, kaolin, or purified talc, and directions should be given for the bottle to be well shaken before use.

VAPOR CRESOLIS COMPOSITUS

(Vap. Cresol. Co.)

Compound Cresol Inhalation

				<i>Metric</i>	<i>Imperial</i>
Creosote	1 ml.	19 $\frac{1}{4}$ m.
Oil of Eucalyptus	2 ml.	38 $\frac{1}{2}$ m.
Oil of Siberian Fir	2 ml.	38 $\frac{1}{2}$ m.
Cresol	to 100 ml.	to 4 fl. oz
Mix.					

VAPOR EUCALYPTI COMPOSITUS

(Vap. Eucalyp. Co.)

Compound Eucalyptus Inhalation

Synonym—Anti-catarrhal Salts.

				<i>Metric</i>	<i>Imperial</i>
Phenol	16.50 g.	288 $\frac{3}{4}$ gr.
Oil of Eucalyptus	16.50 ml.	316 $\frac{3}{4}$ m.
Oil of Siberian Fir	8.25 ml.	158 $\frac{1}{2}$ m.
Strong Solution of Iodine	8.25 ml.	158 $\frac{1}{2}$ m.
Camphor	16.50 g.	288 $\frac{3}{4}$ gr.
Ammoniated Alcohol	34.00 ml.	1 oz. 172 $\frac{3}{4}$ m.

Dissolve the phenol, camphor and the oils in the ammoniated alcohol, and add the strong solution of iodine. Saturate pine sawdust or peat dust with the mixture, and preserve in glass-stoppered bottles.

In making this preparation the ammoniated alcohol may be replaced by an ammoniated alcohol prepared with industrial methylated spirit, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

VAPOR IODI ÆTHEREUS

(Vap. Iodi Æther.)

Ethereal Inhalation of Iodine

		<i>Metric</i>	<i>Imperial</i>
Ethereal Solution of Iodine	..	25.0 ml.	1 fl. oz.
Phenol	25.0 g.	1 fl. oz.
Creosote	12.5 ml.	$\frac{1}{2}$ fl. oz.
Alcohol (90 per cent.) to	100.0 ml.	to 4 fl. oz.

Mix.

Ethereal inhalation of iodine is used on the absorbent pad or sponge of an oro-nasal respirator inhaler. The quantity sufficient for one dry inhalation is 0.6 millilitre (10 minims).

In making this preparation the alcohol (90 per cent.) may be replaced by industrial methylated spirit diluted so as to be of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed.

VAPOR PHENOLIS COMPOSITUS

(Vap. Phenol. Co.)

Compound Phenol Inhalation

Synonyms—Vapor Acidi Carbolici Compositus; Compound Carbolic Acid Inhalation.

		<i>Metric</i>	<i>Imperial</i>
Creosote	1 ml.	19 $\frac{1}{4}$ m.
Oil of Eucalyptus	2 ml.	38 $\frac{1}{2}$ m.
Oil of Siberian Fir	2 ml.	38 $\frac{1}{2}$ m.
Liquefied Phenol to	100 ml.	to 4 fl. oz.

Mix.

VINUM ALOES

(Vin. Aloes)

Aloes Wine

		<i>Metric</i>	<i>Imperial</i>
Aloes, coarsely powdered	..	37.50 g.	$\frac{3}{4}$ oz.
Cardamom, bruised	4.57 g.	40 gr.
Ginger, coarsely powdered	4.57 g.	40 gr.
Sherry-type Wine	.. to	1000.00 ml.	to 20 fl. oz.

Macerate the aloes, cardamom and ginger in 1000 millilitres (20 fluid ounces) of the sherry-type wine for seven days, with occasional agitation, filter the liquid, and add sufficient sherry-type wine to produce the required volume.

Dose.—4 to 8 millilitres (1 to 2 fluid drachms).

VINUM ANTIMONIALE**(Vin. Antim.)****Antimonial Wine**

	<i>Metric</i>	<i>Imperial</i>
Potassium Antimonyltartrate ..	4 g.	35 gr.
Distilled Water, boiling ..	40 ml.	384 m.
Sherry-type Wine to 1000 ml.	to 20 fl. oz.

Dissolve the potassium antimonyltartrate in the distilled water, and add sufficient sherry-type wine to produce the required volume.

Dose.—0.6 to 2 millilitres (10 to 30 minims); as an emetic, 8 to 16 millilitres (2 to 4 fluid drachms).

VINUM COLCHICI**(Vin. Colch.)****Colchicum Wine**

	<i>Metric</i>	<i>Imperial</i>
Colchicum Corm, in moderately coarse powder ..	200 g.	4 oz.
Sherry-type Wine ..	1000 ml.	20 fl. oz.

Macerate the colchicum corm with the wine in a covered vessel for seven days, shaking occasionally, strain, press the marc, mix the two liquids, and clarify by subsidence or clarification.

Dose.—0.6 to 2 millilitres (10 to 30 minims).

VINUM COLCHICI SEMINIS**(Vin. Colch. Sem.)****Colchicum Seed Wine**

	<i>Metric</i>	<i>Imperial</i>
Colchicum Seed, in moderately coarse powder ..	100 g.	2 oz.
Detannated Sherry-type Wine ..	1000 ml.	20 fl. oz.

Macerate the colchicum seed with the wine in a covered vessel for seven days, shaking occasionally, strain, press the marc, mix the two liquids, and clarify by subsidence or clarification.

Dose.—0.6 to 2 millilitres (10 to 30 minims).

VINUM FERRI

(Vin. Ferr.)

Iron Wine

	<i>Metric</i>	<i>Imperial</i>
Iron	50 g.	1 oz.
Sherry-type Wine	1000 ml.	20 fl. oz.

Partially immerse the iron in the sherry-type wine in a closed vessel, and continue the maceration until the filtered liquid responds to the following test:—Evaporate 50 millilitres to dryness, incinerate the residue, heat the ash with hydrochloric acid diluted with an equal volume of distilled water, filter, wash the filter paper with distilled water, and add to the mixed filtrate and washings excess of solution of ammonia. Collect the precipitate, wash, dry and ignite; the residue weighs not less than 0.089 and not more than 0.215 gramme, representing a proportion of not less than 0.125 per cent. and not more than 0.300 per cent. w/v of Fe.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

VINUM FERRI CITRATIS

(Vin. Ferr. Cit.)

Iron Citrate Wine

	<i>Metric</i>	<i>Imperial</i>
Iron and Ammonium Citrate ..	18 g.	157½ gr.
Orange Wine to 1000 ml.	to 20 fl. oz.

Dissolve, shake occasionally for three days, and filter.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

VINUM FERRI ET QUININÆ

(Vin. Ferr. et Quinin.)

Iron and Quinine Wine

	<i>Metric</i>	<i>Imperial</i>
Iron and Quinine Citrate ..	20 g.	175 gr.
Sherry-type Wine	1000 ml.	20 fl. oz.

Add the iron and quinine citrate to the sherry-type wine, set aside for three days, shaking occasionally, and filter.

Dose.—4 to 16 millilitres (1 to 4 fluid drachms).

VINUM PEPSINI**(Vin. Pepsin.)****Pepsin Wine**

	<i>Metric</i>	<i>Imperial</i>
Pepsin	36·6 g.	320 gr.
Hydrochloric Acid	12·5 ml.	120 m.
Glycerin	50·0 ml.	1 fl. oz.
Detannated Sherry-type Wine	to 1000·0 ml.	to 20 fl. oz.

Triturate the pepsin with the glycerin, and add gradually, with constant stirring, a mixture of the hydrochloric acid and 900 millilitres (18 fluid ounces) of the sherry-type wine; set aside for seven days, filter, and add sufficient of the sherry-type wine to produce the required volume.

Dose.— 4 to 8 millilitres (1 to 2 fluid drachms).

VINUM QUININÆ**(Vin. Quinin.)****Quinine Wine**

	<i>Metric</i>	<i>Imperial</i>
Quinine Hydrochloride	2·3 g.	20 gr.
Orange Wine	1000·0 ml.	20 fl. oz.

Dissolve, and filter if necessary.

Dose.— 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce).

VINUM XERICUM DETANNATUM**(Vin. Xeric. Detann.)****Detannated Sherry-type Wine**

	<i>Metric</i>	<i>Imperial</i>
Sherry-type Wine	1000·0 ml.	20 fl. oz.
Gelatin, in fine powder	1·5 g.	13 gr.

Macerate for twenty-four hours, at a temperature not exceeding 15·5°, with frequent agitation, and afterwards decant.

APPENDIX III

Tables for the Dilution of Alcohol

The volumes of alcohol (95 per cent.) which must be diluted with distilled water in order to produce one litre of the various official dilute alcohols are given under Alcohol. When alcohol and water are mixed, contraction in volume and rise of temperature occur and it is important that before the final adjustment to volume is made the diluted alcohol should be allowed to cool to the same temperature, about 15°, as that at which the alcohol (95 per cent.) was measured. Owing to the large coefficients of expansion of alcohol and its dilutions, if this precaution as to cooling is neglected, errors will result and the actual alcoholic strength may differ considerably from that required.

When it is necessary to dilute alcohol of a strength other than 95 per cent., or in order to avoid the necessity for cooling, the alcohol strength of the diluted liquid may be ascertained from the specific gravity. When this method is adopted, the concentrated alcohol is diluted approximately to the required strength, the apparent strength is ascertained from the specific gravity determined by means of a hydrometer, a correction is applied for temperature when this exceeds 15·6°, and the liquid is adjusted as found necessary by the addition of stronger alcohol or of water. The necessary tables are given below. Table A gives specific gravities at 15·6° in the first column and the corresponding percentages of alcohol by volume in the second column. Table B gives the correction to be applied when the temperature of the diluted liquid is between 16° and 35°; the correction is subtracted from the apparent percentage read off from Table A.

The following example illustrates the use of the tables when applied to the preparation of approximately 1 litre of alcohol (45 per cent.):—

In accordance with the figures given under Alcohol, 474 millilitres of alcohol (95 per cent.) was diluted with water to 1 litre. The dilution had a specific gravity of 0·930, and a temperature of 29°. By reference to Table A, the apparent percentage by volume of alcohol corresponding to this gravity is 52·18. By reference to Table B, the error in an observed percentage of 52 at 29° is seen to be 5·04. The corrected strength is therefore 52·18 minus 5·04, or 47·1 per cent. Since the change in temperature and the contraction in volume are negligible in making the small final adjustment, alcohol (45 per cent.) may be made by diluting 450 millilitres of the above liquid to 471 millilitres with water; 1 litre must therefore be diluted with 46 millilitres of water. If desired, the result may be checked with the hydrometer. In the above example, after adding the 46 millilitres of water, the temperature was still 29°, and the specific gravity was 0·934. Hence, the apparent percentage by volume (from Table A) is 50·15; the correction (from Table B, by interpolation between the figures given for apparent percentages of 49 and 52) is 5·11; the corrected percentage by volume is therefore 45·04.

TABLE A

Ytterbium....	Yb	173·04
Yttrium	Y	88·92
Zinc	Zn	65·38
Zirconium ..	Zr	91·22

APPENDIX V

Molecular Weights

The following list contains molecular weights that are used frequently in analytical operations. A complete list of atomic weights is included separately, and the molecular weights are based upon these atomic weights, for which, $O = 16$, is taken as the standard. The list contains substances of the British Pharmacopœia and of the British Pharmaceutical Codex, and also some that are not official. In the case of a few compounds for which a definite formula cannot be established, a theoretical formula is given for information, and in the case of some compounds having water of crystallisation, the formula and molecular weight of the anhydrous compound are given also.

Acetaldehyde	C_2H_4O	44.03
Acetanilide	C_8H_9ON	135.07
Acetarsol	$C_8H_{10}O_5NaS$	275.00
Acetic Anhydride	$C_4H_6O_3$	102.05
Acetone	C_3H_6O	58.05
Acetophenone	C_8H_8O	120.06
Acid Acetic	$C_2H_4O_2$	60.03
Acid Acetylsalicylic	$C_9H_8O_4$	180.06
Acid Arsenic	$H_3AsO_4, \frac{1}{2}H_2O$	150.94
Acid Aurobromic	$HAuBr_4, 5H_2O$	607.95
Acid Aurochloric	$HAuCl_4, 4H_2O$	412.10
Acid Benzoic	$C_7H_6O_2$	122.05
Acid Boric	H_3BO_3	61.84
Acid Cacodylic	$C_2H_7O_2As$	137.96
Acid Camphoric	$C_{10}H_{16}O_4$	200.12
Acid Chloroplatinic	$H_2PtCl_6, 6H_2O$	518.08
Acid Cinnamic	$C_9H_8O_2$	148.06
Acid Citric	$C_6H_8O_7, H_2O$	210.08
Acid Formic	CH_2O_2	46.02
Acid Gallic	$C_7H_6O_5, H_2O$	188.06
Acid Glycerophosphoric	$C_3H_9O_6P$	172.09
Acid Hippuric	$C_9H_9O_3N$	179.08
Acid Hydriodic	HI	127.93
Acid Hydrobromic	HBr	80.92
Acid Hydrochloric	HCl	36.46
Acid Hydrocyanic	HCN	27.02
Acid Hydrofluoric	HF	20.01
Acid Hypophosphorous	H_3PO_2	66.04
Acid Lactic	$C_3H_6O_3$	90.05
Acid Malic	$C_4H_6O_5$	134.05
Acid Metaboric	HBO_2	43.83
Acid Nitric	HNO_3	63.02
Acid Nitrous	HNO_2	47.02

Molecular Weights—Continued.

Acid Oleic	$C_{18}H_{34}O_2$	282·27
Acid Oxalic	$C_2H_2O_4, 2H_2O$	126·05
Acid Oxalic (anhydrous)	$C_2H_2O_4$	90·02
Acid Phosphoric	H_3PO_4	98·04
Acid Phosphorous	H_3PO_3	82·04
Acid Pyroboric	$H_2B_4O_7$	157·30
Acid Salicylic	$C_7H_6O_3$	138·05
Acid Stearic	$C_{18}H_{36}O_2$	284·28
Acid Succinic	$C_4H_6O_4$	118·05
Acid Sulphanilic	$C_6H_7O_3NS, 2H_2O$	209·15
Acid Sulphuric	H_2SO_4	98·08
Acid Sulphurous	H_2SO_3	82·08
Acid Tartaric	$C_4H_6O_6$	150·05
Acid Trichloroacetic	$C_2HO_2Cl_3$	163·38
Acid Uric	$C_5H_4O_3N_3$	154·06
Acid Valeric	$C_5H_{10}O_2$	102·08
Aconitine	$C_{34}H_{47}O_{11}N$	645·37
Aconitine Hydrobromide	$C_{34}H_{47}O_{11}N, HBr, 2\frac{1}{2}H_2O$	771·34
Aconitine Hydrochloride	$C_{34}H_{47}O_{11}N, HCl, 3H_2O$	735·89
Aconitine Nitrate	$C_{34}H_{47}O_{11}N, HNO_3$	708·39
Acridine	$C_{14}H_{11}N_3Cl, HCl$	296·06
Adrenaline	$C_9H_{13}O_3N$	183·11
Alcohol, Amyl	$C_5H_{12}O$	88·09
Alcohol, Ethyl	C_2H_6O	46·05
Alcohol, Isopropyl	C_3H_8O	60·06
Alcohol, Methyl	CH_4O	32·03
Allantoin	$C_4H_6O_3N_4$	158·08
Allyl Isothiocyanate	C_4H_5NS	99·11
Allyl Sulphide	$C_6H_{10}S$	114·14
Aluminium Acetate	$(C_2H_3O_2)_6Al_2$	408·08
Aluminium Ammonium Sulphate	$NH_4Al(SO_4)_2, 12H_2O$	453·32
Aluminium Ammonium Sulphate (anhydrous)	$NH_4Al(SO_4)_2$	237·13
Aluminium Potassium Sulphate	$KAl(SO_4)_2, 12H_2O$	474·38
Aluminium Potassium Sulphate (anhydrous)	$KAl(SO_4)_2$	258·19
Aluminium Chloride	$AlCl_3, 6H_2O$	241·43
Aluminium Hydroxide	$Al(OH)_3$	78·00
Aluminium Oxide	Al_2O_3	101·94
Aluminium Sulphate	$Al_2(SO_4)_3, 16H_2O$	630·37
Aluminium Sulphate (anhydrous)	$Al_2(SO_4)_3$	342·12
Amidopyrine	$C_{13}H_{17}ON_3$	231·16
Ammonia	NH_3	17·03

Molecular Weights—Continued.

Ammonium Acetate	$C_2H_3O_2(NH_4)$	77·06
Ammonium Benzoate	$C_7H_5O_2(NH_4)$	139·08
Ammonium Bicarbonate	NH_4HCO_3	79·05
Ammonium Bromide	NH_4Br	97·96
Ammonium Carbamate	$N_2H_6CO_2$	78·06
Ammonium Carbonate (normal)	$(NH_4)_2CO_3$	96·08
Ammonium Chloride	NH_4Cl	53·50
Ammonium Chlorplatinat ..	$(NH_4)_2PtCl_6$	444·05
Ammonium Citrate	$C_6H_5O_7(NH_4)_3 \cdot H_2O$	261·18
Ammonium Hippurate	$C_9H_8O_3N(NH_4)$	196·11
Ammonium Iodide	NH_4I	144·96
Ammonium Nitrate	NH_4NO_3	80·05
Ammonium Oxalate	$C_2O_4(NH_4)_2 \cdot H_2O$	142·09
Ammonium Persulphate	$(NH_4)_2S_2O_8$	228·20
Ammonium Phosphate	$(NH_4)_2HPO_4$	132·11
Ammonium Salicylate	$C_7H_5O_3(NH_4)$	155·08
Ammonium Sulphate	$(NH_4)_2SO_4$	132·14
Ammonium Sulphide	$(NH_4)_2S$	68·14
Ammonium Tartrate	$C_4H_4O_6(NH_4)_2$	184·11
Ammonium Vanadate	NH_4VO_3	116·99
Amydricine Hydrochloride ..	$C_{16}H_{26}O_2N_2 \cdot HCl$	314·68
Amyl Acetate	$C_7H_{14}O_2$	130·11
Amyl Nitrite	$C_5H_{11}O_2N$	117·09
Amylene Hydrate	$C_5H_{12}O$	88·09
Amylocaine Hydrochloride ..	$C_{14}H_{21}O_2N \cdot HCl$	271·63
Anethole	$C_{10}H_{12}O$	148·09
Aniline	C_6H_7N	93·06
Antimonious Chloride	$SbCl_3$	228·13
Antimonious Oxide	Sb_2O_3	291·52
Antimonious Sulphide	Sb_2S_3	339·70
Apomorphine Hydrochloride ..	$C_{17}H_{17}O_2N \cdot HCl, \frac{1}{2}H_2O$	312·61
Arsenic Sulphide	As_2S_5	310·12
Arsenic Triiodide	AsI_3	455·67
Arsenic Trioxide	As_2O_3	197·82
Arsenous Sulphide	As_2S_3	246·00
Atropine	$C_{17}H_{23}O_3N$	289·19
Atropine Salicylate	$C_{17}H_{23}O_3N \cdot C_7H_6O_3$	427·23
Atropine Sulphate	$(C_{17}H_{23}O_3N)_2 \cdot H_2SO_4 \cdot H_2O$..	694·47
Barbitone	$C_8H_{12}O_3N_2$	184·11
Barbitone, Soluble	$C_8H_{11}O_3N_2Na$	206·10
Barium Carbonate	$BaCO_3$	197·36
Barium Chloride	$BaCl_2 \cdot 2H_2O$	244·31
Barium Chloride (anhydrous) ..	$BaCl_2$	208·27
Barium Hydroxide	$Ba(OH)_2 \cdot 8H_2O$	315·50
Barium Sulphate	$BaSO_4$	233·42

Molecular Weights—Continued.

Benzaldehyde.....	C_7H_6O	106.05
Benzamine Hydrochloride ..	$C_{15}H_{21}O_2N.HCl$	283.64
Benzamine Lactate	$C_{15}H_{21}O_2N.C_3H_5O_2$	337.22
Benzene	C_6H_6	78.05
Benzidine	$C_{12}H_{12}N_2$	184.11
Benzocaine	$C_9H_{11}O_2N$	165.09
Benzophenone	$C_{13}H_{10}O$	182.08
Benzyl Benzoate	$C_{14}H_{12}O_2$	212.09
Benzyl Succinate	$C_{18}H_{18}O_4$	298.14
Benzylmorphine	$C_{24}H_{25}O_3N$	375.20
Berberine	$C_{20}H_{19}O_5N$	353.16
Berberine Carbonate.....	$C_{20}H_{19}O_4N(HCO_2)_2.2H_2O$	433.19
Berberine Hydrochloride ..	$C_{20}H_{19}O_4NCl.2H_2O$	407.64
Berberine Phosphate.....	$C_{20}H_{18}O_4N(H_2PO_4)_2.H_3PO_4.1\frac{1}{2}H_2O$	558.25
Berberine Sulphate	$C_{20}H_{18}O_4N(HSO_4)_2$	433.22
Betanaphthol	$C_{10}H_8O$	144.06
Betanaphthyl Benzoate	$C_{17}H_{12}O_2$	248.09
Betanaphthyl Salicylate	$C_{17}H_{12}O_3$	264.09
Bismuth Carbonate	$(Bi_2O_3.CO_2)_2.H_2O$	1038.02
Bismuth Citrate.....	$C_6H_5O_7Bi$	398.04
Bismuth Hydroxide	$Bi(OH)_3$	260.02
Bismuth Naphtholate	$C_{10}H_8O_4Bi_2$	610.06
Bismuth Nitrate	$Bi(NO_3)_3.5H_2O$	485.10
Bismuth Phosphate	$BiPO_4$	304.02
Bismuth Salicylate	$C_7H_5O_3.BiO$	362.04
Bismuth Subchloride	$BiOCl$	260.46
Bismuth Subnitrate	$6Bi_2O_3.5N_2O_5.9H_2O$	3498.22
Bismuth Sulphide	Bi_2S_3	514.18
Bismuth Tartrate	$(C_4H_4O_6)_3Bi_2$	862.09
Bismuth Trioxide	Bi_2O_3	466.00
Borax	$Na_2B_4O_7.10H_2O$	381.43
Bordeaux B	$C_{20}H_{12}N_2O_7S_2Na_2$	502.22
Borneol	$C_{10}H_{18}O$	154.14
Bornyl Acetate.....	$C_{12}H_{20}O_2$	196.16
Boron Trioxide	B_2O_3	69.64
Brilliant Green	$C_{27}H_{34}O_4N_2S$	482.34
Bromoform	$CHBr_3$	252.76
Brucine	$C_{23}H_{26}O_4N_2.4H_2O$	466.28
Brucine (anhydrous).....	$C_{23}H_{26}O_4N_2$	394.22
Butylchloral Hydrate	$C_4H_7O_2Cl_3$	193.43
Cadmium Chloride	$CdCl_2.2H_2O$	219.36
Cadmium Iodide	CdI_2	366.27
Cadmium Sulphide.....	CdS	144.47
Caffeine	$C_8H_{10}O_2N_4.H_2O$	212.13
Caffeine (anhydrous)	$C_8H_{10}O_2N_4$	194.11

Molecular Weights—Continued.

Caffeine Citrate	$C_8H_{10}O_2N_4, C_6H_8O_7$	386·17
Caffeine Hydrobromide	$C_8H_{10}O_2N_4, HBr, 2H_2O$	311·07
Caffeine Iodide	$C_8H_{10}O_2N_4I_2, HI, H_2O$	593·89
Caffeine Salicylate	$C_8H_{10}O_2N_4, C_7H_6O_3$	332·16
Calcium Acetylsalicylate	$C_{18}H_{14}O_8Ca, 2H_2O$	434·22
Calcium Bromide	$CaBr_2, 2H_2O$	235·94
Calcium Carbonate	$CaCO_3$	100·08
Calcium Chloride	$CaCl_2, 6H_2O$	219·09
Calcium Chloride (anhydrous)	$CaCl_2$	110·99
Calcium Formate	$C_2H_2O_4Ca$	130·10
Calcium Glycerophosphate ..	$C_3H_7O_6PCa, 2H_2O$	246·19
Calcium Hydroxide	$Ca(OH)_2$	74·10
Calcium Hypophosphite	$Ca(PH_2O_2)_2$	170·15
Calcium Iodide	CaI_2	293·92
Calcium Lactate	$C_6H_{10}O_6Ca, 5H_2O$	308·24
Calcium Lactate (anhydrous)	$C_6H_{10}O_6Ca$	218·16
Calcium Oxalate	C_2O_4Ca	128·08
Calcium Oxide	CaO	56·08
Calcium Permanganate	$CaMn_2O_8, 5H_2O$	368·02
Calcium Phosphate	$Ca_3(PO_4)_2$	310·28
Calcium Sodiumlactate	$C_{12}H_{20}O_{12}CaNa_2, 4H_2O$	514·29
Calcium Sulphate	$CaSO_4, 2H_2O$	172·17
Calcium Sulphate (anhydrous)	$CaSO_4$	136·14
Calcium Sulphide	CaS	72·14
Camphor	$C_{10}H_{16}O$	152·12
Camphor Monobromide	$C_{10}H_{15}OBr$	231·03
Cantharidin	$C_{10}H_{12}O_4$	196·09
Carbon Dioxide	CO_2	44·00
Carbon Disulphide	CS_2	76·12
Carbon Tetrachloride	CCl_4	153·83
Carbromal	$C_7H_{13}O_2N_2Br$	237·03
Carvone	$C_{10}H_{14}O$	150·11
Cerium Oxalate (anhydrous) ..	$(C_2O_4)_3Ce_2$	544·26
Chloral	C_2HOCl_3	147·38
Chloral Hydrate	C_2HOCl_3, H_2O	165·39
Chloral Formamide	$C_3H_4O_2NCl_3$	192·41
Chloramine	$C_7H_7O_2NCISNa, 3H_2O$	281·62
Chlorbutol	$C_4H_7OCl_3$	177·43
Chloroform	$CHCl_3$	119·38
Chrome Alum	$KCr(SO_4)_2, 12H_2O$	499·42
Chromium Oxide	Cr_2O_3	152·02
Chromium Trioxide	CrO_3	100·01
Cinchonidine	$C_{19}H_{22}ON_2$	294·19
Cinchonidine Dihydrochloride ..	$C_{19}H_{22}ON_2, 2HCl$	367·11
Cinchonidine Hydrochloride ..	$C_{19}H_{22}ON_2, HCl$	330·65
Cinchonidine Salicylate	$C_{19}H_{22}ON_2, C_7H_6O_3$	432·23

Molecular Weights—Continued.

Cinchonidine Sulphate	$(C_{19}H_{22}ON_2)_2, H_2SO_4, 7H_2O$	812.56
Cinchonine	$C_{19}H_{23}ON_2$	294.19
Cinchonine Dihydrochloride	$C_{19}H_{22}ON_2, 2HCl$	367.11
Cinchonine Hydrochloride	$C_{19}H_{22}ON_2, HCl, 2H_2O$	366.68
Cinchonine Sulphate	$(C_{19}H_{22}ON_2)_2, H_2SO_4, 2H_2O$	722.48
Cinchophen	$C_{16}H_{11}O_2N$	249.09
Cinnamic Aldehyde	C_9H_8O	132.06
Citral	$C_{10}H_{16}O$	152.12
Cobalt Nitrate	$Co(NO_3)_2, 6H_2O$	291.05
Cobalt Nitrate (anhydrous)	$Co(NO_3)_2$	182.96
Cocaine	$C_{17}H_{21}O_4N$	303.17
Cocaine Hydrochloride	$C_{17}H_{21}O_4N, HCl$	339.63
Cocaine Nitrate	$C_{17}H_{21}O_4N, HNO_3$	366.19
Codeine	$C_{18}H_{21}O_3N, H_2O$	317.19
Codeine (anhydrous)	$C_{18}H_{21}O_3N$	299.17
Codeine Hydrochloride	$C_{18}H_{21}O_3N, HCl, 2H_2O$	371.67
Codeine Phosphate	$C_{18}H_{21}O_3N, H_3PO_4, H_2O$	415.23
Codeine Phosphate (anhydrous)	$C_{18}H_{21}O_3N, H_3PO_4$	397.21
Codeine Sulphate	$(C_{18}H_{21}O_3N)_2, H_2SO_4, 5H_2O$	786.50
Codeine Sulphate (anhydrous)	$(C_{18}H_{21}O_3N)_2, H_2SO_4$	696.42
Colchicine	$C_{22}H_{25}O_6N$	399.20
Colchicine Salicylate	$C_{22}H_{25}O_6N, C_7H_6O_3$	537.25
Coniine	$C_8H_{17}N$	127.14
Coniine Hydrobromide	$C_8H_{17}N, HBr$	208.06
Coniine Hydrochloride	$C_8H_{17}N, HCl$	163.60
Copper Nitrate	$Cu(NO_3)_2, 3H_2O$	241.63
Copper Sulphate	$CuSO_4, 5H_2O$	249.71
Copper Sulphate (anhydrous)	$CuSO_4$	159.63
Copper Sulphide	CuS	95.63
Cotarnine	$C_{12}H_{15}O_4N$	237.13
Cotarnine Chloride	$C_{12}H_{14}O_3NCl, 2H_2O$	291.61
Coumarin	$C_9H_6O_2$	146.05
Creosol	$C_8H_{10}O_2$	138.08
Cresol	C_7H_8O	108.06
Dextrose	$C_6H_{12}O_6$	180.09
Diamorphine	$C_{21}H_{23}O_5N$	369.19
Diamorphine Hydrochloride	$C_{21}H_{23}O_5N, HCl, H_2O$	423.67
Dichloramine	$C_7H_7O_2NCl_2S$	240.04
Dichlorobenzene	$C_6H_4Cl_2$	146.95
Dichlorethylene	$C_2H_2Cl_2$	96.93
Dipentene	$C_{10}H_{16}$	136.12
Emetine	$C_{29}H_{40}O_4N_2$	480.33
Emetine Hydrobromide	$C_{29}H_{40}O_4N_2, 2HBr, 4H_2O$	714.24
Emetine Hydrochloride	$C_{29}H_{40}O_4N_2, 2HCl, 7H_2O$	679.37
Ephedrine	$C_{10}H_{15}ON$	165.13

Molecular Weights—Continued.

Ephedrine Hydrochloride....	$C_{10}H_{15}ON, HCl$	201.59
Ephedrine Sulphate	$(C_{10}H_{15}ON)_2, H_2SO_4$	428.33
Erythrityl Tetranitrate	$C_4H_6(NO_3)_4$	302.08
Ether.....	$C_4H_{10}O$	74.08
Ethyl Acetate	$C_4H_8O_2$	88.06
Ethyl Bromide	C_2H_5Br	108.96
Ethyl Chloride.....	C_2H_5Cl	64.50
Ethyl Iodide	C_2H_5I	155.96
Ethyl Nitrite	$C_2H_5O_2N$	75.05
Ethylene	C_2H_4	28.03
Ethylene Dibromide	$C_2H_4Br_2$	187.86
Ethylene Dichloride	$C_2H_4Cl_2$	98.95
Ethylhydrocupreine	$C_{21}H_{28}O_2N_2$	340.23
Ethylhydrocupreine Hydrochloride	$C_{21}H_{28}O_2N_2, HCl$	376.70
Ethylmorphine Hydrochloride	$C_{16}H_{23}O_3N, HCl, 2H_2O$	385.68
Eucalyptol	$C_{10}H_{18}O$	154.14

Sodium Potassium Tartrate	$C_4H_4O_6NaK, 4H_2O$	282.19
Sodium Pyrophosphate	$Na_4P_2O_7, 10H_2O$	446.18
Sodium Pyrophosphate (an- hydrous)	$Na_4P_2O_7$	266.03
Sodium Pyrosulphite	$Na_2S_2O_5$	190.11
Sodium Salicylate	$C_7H_5O_3Na$	160.04
Sodium Silicofluoride	Na_2SiF_6	188.05
Sodium Sulphate	$Na_2SO_4, 10H_2O$	322.21
Sodium Sulphate (anhydrous)	Na_2SO_4	142.05

Molecular Weights—Continued.

Sodium Sulphite	$\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$	252·16
Sodium Sulphite (anhydrous)	Na_2SO_3	126·05
Sodium Tartrate	$\text{C}_4\text{H}_4\text{O}_6\text{Na}_2 \cdot 2\text{H}_2\text{O}$	230·06
Sodium Tartrate (anhydrous)	$\text{C}_4\text{H}_4\text{O}_6\text{Na}_2$	194·03
Sodium Thiosulphate	$\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$	248·19
Sodium Thiosulphate (an- hydrous)	$\text{Na}_2\text{S}_2\text{O}_3$	158·11
Sparteine	$\text{C}_{15}\text{H}_{26}\text{N}_2$	234·22
Sparteine Sulphate	$\text{C}_{15}\text{H}_{26}\text{N}_2 \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$	422·38
Sparteine Sulphate (an- hydrous)	$\text{C}_{15}\text{H}_{26}\text{N}_2 \cdot \text{H}_2\text{SO}_4$	332·30
Stannic Oxide	SnO_2	150·70
Stannous Chloride	$\text{SnCl}_2 \cdot 2\text{H}_2\text{O}$	225·65
Stannous Chloride (anhydrous)	SnCl_2	189·61
Stannous Sulphide	SnS	150·76
Strontium Bromide	$\text{SrBr}_2 \cdot 6\text{H}_2\text{O}$	355·56
Strontium Carbonate	SrCO_3	147·63
Strontium Chloride	$\text{SrCl}_2 \cdot 6\text{H}_2\text{O}$	266·64
Strontium Iodide	$\text{SrI}_2 \cdot 6\text{H}_2\text{O}$	449·59
Strychnine	$\text{C}_{21}\text{H}_{22}\text{O}_2\text{N}_2$	334·19
Strychnine Acid Sulphate	$\text{C}_{21}\text{H}_{22}\text{O}_2\text{N}_2 \cdot \text{H}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$	468·30
Strychnine Hydrochloride	$\text{C}_{21}\text{H}_{22}\text{O}_2\text{N}_2 \cdot \text{HCl} \cdot 2\text{H}_2\text{O}$	406·68
Strychnine Sulphate	$(\text{C}_{21}\text{H}_{22}\text{O}_2\text{N}_2)_2 \cdot \text{H}_2\text{SO}_4 \cdot 5\text{H}_2\text{O}$..	856·53
Sucrose	$\text{C}_{12}\text{H}_{22}\text{O}_{11}$	342·17
Sulphonal	$\text{C}_7\text{H}_{16}\text{O}_4\text{S}_2$	228·24
Sulphur Dioxide	SO_2	64·06
Sulphur Trioxide	SO_3	80·06
Terpineol	$\text{C}_{10}\text{H}_{18}\text{O}$	154·14
Terpin Hydrate	$\text{C}_{10}\text{H}_{20}\text{O}_2 \cdot \text{H}_2\text{O}$	190·17
Terpinol	$\text{C}_{10}\text{H}_{16}$	136·12
Tetrachlorethane	$\text{C}_2\text{H}_2\text{Cl}_4$	167·84
Tetrachlorethylene	C_2Cl_4	165·83
Thallium Acetate	$\text{C}_2\text{H}_3\text{O}_2\text{Ti}$	263·41
Theobromine	$\text{C}_7\text{H}_8\text{O}_2\text{N}_4$	180·09
Theophylline	$\text{C}_7\text{H}_8\text{O}_2\text{N}_4 \cdot \text{H}_2\text{O}$	198·11
Thiosinamine	$\text{C}_4\text{H}_8\text{N}_2\text{S}$	116·14
Thymol	$\text{C}_{10}\text{H}_{14}\text{O}$	150·11
Thymol Iodide	$\text{C}_{20}\text{H}_{24}\text{O}_2\text{I}_2$	550·03
Thyroxine-sodium	$\text{C}_{15}\text{H}_{10}\text{O}_4\text{NI}_4\text{Na}$	798·81
Toluene	C_7H_8	92·06
Trichlorethylene	C_2HCl_3	131·38
Trinitrophenol	$\text{C}_6\text{H}_3\text{O}_7\text{N}_3$	229·05
Uranium Nitrate	$\text{UO}_2(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$	502·25
Urea	CH_4ON_2	60·05
Urethane	$\text{C}_3\text{H}_7\text{O}_2\text{N}$	89·06
Vanillin	$\text{C}_8\text{H}_8\text{O}_3$	152·06

Molecular Weights—Continued.

Water	H_2O	18·0156
Xylene	C_8H_{10}	106·08
Yohimbine	$\text{C}_{21}\text{H}_{26}\text{O}_3\text{N}_2$	354·22
Yohimbine Hydrochloride ..	$\text{C}_{21}\text{H}_{26}\text{O}_3\text{N}_2\cdot\text{HCl}$	390·68
Zinc Acetate	$\text{C}_4\text{H}_6\text{O}_4\text{Zn}\cdot 2\text{H}_2\text{O}$	219·46
Zinc Acetate (anhydrous)...	$\text{C}_4\text{H}_6\text{O}_4\text{Zn}$	183·43
Zinc Bromide	ZnBr_2	225·21
Zinc Carbonate	ZnCO_3	125·38
Zinc Chloride	ZnCl_2	136·29
Zinc Iodide	ZnI_2	319·22
Zinc Oxide	ZnO	81·38
Zinc Permanganate	$\text{ZnMn}_2\text{O}_8\cdot 6\text{H}_2\text{O}$	411·33
Zinc Phenolsulphonate	$\text{C}_{12}\text{H}_{10}\text{O}_8\text{S}_2\text{Zn}\cdot 8\text{H}_2\text{O}$	555·70
Zinc Phenolsulphonate (an- hydrous)	$\text{C}_{12}\text{H}_{10}\text{O}_8\text{S}_2\text{Zn}$	411·58
Zinc Phosphide	Zn_3P_2	258·18
Zinc Sulphate	$\text{ZnSO}_4\cdot 7\text{H}_2\text{O}$	287·55
Zinc Sulphate (anhydrous)...	ZnSO_4	161·44
Zinc Sulphide	ZnS	97·44
Zinc Valerianate	$\text{C}_{10}\text{H}_{18}\text{O}_4\text{Zn}\cdot 2\text{H}_2\text{O}$	303·55

APPENDIX VI

Reagents

In the following list are given the strengths of reagent solutions in frequent use in testing the substances of the British Pharmaceutical Codex, together with reagents not included in the British Pharmacopœia and for which the strength is not prescribed in the test. The list includes also a number of other reagents or substances which are in fairly frequent use either as diagnostic reagents or in clinical testing generally.

Unless expressly stated otherwise, dehydrated alcohol, alcohol (95 per cent.), or the dilute alcohols, when required in any tests or assays, or in the preparation of reagent solutions, may be replaced by industrial methylated spirit of equivalent alcoholic strength, provided that the law and the statutory regulations governing the use of industrial methylated spirit are observed. Industrial methylated spirit must not be used for solubility tests.

Acetic Acid: approximately 33 per cent. w/w of $\text{CH}_3\cdot\text{COOH}$ in water.

Acetic Acid, Dilute: approximately 6 per cent. w/w of $\text{CH}_3\cdot\text{COOH}$ in water.

Albumen Solution: a solution of the liquid white of fresh eggs in water.

Alcohol (90 per cent.): alcohol (90 per cent.; s.g. 0.832 to 0.835).

Alkali Blue Solution: a 0.1 per cent. w/v solution of alkali blue (a mixture of the sodium sulphonates of phenylated rosaniline and pararosaniline) in alcohol (90 per cent.); colour change, from blue to red with strong alkali in alcoholic solution.

Alkanna, Tincture of: 1 part by weight of alkanna extracted by maceration with 5 parts by volume of alcohol (90 per cent.).

Alum Solution: 5 per cent. w/v of potash alum or ammonia alum in water.

Ammonia Solution, 2N: an aqueous dilution of strong solution of ammonia containing in 1000 millilitres 34.06 grammes of NH_3 .

Ammonia Solution, Dilute: approximately 10 per cent. w/v of NH_3 in water.

Ammonium Acetate Solution: 5 per cent. w/v of ammonium acetate in water.

Ammonium Carbonate Solution: 5 per cent. w/v of ammonium carbonate with 7.5 per cent. v/v of dilute ammonia solution in water.

Ammonium Chloride Solution: 10 per cent. w/v of ammonium chloride in water.

Reagents—Continued.

Ammonium Chloride Solution (Nessler's): 0.315 per cent. w/v of ammonium chloride in ammonia-free water.

Ammonium Chloride Solution (Nessler's), Dilute: a 1 in 100 dilution of ammonium chloride solution (Nessler's) in ammonia-free water.

Ammonium Hydrosulphide Solution: 60 per cent. v/v of dilute ammonia solution saturated with washed hydrogen sulphide, with 40 per cent. v/v of dilute ammonia solution; it should be recently prepared.

Ammonium Molybdate Solution: 10 per cent. w/v of ammonium molybdate in water.

Ammonium Oxalate Solution: 2.5 per cent. w/v of ammonium oxalate in water.

Ammonium Phosphate Solution: 10 per cent. w/v of ammonium phosphate in water.

Ammonium Thiocyanate Solution: 10 per cent. w/v of ammonium thiocyanate in water.

Ammonium Thiocyanate Solution, N/10: an aqueous solution of ammonium thiocyanate containing in 1000 millilitres 7.611 grammes of NH_4SCN .

Aniline Hydrochloride Solution: a freshly prepared 2 per cent. w/v solution of aniline hydrochloride in 58.5 per cent. alcohol with 2 per cent. w/v of hydrochloric acid.

Auric Chloride Solution: 2 per cent. w/v of gold chloride, $\text{NaAuCl}_4 \cdot 2\text{H}_2\text{O}$, in water.

Azur-Eosin Solution: *Synonym.*—Giemsa's Stain: 3 grammes of azur II-eosin and 0.8 gramme of azur II dissolved in a mixture of 250 millilitres of glycerin and 250 millilitres of methyl alcohol.

Barium Chloride Solution: 10 per cent. w/v of barium chloride in water.

Barium Hydroxide Solution: 3 per cent. w/v of barium hydroxide, $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$, in water.

Barium Nitrate Solution: 10 per cent. w/v of barium nitrate in water.

Benzidine Solution: 1 per cent. w/v of benzidine (*p*-diaminodiphenyl, $\text{NH}_2\text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4\text{NH}_2$) in alcohol (90 per cent.).

Benzidine Solution, Acetic: a freshly prepared saturated solution of benzidine in glacial acetic acid.

Benzidine Solution, Alcoholic: a saturated solution of benzidine in alcohol (95 per cent.).

Blood Diluting Solution: *Synonym.*—Gower's Hæmocytometer Solution: 5.42 grammes of sodium sulphate in a mixture of 3.125 grammes of acetic acid and 1000 millilitres of water.

Reagents—Continued.

Blood Diluting Solution: *Synonym.*—Hayem's Solution: 10 grammes of sodium chloride, 25 grammes of sodium sulphate and 2·5 grammes of mercuric chloride in water to 1000 millilitres.

Blood Diluting Solution: *Synonym.*—Toison's Solution: 1 gramme of sodium chloride and 8 grammes of sodium sulphate in 80 millilitres of water added to a solution of 0·025 gramme of methyl violet in a mixture of 30 millilitres of glycerin and 80 millilitres of water. Filter immediately before use.

Bromine Solution: a saturated solution of bromine in water.

Bromine Solution, N/10: 3 grammes of potassium bromate and 50 grammes of potassium bromide in water to produce 1000 millilitres, and adjusted so that 1000 millilitres, acidified, yields 7·992 grammes of Br.

Bromocresol Green Solution: 0·1 gramme of bromocresol green (tetrabromo-*m*-cresolsulphonephthalein) warmed with 2·9 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 3·6 to 5·2. Colour change, yellow in acid solutions to blue-violet in weakly acid and alkaline solutions.

Bromocresol Purple Solution: 0·1 gramme of bromocresol purple (dibromo-*o*-cresolsulphonephthalein) warmed with 3·7 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 5·2 to 6·8. Colour change, yellow in acid solutions to purple in neutral or alkaline solutions.

Bromophenol Blue Solution: 0·1 gramme of bromophenol blue (tetrabromophenolsulphonephthalein) warmed with 3 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 2·8 to 4·6. Colour change, yellow in acid solutions to blue-violet in weakly acid and alkaline solutions.

Bromothymol Blue Solution: 0·1 gramme of bromothymol blue (dibromothymolsulphonephthalein) warmed with 3·2 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 6·0 to 7·6. Colour change, yellow in acid solutions, green indicating neutrality, to blue in alkaline solutions.

Cadmium Iodide Solution: 5 per cent. w/v of cadmium iodide in water.

Calcium Chloride Solution: 10 per cent. w/v of calcium chloride, $\text{CaCl}_2 \cdot 6\text{H}_2\text{O}$, in water.

Calcium Hydroxide Solution: a saturated solution of calcium hydroxide in water.

Reagents—Continued.

Calcium Sulphate Solution: a saturated solution of calcium sulphate in water.

Carbol-Fuchsin Solution: 1 gramme of magenta dissolved in 10 millilitres of dehydrated alcohol and mixed with 5 grammes of phenol dissolved in 90 millilitres of distilled water, and filtered.

Carbol-Gentian Violet Solution: 1 gramme of methyl violet and 5 grammes of phenol dissolved in 5 grammes of dehydrated alcohol and 100 millilitres of water.

Carbol-Thionine Blue Solution: 0.25 gramme of thionine blue dissolved in 10 millilitres of dehydrated alcohol and mixed with 0.6 gramme of phenol dissolved in 100 millilitres of water.

Chloral Hydrate and Glycerin: 12 grammes of chloral hydrate dissolved in 10 millilitres of glycerin.

Chloral Hydrate Solution: 50 grammes of chloral hydrate dissolved in 20 millilitres of water.

Chloral Hydrate with Iodine Solution: 50 grammes of chloral hydrate dissolved in 20 millilitres of water in contact with excess of iodine.

Chlorinated Lime Solution: 10 per cent. of chlorinated lime in water, shaken occasionally for three hours and filtered through calico.

Chlorinated Soda Solution: 150 grammes of sodium carbonate in 250 millilitres of water mixed with 100 grammes of chlorinated lime triturated with 750 millilitres of water, shaken occasionally during three hours, and filtered.

Chlor-Zinc-Iodine Solution: *Synonym.*—Schulze's Solution. 100 millilitres of solution of zinc chloride evaporated to 70 millilitres, 10 grammes of potassium iodide dissolved in the residue and 0.2 gramme of iodine shaken with this solution in a stoppered bottle until the solution is saturated with iodine.

Chromic Acid Solution: 25 per cent. w/v of chromium trioxide in water.

Chromic and Nitric Acids Solution: 10 grammes of chromium trioxide and 10 millilitres of nitric acid in water sufficient to produce 100 millilitres.

Cobalt Nitrate Solution: 10 per cent. w/v of cobalt nitrate in water.

Cochineal, Tincture of: macerate 1 part of crushed cochineal with 10 parts of alcohol (45 per cent.). pH range, 5 to 6. Colour change, brownish-yellow in acid solution to purple in weakly acid and alkaline solutions.

Congo-red: sodium diphenylbisazobisnaphthylamine-4-sulphonate. pH range, 3 to 5. Colour change, blue in moderately acid solutions to red in weakly acid and alkaline solutions.

Reagents—Continued.

Copper Acetate Solution, Dilute: 0.05 per cent. w/v of copper acetate in water.

Copper Acetate Solution, Strong: 5 per cent. w/v of copper acetate in water.

Copper Oxide Solution, Ammoniacal: freshly prepared by occasionally shaking, during twelve hours, 5 grammes of copper carbonate with 100 millilitres of strong ammonia solution, setting aside for twenty-four hours, and pouring off the clear liquid.

Copper Solution, Alkaline: (for the determination of blood sugar by MacLean's method): 30 grammes of potassium bicarbonate is dissolved in about 200 millilitres of distilled water with the aid of gentle heat (not above 37°) and 20 grammes of anhydrous potassium carbonate added, followed by a solution of 0.875 gramme of copper sulphate dissolved in a few millilitres of water; the liquid is warmed until effervescence ceases and the potassium carbonate is dissolved, when 0.125 gramme of potassium iodate and 1.25 grammes of potassium iodide are added and distilled water to 250 millilitres. It is used in conjunction with solution of dialysed iron, acid sodium sulphate solution, N/400 sodium thiosulphate, solution of sulphuric acid, 25 per cent. v/v, and solution of soluble starch, 1 per cent. w/v.

Copper Sulphate Solution: 10 per cent. w/v of copper sulphate in water.

Corallin Solution, Alkaline: *Synonym.*—Corallin-Soda: freshly prepared by dissolving 30 grammes of sodium carbonate in 70 millilitres of water, adding a small quantity of corallin (the sodium derivative of rosolic acid), and shaking.

Cotton Blue and Lactophenol Solution: 1 gramme of cotton blue added to a solution of 50 grammes of phenol in a mixture of 50 millilitres of lactic acid, 50 millilitres of glycerin and 50 millilitres of water; the mixture is allowed to stand and the clear liquid used.

Cresol Red Solution: 0.05 gramme of cresol red (*o*-cresolsulphonaphthalein) warmed with 2.65 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 7.2 to 8.8. Colour change, yellow in acid or neutral solutions to red in alkaline solutions.

Cuprous Chloride Solution, Acid: 20 per cent. w/v of cuprous chloride in hydrochloric acid.

Dextrose-Pyridine Solution, Alkaline: *Synonym.*—Takayama's Solution (for the microscopical detection of blood stains): a mixture of 3 millilitres of 10 per cent. w/v aqueous solution of sodium hydroxide, 3 millilitres of pyridine, 3 millilitres of a saturated aqueous solution of dextrose and 7 millilitres of distilled water.

Reagents—Continued.

Diazo Test Solution: *Synonym.*—Ehrlich's Diazo Reagent (for the testing of urine in the diagnosis of typhoid fever and other diseases).

(A) 0·1 gramme of sulphanilic acid dissolved in a mixture of 5 millilitres of hydrochloric acid and 95 millilitres of water.

(B) 0·5 gramme of sodium nitrite dissolved in water to 100 millilitres. For use, mix 50 parts by volume of A with 1 part by volume of B.

Dimethylaminobenzaldehyde Solution: *Synonym.* — Ehrlich's Aldehyde Reagent (for the detection of urobilin): 2 grammes of *p*-dimethylaminobenzaldehyde dissolved in a mixture of equal volumes of hydrochloric acid and water to 100 millilitres.

Dimethylaminobenzaldehyde Solution: *Synonym.*—Töpfer's Reagent (for the detection of free hydrochloric acid in gastric contents): 0·5 gramme of *p*-dimethylaminobenzaldehyde in alcohol (95 per cent.) to 100 millilitres.

Dimethyl Yellow Solution: 0·2 per cent. w/v of dimethyl yellow (dimethylaminoazobenzene) in alcohol (90 per cent.). *pH* range, 2·8 to 4. Colour change, red in moderately acid solutions to yellow in weakly acid and alkaline solutions.

Diphenylamine Solution: 1 per cent. w/v of diphenylamine in nitrogen-free sulphuric acid. It gives a blue colour with nitric acid and other oxidising agents. When used as an indicator in the titration of ferrous salts with potassium dichromate the colour change is from bluish-green to dark blue when oxidation is complete.

Egg Medium: *Synonym.*—Dorset's Egg Medium: twelve fresh eggs are washed externally with water and then with solution of formaldehyde, and allowed to dry. The eggs are broken into a sterile cylinder and to 3 volumes of the mixed whites and yolks is added 1 volume of sterilised physiological solution of sodium chloride. The mixture is whisked in a sterile vessel, filtered through muslin, mixed, if desired, with a few drops of an alcoholic solution of magenta, transferred to tubes and heated at 75° for one hour. The tubes are incubated before use and any found to be contaminated are rejected.

Eosin Solution, Alcoholic: 1 gramme of eosin in a mixture of 30 millilitres of water and 70 millilitres of alcohol (95 per cent.).

Eosin Solution, Aqueous: 1 gramme of eosin in 100 millilitres of water.

Ether-Alcohol: a mixture of equal volumes of ether and alcohol (95 per cent.).

Ferric Ammonium Sulphate Solution: 10 per cent. w/v of ferric ammonium sulphate in water. It gives a deep red colour with ammonium thiocyanate.

Reagents—Continued.

Ferric Ammonium Sulphate Solution, N/10: an aqueous solution of ferric ammonium sulphate containing in 1000 millilitres ferric iron equivalent to 5.584 grammes of Fe.

Ferric Chloride Solution: 15 per cent. w/v of anhydrous ferric chloride, FeCl_3 , in water.

Ferric Chloride Solution, Acid: *Synonym.*—Obermayer's Reagent (for the detection of indican): 1 gramme of ferric chloride in 500 millilitres of hydrochloric acid.

Ferrous Sulphate Solution, Acid: freshly prepared by dissolving 7 grammes of ferrous sulphate in 90 millilitres of freshly boiled and cooled water and adding sulphuric acid to 100 millilitres.

Ferrous Tartrate Solution: *Synonym.*—Mitchel's Reagent: 0.1 per cent. w/v of ferrous sulphate and 0.5 per cent. w/v of sodium potassium tartrate in water.

Gentian Violet in Aniline Water: 10 millilitres of saturated alcoholic solution of methyl violet mixed with 90 millilitres of water saturated with aniline.

Glucose-Agar Medium: 20 grammes of shredded agar dissolved with the aid of heat in 1000 millilitres of glucose broth. Sterilise by heating in an autoclave.

Glucose Broth: 20 grammes of dextrose in 1000 millilitres of nutrient broth. Sterilise by heating in an autoclave.

Glycerin, Dilute: 1 volume of glycerin mixed with 2 volumes of water.

Hæmatoxylin Solution: 1 per cent. w/v of hæmatoxylin in alcohol (60 per cent.). Colour change, yellow in moderately acid solutions to green or purple in weakly acid and alkaline solutions.

Hydrochloric Acid, Dilute: approximately 10 per cent. w/v of HCl in water.

Hydrochloric Acid, N/1: an aqueous solution of hydrochloric acid containing in 1000 millilitres 36.46 grammes of HCl

Hydrochloric Acid PbT.: dilute hydrochloric acid with water until it contains from 25 to 27 per cent. of HCl. The solution complies with the B.P. test for dilute hydrochloric acid PbT., using 20 millilitres of reagent.

Hydrogen Sulphide Solution: recently prepared by saturating water with hydrogen sulphide.

Hypophosphorous Acid, Dilute: approximately 10 per cent. w/w of H_2PO_3 in water.

Reagents—Continued.

Indigo Carmine Solution: a solution of indigo carmine (about 0·03 per cent w/v) in 20 per cent. w/v solution of nitrogen-free sulphuric acid, adjusted so that 10 millilitres is decolourised by a solution of 0·001 gramme of potassium nitrate in 10 millilitres of water and 20 millilitres of sulphuric acid.

Iodide-Sulphate-Chloride Solution (for the determination of blood sugar by Hagedorn and Jensen's method): dissolve 10 grammes of zinc sulphate and 50 grammes of sodium chloride in water to 200 millilitres. When required for use, dissolve 1 gramme of potassium iodide in 40 millilitres of the solution. It is used in conjunction with N/10 sodium hydroxide, 0·45 per cent. w/v zinc sulphate solution, alkaline potassium ferricyanide solution, 1 per cent. w/v solution of soluble starch in saturated sodium chloride solution, and N/200 sodium thiosulphate.

Iodine Solution: 2 per cent. w/v of iodine and 3 per cent. w/v of potassium iodide in water.

Iodine Solution, Gram's: *Synonym.*—Gram's Iodine: 1 gramme of iodine and 2 grammes of potassium iodide in 300 millilitres of water.

Iodine Solution, N/10: a solution of iodine in an aqueous solution of potassium iodide containing in 1000 millilitres, 18·00 grammes of KI and 12·69 grammes of I.

Iodine Water: 1 volume of N/10 iodine solution mixed with 4 volumes of water.

Lactophenol Solution: 20 grammes of phenol dissolved in a mixture of 20 grammes of lactic acid, 40 grammes of glycerin and 20 millilitres of water.

Lactose-Bile-salt-Agar Medium: *Synonym.*—McConkey's Neutral Red Bile Salt Agar: 20 grammes of peptone, 10 grammes of lactose and 5 grammes of sodium taurocholate dissolved in 1000 millilitres of water with the aid of heat, adjusted to pH 7·0, and 20 grammes of shredded agar dissolved in the product with the aid of heat; to the liquid medium add 10 millilitres of 0·5 per cent. w/v solution of neutral red.

Lead Acetate Solution: 10 per cent. w/v of lead acetate in recently boiled water.

Lead Indicator, Alkaline: 1 gramme of lead acetate in about 20 millilitres of hot potassium hydroxide solution and diluted with water to 100 millilitres.

Lead Subacetate Solution: strong solution of lead subacetate diluted, if necessary, with water.

Leucocyte Diluting Solution: 10 millilitres of glacial acetic acid diluted with water to 1000 millilitres and coloured with methyl violet.

Reagents—Continued.

Lithium Phospho-tungstate Solution: *Synonym.*—Uric Acid Reagent (for the determination of uric acid in blood): add 100 grammes of sodium tungstate, $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$, to a boiling mixture of 50 millilitres of phosphoric acid (s.g. about 1.75) and 160 millilitres of water and boil for one hour under a reflux condenser. Dissolve 25 grammes of lithium carbonate in 50 millilitres of phosphoric acid diluted with 200 millilitres of water and boil off the carbon dioxide. Mix the two solutions and add water to 1000 millilitres. It is used in conjunction with a 15 per cent. w/v solution of sodium cyanide in N/10 sodium hydroxide, and standard uric acid solution.

Litmus-Bile-salt Medium: *Synonym.*—McConkey's Medium (Double Strength) (for *B. coli communis*): 80 grammes of peptone triturated with 250 millilitres of water and added to 2000 millilitres of hot water in which has been dissolved 20 grammes of sodium taurocholate; the liquid is boiled for thirty minutes, cooled, and 20 grammes of lactose or dextrose added; the product is sterilised in a Koch steamer, adjusted to pH 7.4, and a sufficient quantity of litmus solution added. (This medium is sometimes prepared with neutral red instead of litmus.)

Litmus Solution: boil 10 grammes of litmus for 1 hour with 40 millilitres of alcohol (90 per cent.) and pour off the clear liquid; repeat the boiling, etc., twice with 30 millilitres of alcohol (90 per cent.). Digest the washed litmus with 100 millilitres of water, and filter. pH range, 5 to 8. Colour change, red with acids to blue with alkalis.

Magenta Solution, Decolourised: 1 gramme of magenta dissolved in 600 millilitres of hot water, cooled, and mixed with 10 grammes of anhydrous sodium sulphite dissolved in 100 millilitres of water, 10 millilitres of hydrochloric acid added, and diluted with water to 1000 millilitres; it should be protected from light.

Magnesium Ammonio-Sulphate Solution: *Synonym.*—Magnesia Mixture: 10 grammes of magnesium sulphate and 20 grammes of ammonium chloride dissolved in 80 millilitres of water, and 42 millilitres of dilute ammonia solution added; the mixture is set aside for a few days in a well-closed container, decanted and filtered.

Magnesium Sulphate Solution: 10 per cent. w/v of magnesium sulphate in water.

Mercuric Ammonium Thiocyanate Solution: 3 per cent. w/v of ammonium thiocyanate and 2.7 per cent. w/v of mercuric chloride in water.

Mercuric Chloride Solution: 5 per cent. w/v of mercuric chloride in water.

Reagents—Continued.

Mercuric Sulphate Solution: 5 grammes of yellow mercuric oxide mixed with 40 millilitres of water, and 20 millilitres of sulphuric acid added while stirring; 40 millilitres of water added and stirred until solution is completed.

Mercury Nitrate Solution: *Synonym.*—Millon's Reagent: recently prepared by dissolving 3 millilitres of mercury in 27 millilitres of fuming nitric acid without the aid of heat, and diluting with an equal volume of water.

Methyl Orange Solution: 0.04 per cent. w/v of methyl orange (sodium dimethylaminoazobenzenesulphonate) in alcohol (20 per cent.). pH range, 2.8 to 4. Colour change, red in moderately acid solutions to yellow in weakly acid and alkaline solutions.

Methyl Red Solution: 0.025 per cent. w/v of methyl red (dimethylaminoazobenzene-*o*-carboxylic acid) dissolved by warming with 0.95 millilitre of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.), and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 4.2 to 6.3. Colour change, red in weakly acid solutions to yellow in very weakly acid and alkaline solutions.

Methylene Blue Solution: *Synonym.*—Loeffler's Solution: 33 millilitres of a saturated alcoholic solution of methylene blue mixed with 100 millilitres of a 1 in 10,000 solution of potassium hydroxide.

Methylene Blue and Borax Solution: *Synonym.*—Sabouraud's Stain: 20 millilitres of 5 per cent. w/v aqueous solution of borax, 30 millilitres of saturated aqueous solution of methylene blue, and 50 millilitres of water.

Methylene Blue and Eosin Solution: *Synonym.*—Jenner's Stain (for staining blood films): 100 millilitres of a 0.5 per cent. w/v solution of methylene blue in dehydrated methyl alcohol mixed, when required for use, with 125 millilitres of a 0.05 per cent. w/v solution of eosin in dehydrated methyl alcohol.

Methylene Blue and Eosin Solution: *Synonym.*—Leishman's Stain (for staining blood films): a solution containing 1 per cent. of methylene blue and 0.5 per cent. of sodium carbonate in sterilised water is maintained at 65° for twelve hours and then allowed to stand for ten days at ordinary temperatures. It is then mixed with an equal volume of 0.1 per cent. w/v aqueous solution of eosin and allowed to stand with occasional stirring for six to twelve hours, when the precipitate is collected, washed, dried, and dissolved in dehydrated methyl alcohol to form a 0.2 per cent. w/v solution.

Methylene Blue and Vesuvine Solution: *Synonym.*—Neisser's Stain: (A) 0.1 gramme of methylene blue in a mixture of 2 millilitres of alcohol (95 per cent.), 5 millilitres of glacial acetic acid and 95 millilitres of water. (B) 0.2 gramme of vesuvine bismarck brown in 100 millilitres of water.

Reagents—Continued.

Nitric Acid Solution, Dilute: 10 per cent. w/w of HNO_3 in water.

Nitric Acid Solution, Strong: nitric acid diluted with an equal volume of water.

Nitric Acid, Fuming: specific gravity at 15.5° , about 1.5.

Nitric Acid PbT. : nitric acid which complies with the following test:—Make 5 grammes alkaline with solution of ammonia PbT. , add 1 millilitre of solution of potassium cyanide PbT. , dilute to 50 millilitres with water and add two drops of solution of sodium sulphide PbT. ; no darkening is produced.

Nutrient Agar Medium: 20 grammes of shredded agar dissolved by the aid of heat in 1000 millilitres of nutrient broth. Sterilise by heating in an autoclave.

Nutrient Broth: 5 grammes of meat extract, 10 grammes of peptone and 5 grammes of sodium chloride boiled with 1000 millilitres of water for thirty minutes. The reaction of the solution is adjusted to pH 7.6, the volume adjusted to 1000 millilitres, and the liquid sterilised by heating in an autoclave.

Nutrient Broth: (for Rideal-Walker test): 20 grammes of peptone rubbed to a cream with water is added slowly to a boiling solution of 20 grammes of meat extract in 750 millilitres of water; 10 grammes of sodium chloride is added and the liquid boiled for thirty minutes, cooled, and water added to one litre. An aliquot portion is titrated at 37° with N/10 sodium hydroxide until neutral to phenolphthalein, and the calculated quantity of N/1 sodium hydroxide is then added very slowly to the remainder to render it neutral to phenolphthalein at 37° . The mixture is heated to the boiling-point and filtered while hot. By the addition of N/1 hydrochloric acid the reaction of the solution is adjusted to pH 7.6, using phenol red as indicator. The broth is sterilised by heating in an autoclave, filtered when cold, distributed into tubes each containing 5 millilitres, and again autoclaved. The final reaction of the broth is between pH 7.3 and pH 7.5.

Nutrient Gelatin Medium: 125 grammes of gelatin dissolved in 100 millilitres of nutrient broth and the reaction of the solution readjusted to pH 7.6. Sterilise by tyndallisation.

Orcinol Solution: *Synonym.* —Bial's Reagent (for the detection of pentoses in urine): 4 grammes of orcinol dissolved in 200 millilitres of alcohol (95 per cent.) and 5 millilitres of 10 per cent. w/v ferric chloride solution added. For use, add 0.5 millilitre of the solution to 5 millilitres of hydrochloric acid.

Osmic Acid Solution: 1 per cent. w/v of osmic acid in water. The solution must be protected from light.

Oxalic Acid Solution, N/1: an aqueous solution of oxalic acid containing in 1000 millilitres 63.02 grammes of $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$.

Reagents—Continued.

Phenolphthalein Solution: 0.2 gramme of phenolphthalein dissolved in 60 millilitres of alcohol (90 per cent.) and water to 100 millilitres. pH range, 8.3 to 10. Colour change, colourless in acid and weakly alkaline solutions to red in more strongly alkaline solutions.

Phenolphthalin Solution: *Synonyms.*—Kastle-Meyer Reagent; Reduced Phenolphthalein Solution (for the detection of blood in urine, fæces, etc.): to a solution of 2 grammes of phenolphthalein and 20 grammes of potassium hydroxide in 100 millilitres of water add 10 grammes of zinc powder and boil until colourless; pour off the clear liquid, add water to 100 millilitres and then add a trace of zinc powder. Filter before use.

Phenol Red Solution: 0.05 gramme of phenol red (phenolsulphonephthalein) warmed with 2.85 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and diluted with alcohol (20 per cent.) to 250 millilitres. pH range, 6.8 to 8.4. Colour change, yellow in neutral and very faintly acid solutions to red in weakly alkaline solutions.

Phenol Violet Solution: 0.15 gramme of thymol blue (thymolsulphonephthalein) and 0.025 gramme of phenolphthalein warmed with 3.25 millilitres of N/10 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved, and alcohol (20 per cent.) added to 250 millilitres. pH range, 8 to 10. Colour change, yellow in acid and weakly alkaline solutions to blue and finally violet as the alkalinity increases.

Phenoldisulphonic Acid: 15 grammes of phenol heated on a water-bath for six hours with 100 millilitres of sulphuric acid and transferred to a stoppered bottle.

Phloroglucinol Solution: 1 per cent. w/v of phloroglucinol in alcohol (90 per cent.).

Phloroglucinol and Vanillin Solution: *Synonym.*—Guenzburg's Solution (for the detection of free hydrochloric acid in the stomach): (A) 10 per cent. w/v of phloroglucinol in dehydrated alcohol. (B) 10 per cent. w/v of vanillin in dehydrated alcohol. For use, mix 2 parts by volume of A with 1 part by volume of B.

Phosphomolybdic Acid Solution: (for the determination of blood sugar by Folin and Wu's method): 35 grammes of molybdic acid and 5 grammes of sodium tungstate, $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$, added to 200 millilitres of 10 per cent. w/v solution of sodium hydroxide diluted with 200 millilitres of water, boiled vigorously for thirty minutes, cooled, diluted to 350 millilitres, mixed with 125 millilitres of phosphoric acid (specific gravity, about 1.75), and water to 500 millilitres. It is used in conjunction with sodium tungstate solution, 2/3 N sulphuric acid, sodio-cupric tartrate solution, and dilutions of a standard 1 per cent. w/v solution of anhydrous dextrose in saturated aqueous benzoic acid solution.

Reagents—Continued.

Platinic Chloride Solution: 5 per cent. w/v of platinic chloride, $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$, in water.

Potassio-Cupric Tartrate Solution: *Synonym.*—Fehling's Solution: **No. 1.** 34.64 grammes of copper sulphate with 0.5 millilitre of sulphuric acid dissolved in sufficient water to produce 500 millilitres. **No. 2.** 176 grammes of sodium potassium tartrate and 77 grammes of sodium hydroxide, dissolved in sufficient water to produce 500 millilitres. Mix equal volumes of solutions No. 1 and No. 2 immediately before use.

Potassio-Mercuric Iodide Solution: *Synonym.*—Mayer's Reagent: 1.355 grammes of mercuric chloride dissolved in 60 millilitres of water, and 5 grammes of potassium iodide dissolved in 20 millilitres of water, mixed and diluted with water to 100 millilitres.

Potassio-Mercuric Iodide Solution, Alkaline: *Synonym.*—Nessler's Reagent: to 3.5 grammes of potassium iodide and 1.25 grammes of mercuric chloride, dissolved in 80 millilitres of water, add a cold saturated solution of mercuric chloride in water, with constant stirring, until a slight red precipitate remains; add 12 grammes of sodium hydroxide, a little more saturated solution of mercuric chloride and water to produce 100 millilitres; allow to stand, and decant the clear liquid.

For use in chemical pathology the reagent is prepared by the following method:—15 grammes of mercuric iodide dissolved in a solution of 11.25 grammes of potassium iodide in 7.5 millilitres of water, filtered, diluted to 300 millilitres and mixed with 700 millilitres of 10 per cent. w/v sodium hydroxide solution.

Potassium Aluminium Sulphate Solution, M/10: an aqueous solution of potash alum containing in 1000 millilitres 47.44 grammes of $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$.

Potassium Bromate Solution, N/10: an aqueous solution of potassium bromate containing in 1000 millilitres 2.784 grammes of KBrO_3 .

Potassium Chromate Solution: 5 per cent. w/v of potassium chromate in water; it gives a red precipitate with silver nitrate in neutral solution.

Potassium Cyanide Solution: 10 per cent. w/v of potassium cyanide in water.

Potassium Dichromate Solution: 7 per cent. w/v of potassium dichromate in water.

Potassium Dichromate Solution, N/10: an aqueous solution of potassium dichromate containing in 1000 millilitres 4.904 grammes of $\text{K}_2\text{Cr}_2\text{O}_7$.

Reagents—Continued.

Potassium Ferricyanide Solution: freshly prepared by washing 1 gramme of potassium ferricyanide, in crystals, with a little water and dissolving in 100 millilitres of water; it gives a blue colour with solutions of ferrous salts.

Potassium Ferricyanide Solution, Alkaline (for the determination of blood sugar by Hagedorn and Jensen's method): 1·65 grammes of potassium ferricyanide and 10·6 grammes of anhydrous sodium carbonate in water to 1000 millilitres. It is used in conjunction with iodide-sulphate-chloride solution, N/10 sodium hydroxide, 1·45 per cent. w/v zinc sulphate solution, 1 per cent. w/v solution of soluble starch in saturated sodium chloride solution, and N/200 sodium thiosulphate.

Potassium Ferricyanide Solution, M/10: an aqueous solution of potassium ferricyanide containing in 1000 millilitres 32·92 grammes of $K_3Fe(CN)_6$.

Potassium Ferrocyanide Solution: 5 per cent. w/v of potassium ferrocyanide in water.

Potassium Hydroxide Solution: approximately 5 per cent. w/v of potassium hydroxide in water.

Potassium Hydroxide Solution, Strong: 50 per cent. w/v of potassium hydroxide in water.

Potassium Hydroxide Solution, N/1: an aqueous solution of potassium hydroxide containing in 1000 millilitres 56·10 grammes of KOH.

Potassium Iodate Solution, M/5: an aqueous solution of potassium iodate containing in 1000 millilitres 42·81 grammes of KIO_3 .

Potassium Iodide Solution: 10 per cent. w/v of potassium iodide in water.

Potassium Iodide and Starch Solution: 10 per cent. w/v of potassium iodide and 5 per cent. v/v of mucilage of starch in water, freshly prepared.

Potassium Permanganate Solution: 1 per cent. w/v of potassium permanganate in water.

Potassium Permanganate Solution, N/10: an aqueous solution of potassium permanganate containing in 1000 millilitres 3·161 grammes of $KMnO_4$.

Pyrogallol Solution, Alkaline: 0·5 gramme of pyrogallol dissolved in 2 millilitres of water, and 12 grammes of potassium hydroxide in 8 millilitres of water, mixed immediately before use.

Reagents—Continued.

Resorcinol Solution, Acid: *Synonym.*—Seliwanoff's Reagent (for the detection of lævulose): 0.1 gramme of resorcinol dissolved in 200 millilitres of a 33 per cent. v/v dilution of hydrochloric acid.

Ruthenium Red Solution: freshly prepared by dissolving 0.008 gramme of ruthenium red (ammoniated ruthenium hydroxy-chloride) in 10 millilitres of a 10 per cent. w/v solution of lead acetate in water.

Salicylsulphonic Acid Solution (for the detection of protein in urine): a saturated solution of salicylsulphonic acid in water.

Scarlet Red Solution: a mixture of 70 millilitres of alcohol (90 per cent.), 10 millilitres of water and 20 millilitres of a 10 per cent. w/v aqueous solution of potassium hydroxide, saturated with scarlet red.

Silver Nitrate Solution: 5 per cent. w/v of silver nitrate in water.

Silver Nitrate Solution, Alcoholic: 4 grammes of silver nitrate in 10 millilitres of water, with sufficient alcohol (95 per cent.) to produce 100 millilitres.

Silver Nitrate Solution, Ammoniacal: dissolve 2.5 grammes of silver nitrate in about 80 millilitres of water, add nearly sufficient solution of ammonia to dissolve the precipitate first formed, allow to stand, decant, and add sufficient water to produce 100 millilitres.

Silver Nitrate Solution, N/10: an aqueous solution of silver nitrate containing in 1000 millilitres 16.99 grammes of AgNO_3 .

Soap Solution, Standard: 10 grammes of hard soap dissolved in alcohol (35 per cent.) to 1000 millilitres, the resulting solution being adjusted by the addition of alcohol (35 per cent.) until 13 millilitres is required for the production of a lather permanent for five minutes when shaken with 100 millilitres of water containing in solution neutral calcium chloride equivalent to 0.012 gramme of CaCO_3 .

Sodio-Bismuth Tartrate Solution, Alkaline: *Synonym* -- Nylander's Reagent (for the detection of reducing substances in urine): 40 grammes of sodium potassium tartrate and 20 grammes of bismuth subnitrate dissolved in 1000 millilitres of 8 per cent. w/v aqueous solution of sodium hydroxide.

Sodio-Cupric Citrate Solution: *Synonym.*—Benedict's Solution -- Qualitative: 100 grammes of anhydrous sodium carbonate (or 270 grammes of sodium carbonate) dissolved with the aid of gentle heat in 600 millilitres of water, 173 grammes of sodium citrate added, the solution cooled, a cold solution of 17.3 grammes of copper sulphate in 100 millilitres of water added slowly with constant stirring, and the liquid diluted to 1000 millilitres.

Reagents—Continued.

Sodio-Cupric Citro-thiocyanate Solution: *Synonym.*—Benedict's Solution—Quantitative: 18 grammes of copper sulphate dissolved in 100 millilitres of water and poured slowly, with constant stirring, into a cold solution of 200 grammes of sodium carbonate, 200 grammes of sodium citrate and 125 grammes of potassium thiocyanate in water to 800 millilitres; 5 millilitres of 5 per cent. w/v solution of potassium ferrocyanide added and water to 1000 millilitres.

Sodio-Cupric Tartrate Solution: *Synonym.*—Alkaline Copper Tartrate Solution (for the determination of blood sugar by Folin and Wu's method): to 40 grammes of anhydrous sodium carbonate dissolved in 400 millilitres of water add 7.5 grammes of tartaric acid and, when solution is complete, 4.5 grammes of copper sulphate and water to 1000 millilitres. It is used in conjunction with sodium tungstate solution, 2/3 N sulphuric acid, phosphomolybdic acid solution, and dilutions of a standard 1 per cent. w/v solution of anhydrous dextrose in saturated aqueous bismucic acid solution.

Sodium Arsenite Solution, N/100: an aqueous solution of sodium arsenite containing in 1000 millilitres arsenic trioxide equivalent to 0.6495 gramme of NaAsO_2 .

Sodium Carbonate Solution: 10 per cent. w/v of sodium carbonate in water.

Sodium Carbonate Solution, N/1: an aqueous solution of sodium carbonate containing in 1000 millilitres 53.00 grammes of Na_2CO_3 .

Sodium Chloride Solution: *Synonym.*—Brine: a saturated solution of sodium chloride in water.

Sodium Hydroxide Solution: 20 per cent. w/v of sodium hydroxide in water.

Sodium Hydroxide Solution, Dilute: 5 per cent. w/v of sodium hydroxide in water.

Sodium Hydroxide Solution, N/1: an aqueous solution of sodium hydroxide containing in 1000 millilitres 40.00 grammes of NaOH .

Sodium Hypobromite Solution: 10 per cent. v/v of bromine in 40 per cent. w/v aqueous solution of sodium hydroxide. It should be freshly prepared.

Sodium Nitroprusside Solution: a freshly prepared 1 per cent. w/v solution of sodium nitroprusside, $\text{Na}_2\text{Fe}(\text{CN})_5\text{NO}\cdot 2\text{H}_2\text{O}$, in water.

Sodium Nitroprusside Solution: *Synonym.*—Rothera's Solution (for the detection of acetone and acetoacetic acid in urine): a freshly prepared 5 per cent. w/v solution of sodium nitroprusside in water.

Reagents—Continued.

Sodium Nitroprusside and Ammonium Sulphate (for Rothera's test for acetone and acetoacetic acid in urine): 100 grammes of powdered ammonium sulphate mixed with 1 gramme of powdered sodium nitroprusside.

Sodium Phosphate Solution: 10 per cent. w/v of sodium phosphate in water.

Sodium Sulphate Solution: 10 per cent. w/v of sodium sulphate in water.

Sodium Sulphate Solution, Acid (for the determination of blood sugar by MacLean's method): 15 grammes of sodium sulphate dissolved in water to 100 millilitres and mixed, when required for use, with 0.1 millilitre of glacial acetic acid.

Sodium Sulphide Solution: 10 per cent. w/v of sodium sulphide in water.

Sodium Thiosulphate Solution, N/10: an aqueous solution of sodium thiosulphate containing in 1000 millilitres 24.82 grammes of $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$.

Sodium Tungstate Solution (for precipitating proteins): 10 per cent. w/v of sodium tungstate, $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$, in water. It is used in conjunction with $2/3$ N sulphuric acid.

Sodium Tungstate with Sodium Acetate Solution: *Synonym.*—Braemer's Reagent: 1 gramme of sodium tungstate and 2 grammes of sodium acetate in 10 millilitres of water.

Stannous Chloride Solution: add 20 grammes of tin to a mixture of 60 millilitres of hydrochloric acid and 20 millilitres of water, heat gently until hydrogen ceases to be evolved and dilute with water to 100 millilitres, leaving any undissolved tin in the solution.

Starch Mucilage: recently prepared by triturating 0.5 gramme of starch, or 2 grammes of soluble starch, with 5 millilitres of water, and adding to sufficient water to produce 100 millilitres, boiling and cooling.

Sudan III Solution: 0.01 gramme of Sudan III in a mixture of 5 millilitres of alcohol (90 per cent.) and 5 millilitres of glycerin.

Sulphomolybdic Acid Solution: 1 per cent. w/v of ammonium molybdate in sulphuric acid.

Sulphovanadic Acid Solution: *Synonym.*—Mandelin's Reagent: freshly prepared by triturating 1 gramme of ammonium vanadate with 100 millilitres of sulphuric acid; the deposit is allowed to subside, and the clear liquid used.

Sulphuric Acid Solution, Dilute: approximately 10 per cent. w/w of H_2SO_4 in water.

Sulphuric Acid Solution, Strong: 2 volumes of sulphuric acid mixed with 1 volume of water.

Reagents—Continued.

Sulphuric Acid Solution, N/1: an aqueous dilution of sulphuric acid containing in 1000 millilitres 49.04 grammes of H_2SO_4 .

Sulphurous Acid Solution: 6.4 per cent. w/w of sulphurous acid in water (approximately 5 per cent. w/w of SO_2).

Tannic Acid Solution: 10 per cent. w/v of tannic acid in water.

Tartaric Acid Solution: 12.5 grammes of tartaric acid dissolved in 60 millilitres of water, with 25 millilitres of alcohol (90 per cent.) and water to 100 millilitres.

Thymol Blue Solution: 0.1 gramme of thymol blue (thymolsulphonephthalein) warmed with 4.3 millilitres of N/20 sodium hydroxide and 5 millilitres of alcohol (90 per cent.) until dissolved and diluted with alcohol (20 per cent.) to produce 250 millilitres. pH range, 1.2 to 2.8, and 8.0 to 9.6. Colour change, red in strongly acid solutions, yellow in weakly acid and weakly alkaline solutions to blue in more strongly alkaline solution.

Titanous Chloride Solution: approximately 15 per cent. w/v of titanous chloride, TiCl_3 , in water.

Titanous Chloride Solution, N/10: titanous chloride solution diluted with hydrochloric acid and water to contain 15.427 grammes of TiCl_3 in 1000 millilitres. To 103 millilitres of titanous chloride solution and 103 millilitres of hydrochloric acid, add recently boiled and cooled water to 1000 millilitres. Standardise immediately before use by titration in an atmosphere of carbon dioxide against N/10 ferric ammonium sulphate, using ammonium thiocyanate as indicator. It should be stored in completely filled bottles or in an atmosphere of hydrogen or carbon dioxide.

Trichloroacetic Acid and Ferric Chloride Solution: *Synonym.*—Fouchet's Reagent (for the detection of bilirubin in serum or plasma): 25 grammes of trichloroacetic acid dissolved in 100 millilitres of water and mixed with 10 millilitres of a 10 per cent. w/v solution of ferric chloride, FeCl_3 .

Trinitrophenol Solution: 0.66 per cent. w/v of trinitrophenol in water.

Trinitrophenol and Citric Acid Solution: *Synonym.*—Aufrecht's Reagent (for the determination of protein in urine): 15 grammes of trinitrophenol and 30 grammes of citric acid dissolved in water to 1000 millilitres.

Trinitrophenol and Citric Acid Solution: *Synonym.*—Esbach's Solution (for the determination of protein in urine): 10 grammes of trinitrophenol and 20 grammes of citric acid in water to 1000 millilitres.

Trypsin Broth: 1 pound of minced lean beef is added to 100 millilitres of water and 20 millilitres of N/1 sodium hydroxide solution, allowed to stand over night, and then maintained at 75° to 80° for five minutes. Cool to 37° , add 10 millilitres of 1 per cent. trypsin and maintain at 37° for three hours. Allow to stand over night, siphon off the clear liquid, filter, adjust to pH 7.2 and autoclave.

Reagents—Continued.

Turmeric Tincture: macerate 10 grammes of bruised turmeric in 60 millilitres of alcohol (90 per cent.) for seven days, and filter.

Uric Acid Solution, Concentrated, Standard: dissolve 0.1 gramme of uric acid in a warm solution of 0.05 gramme of lithium carbonate in 20 millilitres of water, add 5 millilitres of solution of formaldehyde and 1 millilitre of acetic acid (50 per cent.) and dilute to 100 millilitres.

Uric Acid Solution, Standard (for the determination of uric acid in blood): 1 millilitre of concentrated standard uric acid solution diluted with water containing 10 millilitres of $2/3$ N sulphuric acid and 1 millilitre of solution of formaldehyde to 250 millilitres.

Water: the distilled water of the British Pharmacopœia.

Water, Ammonia-free: water giving no colour when 2 millilitres of alkaline potassio-mercuric iodide solution is added to 50 millilitres.

Zinc Solution, Ammoniacal: 7.70 grammes of zinc dissolved in about 75 millilitres of dilute hydrochloric acid, an excess of ammonia solution added, and diluted to 1000 millilitres with water.

APPENDIX VII

Quantitative Test for Arsenic

The apparatus, reagents and solutions, and the general method of testing to be used for the quantitative test for arsenic in the substances of the British Pharmaceutical Codex are those of the British Pharmacopœia, 1932. The solution to be examined is prepared by one of the methods described in the British Pharmacopœia or by a method described in the table below, and is tested in a manner corresponding to the quantitative test for arsenic in the substances of the British Pharmacopœia.

The following table gives the method, or the substance in the British Pharmacopœia to which reference must be made for the method, of preparing the solution to be tested, together with the quantity to be taken when the test is used as a limit test in which the stain is not deeper than the 1 millilitre standard stain corresponding to the arsenic limit stated in the monograph.

Substance	Method or reference substance for preparing the solution to be examined	Grammes of substance employed	Limit of arsenic, parts per million
Acidum Glycero-phosphoricum ..	Acidum Aceticum ..	4	2·5
Acidum Hydriodicum Dilutum ..	Add 50 millilitres of hot water, 0·5 millilitre of solution of bromine AsT., and 10 millilitres of hydrochloric acid AsT.; allow to stand for five minutes, and remove the excess of bromine with a few drops of solution of stannous chloride AsT.	2	5
Acidum Sulphuricum	Mix in the cold with 0·5 gramme of potassium chlorate AsT., and 11 millilitres of hydrochloric acid AsT., warm to expel excess of chlorine, then add 50 millilitres of hot water and a few drops of solution of stannous chloride AsT.	2	5

Quantitative Test for Arsenic—Continued.

Substance	Method or reference substance for preparing the solution to be examined	Grammes of substance employed	Limit of arsenic, parts per million
Aluminii Hydroxidum	Acidum Citricum ..	0.5	20
Aluminii Sulphas ..	Acidum Citricum ..	2	5
Ammonii Acetas ..	Acidum Citricum ..	2	5
Ammonii Benzoas ..	Acidum Acetylsalicylicum	5	2
Ammonii Bromidum	Calcii Lactas	2	5
Ammonii Citras ..	Acidum Citricum ..	5	2
Ammonii Hippuras	Acidum Acetylsalicylicum	2	5
Ammonii Iodidum	Calcii Lactas	2	5
Ammonii Phosphas	Potassii Acetas	2	5
Ammonii Salicylas	Acidum Acetylsalicylicum	5	2
Ammonii Sulphas ..	Potassii Acetas	1	10
Ammonii Tartras ..	Acidum Citricum ..	2	5
Antimonii Oxidum	Antimonii et Potassii Tartras	0.01	1000
Antimonium Sulphuratum	Dissolve by boiling in a small flask with 0.2 gramme of calcium hydroxide AsT. and 5 millilitres of water, then add 2 millilitres of solution of bromine AsT. and again gently boil, then add 17 millilitres of hydrochloric acid AsT. and 5 millilitres of water and boil until most of the bromine is volatilised, the last traces being removed by adding a slight excess of solution of stannous chloride AsT.; connect to a condenser and distil 20 millilitres, then wash the condenser and flask, return the distillate to the flask, adding	0.01	1000

Quantitative Test for Arsenic—Continued.

Substance	Method or reference substance for preparing the solution to be examined	Grammes of substance employed	Limit of arsenic, parts per million
	1 drop of solution of stannous chloride AsT., and redistil 16 millilitres, then add to the distillate 45 millilitres of hot water and a few drops of solution of stannous chloride AsT.		
Azorubrum ..	Methylthioninæ Chloridum	0.3	30
Bismuthi Citras ..	Bismuthi Salicylas ..	5	2
Bismuthi et Ammonii Citras ..	Bismuthi Salicylas ..	5	2
Bismuthi et Sodii Tartras ..	Bismuthi Salicylas ..	5	2
Bismuthi Naphtholas	Bismuthi Salicylas ..	5	2
Bismuthi Oxidum ..	Bismuthi Carbonas ..	5	2
Bismuthi Subgallas	Bismuthi Salicylas ..	5	2

APPENDIX VIII

Quantitative Test for Lead

The apparatus, reagents and solutions, and the general method of testing to be used for the quantitative test for lead in the substances of the British Pharmaceutical Codex are those of the British Pharmacopœia. Any special tests and directions needed are indicated below and are to be applied in a manner corresponding to the quantitative test for lead in the substances of the British Pharmacopœia.

The following table gives the quantities to be used in the primary and auxiliary solutions, together with the quantities of acetic acid PbT. required and the quantities of the dilute solution of lead PbT. corresponding to the lead limits stated in the monographs.

Substance	Primary Solution		Auxiliary Solution		Milli- litres of dilute solution of lead PbT. em- ployed	Limit of lead, parts per million
	Grammes of substance employed	Milli- litres of acetic acid PbT.	Grammes of sub- stance em- ployed	Milli- litres of acetic acid PbT.

Notes

a. Solution effected by the addition of solution of ammonia PbT.

b. Primary solution prepared by dissolving 1 gramme in 10 millilitres of dilute hydrochloric acid PbT. and adding 25 millilitres of solution of ammonium citrate PbT. Auxiliary solution, 25 millilitres of solution of ammonium citrate PbT.

c. Primary solution prepared as follows:—Heat 1 gramme with 5 millilitres of water and 5 millilitres of nitric acid PbT. in a round-bottomed flask until the first reaction has subsided, cool, add 2.5 millilitres of sulphuric acid PbT. and heat until the mixture begins to darken, then add drop by drop, while still heating, 3 millilitres, or a sufficient quantity, of nitric acid PbT. and continue the heating until white fumes are given off and the liquid is almost colourless. Cool, dilute with 5 millilitres of water and evaporate until white fumes are again given off. Cool, dilute with 100 millilitres of water and dissolve 2 grammes of citric acid PbT. in the liquid, then make alkaline with solution of ammonia PbT. and add 1 millilitre of solution of potassium cyanide PbT. Transfer to a separator, add 10 millilitres of solution of diphenylthiocarbazone PbT. and shake vigorously. Allow the liquids to separate and run off the lower layer. Repeat the extraction

Quantitative Test for Lead—Continued.

with two further quantities of 5 millilitres of solution of diphenylthiocarbazone PbT. Wash each solution with the same 10 millilitres of water contained in a second separator. Evaporate the mixed solutions to dryness, add 0.5 millilitre of sulphuric acid PbT. to the residue and heat until white fumes are given off, then add, drop by drop, 0.5 millilitre of nitric acid PbT. and continue the heating until white fumes are again given off and the liquid is almost colourless. Cool, dilute with 35 millilitres of water, add 5 millilitres of acetic acid PbT., 10 millilitres of solution of ammonia PbT. and 1 millilitre of solution of potassium cyanide PbT.

Auxiliary solution prepared by mixing 5 millilitres of acetic acid PbT. with 30 millilitres of water, 10 millilitres of solution of ammonia PbT. and 1 millilitre of solution of potassium cyanide PbT.

d. Primary solution prepared by dissolving 3 grammes in 18 millilitres of 33 per cent. w/v potassium hydroxide solution PbT. Auxiliary solution prepared by dissolving 1 gramme in 6 millilitres of the same solution.

e. Primary solution prepared by dissolving 0.033 gramme in a boiling solution of 1 gramme of potassium acid tartrate in 30 millilitres of water and adding 5 millilitres of solution of sodium hydroxide PbT. Auxiliary solution, 1 gramme of potassium acid tartrate in 30 millilitres of water with 5 millilitres of solution of sodium hydroxide PbT.

f. Filter off any caffeine that may be precipitated on the addition of solution of ammonia PbT.

g. Primary solution prepared as follows:—Dissolve 2 grammes in 20 millilitres of hydrochloric acid PbT., and add 0.5 millilitre of nitric acid PbT. Boil for one minute, cool and pour into a separator. Extract the iron with 20, 20 and 20 millilitres of ether. If the acid liquid is still more than faintly yellow, make an additional extraction with 20 millilitres of ether. Reject the ether extracts. Pour the acid solution into a narrow-necked flask, rinsing the separator with about 5 millilitres of water. Heat gently to volatilise the dissolved ether, make alkaline with solution of ammonia PbT., add 1 millilitre of solution of potassium cyanide PbT. and adjust the volume to 50 millilitres with water.

h. Primary solution prepared by dissolving 1 gramme in 20 millilitres of water, adding 2 millilitres of acetic acid PbT., 2 grammes of ammonium chloride PbT. and 1 millilitre of potassium cyanide solution PbT., making strongly alkaline with dilute ammonia PbT., adjusting the volume to 35 millilitres, and adding 15 millilitres of water containing one drop of sodium sulphide solution PbT. Auxiliary solution prepared in the same way, omitting the manganese salt.

APPENDIX IX

The Determination of Foreign Organic Matter

The following process is applicable to the determination of foreign organic matter in powdered vegetable drugs when the foreign organic matter possesses some definite microscopical character which differs from the characters of the drug itself, and is at the same time sufficiently well marked to be easily recognised. Amongst such substances may be distinguished two distinct types of material which require slightly different treatment, although the basic principle is the same in both instances.

1. The first class of substances includes those which consist wholly of, or contain, characteristic minute particles of well-defined shape and size, such as starch granules and pollen grains.

The method is as follows:—

First reduce the material to a No. 85 powder and determine the loss in weight of the powder when dried at 100°. Mix thoroughly 0.1 gramme of the air-dry powder with 0.05 gramme of lycopodium spores on a glass plate with the aid of a small flexible spatula, holding a second glass plate to screen the powder from being blown away by breathing. Rub the mixture into a smooth paste with a few drops of suspending fluid, such as a mixture of two volumes of glycerin, one volume of mucilage of tragacanth and two volumes of water, or, in the case of oily powders, olive oil or castor oil. Transfer the suspension to a small corked tube, rub the residue on the plate with a further quantity of the suspending fluid, transfer it to the tube and repeat the process until none of the powder remains on the plate. Add sufficient of the suspending fluid to produce a liquid of which one drop, when mounted and examined with the 4 millimetre objective, shows from 10 to 20 lycopodium spores in each field; in most cases this result will be obtained when the total volume is about 10 millilitres. Shake the corked tube gently for about three minutes to ensure uniform distribution of the particles without the introduction of air-bubbles. By means of a dry glass tube of small bore (about 2 to 3 millimetres), transfer one drop of the suspension to a microscope slide; stir the drop with a thin glass rod or a needle, spread it over an area a little less than that of the cover glass to be used, then apply the cover glass gently and quickly. Leave the slide on a level place so as to allow the particles to settle evenly. Count the characteristic particles of the adulterant and the spores present in the same 25 fields selected according to the scheme illustrated in the figure. Make another count in a second mount. Prepare another suspension and repeat the whole operation. From the mean of the four results, which should not differ by more than 10 per cent. for the two suspensions, calculate the number of the particles present in one gramme of the powder under examination, dried at 100°. The number of the characteristic particles per gramme of the pure adulterant, calculated on the pure adulterant dried at 100°, is then either determined experimentally or found by

The Determination of Foreign Organic Matter—Continued.

FIG. 1.—Diagram showing the position of the 25 fields selected for counting the spores and tracing the particles: *cov.* edge of cover-glass; *co. sq.* counting square. The numbers indicate the distance in millimetres of the position of the field from the centre of the cover-glass.

reference to the literature. The percentage of adulterant is calculated according to the following formula:—

$$\text{Percentage of adulterant} = \frac{n \times w \times 94000 \times 100}{s \times m \times p}$$

where:—

n = number of characteristic particles of adulterant in 25 fields.

s = number of spores in the same 25 fields.

w = weight in milligrams of the lycopodium taken.

m = weight in grammes of the sample, calculated on the sample dried at 100°.

94000 = number of spores per milligram of lycopodium.

p = number of characteristic particles per gramme of the pure adulterant, calculated on the pure adulterant dried at 100°.

NOTE.—When the moisture in the air-dry powder is evenly distributed, the percentage of air-dry adulterant in the air-dry powder is identical with that calculated by the formula given above.

The Determination of Foreign Organic Matter—Continued.

2. The second class of substances includes those which possess:—

(a) A tissue composed of easily recognisable cells which form a characteristic layer that is only one cell in thickness, e.g. epidermal tissues and such tissues as the sclerenchymatous layer of linseed.

(b) Characteristic cells which occur singly or in single files, e.g. the bast fibres of cinnamon and of cinchona.

For powders of this type the general method of procedure is similar to that described above, but it is usually necessary to use, in addition to the suspending medium, a clearing or staining reagent and, instead of counting the particles, to determine their area.

For clearing a powder having a characteristic epidermis, the powder and lycopodium are placed in a tube with 3 to 3.5 millilitres of solution of chloral hydrate, and the tube is heated by immersion in boiling water, with occasional shaking, for about five minutes or until the particles are almost colourless. Cool, and add the required amount of suspending fluid, consisting of two volumes of glycerin, one volume of mucilage of tragacanth and two volumes of water.

For staining lignified particles, rub the mixture of lycopodium and powder into a paste with 1 millilitre of solution of phloroglucinol, allow it to evaporate almost to dryness and add 1 millilitre of strong hydrochloric acid, mix thoroughly, and incorporate a few drops of glycerin, transfer to the corked tube and add the suspending fluid, to which, if necessary, a clearing agent such as 1 millilitre of solution of chloral hydrate is added. Make a mount as described above and, by means of a camera lucida, trace the outline of the characteristic particles at a definite magnification, such as 400 diameters, and count the spores present in the same 25 fields. Determine the total area of the tracings by cutting the paper along the outlines of the tracings, weighing the pieces so cut out, and multiplying by the area of one gramme of the paper used.

In a similar way determine the total area of characteristic particles present in 1 gramme of the pure adulterant, calculated on the pure adulterant dried at 100°, or a standard figure may be obtained from the literature. Calculate the percentage of adulterant from the following formula:—

$$\text{Percentage of adulterant} = \frac{f \times w \times 94000 \times 100}{400^2 \times s \times m \times a}$$

where:—

f = area of characteristic particles in 25 fields at a magnification of 400 diameters.

s = number of spores in 25 fields.

w = weight in milligrams of the lycopodium taken.

m = weight in grammes of the sample, calculated on the sample dried at 100°.

94000 = number of spores per milligram of lycopodium.

a = area of characteristic particles per gramme of the pure adulterant, calculated on the pure adulterant dried at 100°.

The Determination of Foreign Organic Matter—Continued.

NOTE.—When foreign organic matter is present in small proportion, such as 2 per cent., a larger area of the mounts must be used for counting or tracing the particles. In such cases, an area of about 40 square millimetres is sufficient and is obtained by counting nine strips across the counting square and spaced at 1.5 millimetres apart, each strip having a width equal to the diameter of the field of view of the microscope. For other proportions of adulterant, the area selected would lie between that of 25 fields and 40 square millimetres, and can easily be adjusted by the worker so as to give concordant results.

APPENDIX X

Hydrogen Ion Concentration

Substances in solution differ widely in the amount ionised at similar dilutions; thus, the hydrogen chloride in N/10 hydrochloric acid is almost completely dissociated into hydrogen and chlorine ions, whereas acetic acid in similar concentration is only slightly dissociated. Hence, although both these solutions contain the same amount of hydrogen replaceable by metals, they differ largely in active acidity; hydrochloric acid is said to be a "strong" acid, and acetic acid a "weak" acid. Ions carry electrical charges; the hydrogen ion carries unit positive charge and the chlorine ion carries unit negative charge. Hence solutions of strongly ionised substances will offer little resistance to the passage of an electric current, and the smaller the degree of ionisation the greater will be the resistance of the solution. Owing to this relationship between the degree of ionisation and electrical resistance, the percentage of a substance ionised in solution can be obtained by measuring the resistance of the solution.

By the application of this principle, water is found to be little ionised and the concentration of hydrogen ion works out to be approximately 0.0000001 gramme per litre, or in terms of normality, N/10,000,000.

From the above relationship it is obvious that the concentration of hydroxyl ion must be exactly equivalent to that of the hydrogen ion, and pure water must be exactly neutral. The equilibrium expressed in the above equation is governed by the law of mass action and the condition at equilibrium is given by the following formula, where *K* is the dissociation constant for water:—

$$\frac{[\text{H}^+][\text{OH}']}{[\text{H}_2\text{O}]} = K.$$

In all solutions in which water is the solvent, this equilibrium between un-ionised water and its ions must exist, and such solutions are exactly neutral when the concentration of hydrogen ion is 0.0000001 gramme per litre, acid in reaction when the concentration of hydrogen ion is greater, and alkaline when less than this figure. No reference need be made to the concentration of hydroxyl ion, since it automatically adjusts itself in order to preserve the relationship expressed above. Thus, the term hydrogen ion concentration can be used as a quantitative expression to denote both acidity and alkalinity, and offers the advantage of making it possible to avoid the use of indefinite phrases, such as "strongly acid" and "faintly acid." The disadvantage lies in the awkwardness of the numbers concerned; to say that the hydrogen ion concentration is 0.0000001 gramme per litre is too cumbrous for general adoption, but the common logarithm of this number is — 7.0. Thus

Hydrogen Ion Concentration—Continued.

the term pH is defined as "the common logarithm of the *reciprocal* of the concentration of hydrogen ion expressed in grammes per litre."

That is, $pH = \log. \frac{1}{[H^+]}$. On applying this formula to the above example, $pH = \log. \frac{1}{[H^+]} = \log. \frac{1}{0.0000001} = \log. 10,000,000 = 7.0$.

Hence $pH 7$ is the quantitative expression for absolute neutrality. If the hydrogen ion concentrations of 0.000001 and 0.00000001 gramme per litre be similarly converted into pH , the former becomes $pH 6$ and expresses a hydrogen ion concentration greater than $pH 7$, and the latter becomes $pH 8$ and expresses a concentration less than $pH 7$. Values less than $pH 7$ therefore indicate increasing acidity, and those greater than $pH 7$ indicate increasing alkalinity or decreasing acidity. The limiting values are from about $pH - 0.3$, occurring in $6N$ hydrochloric acid, to about $pH 14.5$, representing $7N$ potassium hydroxide.

Owing to the use of this logarithmic method of expression, a change of one unit in the pH represents a ten-fold change in the hydrogen ion concentration; reference to the diagram on page 1599 shows that $pH 1$ represents a hydrogen ion concentration of 0.1 gramme per litre, $pH 2$ represents 0.01 gramme per litre, $pH 3$, 0.001 gramme per litre, and so on. Intermediate values are expressed as decimals of a pH unit, and thus 0.1 of a unit represents approximately a 20.5 per cent. alteration in the hydrogen ion concentration. Also, the difference between $pH 7$ and $pH 6$ is equivalent to 0.0000009 gramme of hydrogen ion per litre (or to 0.009 millilitre of $N/10$ hydrochloric acid); the difference between $pH 2$ and $pH 1$ is equivalent to 0.09 gramme of hydrogen ion per litre (or to 900 millilitres of $N/10$ hydrochloric acid). Hence, a difference of one unit of pH has a greatly different meaning in terms of acidity according to the distance from the neutral point.

Colorimetric Determination of pH Values

Indicators are compounds which exist in two forms, the pseudo form being incapable of ionisation and the inogenic form being capable of complete dissociation, the ions produced being coloured differently from the un-ionised form. This change is brought about by a variation in the pH of the solution. Different indicators change colour over different ranges of pH , and for each indicator a range of pH can be given which expresses the limiting values at which no dissociation and complete dissociation respectively occur. At each of these limiting pH values the full depth of each of the colours is observed, whilst at intermediate values the whole of the intermediate shades are traversed. Thus, methyl orange exhibits a full red colour in solution of $pH 2.8$ and under, a full yellow colour at $pH 4$ and over, but between $pH 2.8$ and $pH 4$ intermediate shades of orange are observed. It is important to realise that the further the range of the indicator is from $pH 7$ the greater the

Hydrogen Ion Concentration—Continued.

amount of hydrogen ion this range represents. Thus, 20 millilitres of solution just yellow to methyl red requires the equivalent of 0.01 millilitre of N/10 hydrochloric acid to turn red, whereas 20 millilitres of solution just yellow to thymol blue requires the equivalent of 12 millilitres of N/10 hydrochloric acid to turn red. Hence, only those indicators with the same range of *pH* are interchangeable.

A series of indicators of varying ranges can be used for the determination of *pH* values, but, to secure accuracy, solutions of standard *pH* must be used for comparison. Methyl red in a solution of *pH* 4.2 is red, in a solution of *pH* 6.3 is yellow, and intermediately gives different shades of orange. If solutions were made of *pH* 4.4, *pH* 4.6, *pH* 4.8, *pH* 5.0, *pH* 5.2, *pH* 5.4, *pH* 5.6, *pH* 5.8, *pH* 6.0, and *pH* 6.2, all containing the same quantity of methyl red, they could be used to match the tint of an unknown solution which contained the same quantity of the same indicator. The *pH* of dilute solutions of strong acids and strong bases is very sensitive to the smallest trace of impurity such as carbon dioxide, dust from the air, or alkali from the vessels. Hence, for solutions of standard *pH*, so-called "Buffer Solutions" are used, which show very little change in *pH* on dilution or on the addition of small quantities of strong acids or strong bases; in other words, they are fairly stable with respect to *pH*, and the carbon dioxide always present in water does not affect them. Such buffer solutions usually consist of solutions of a salt which is hydrolysed in water, such as the salt of a strong base and a weak acid, with one of the products of hydrolysis. The conditions obtaining in a solution of sodium acetate and acetic acid are represented by the following equations:—

On the addition of a little hydrochloric acid to such a system, part of the hydrogen ions would be utilised in combining with the abundance of acetate ions to form un-ionised acetic acid; addition of potassium hydroxide would result in the formation of un-ionised water through combination of the hydroxyl ions with hydrogen ions. In both cases the active ions are to a large extent removed from the sphere of the reaction by these ionic reactions, and hence the change in the *pH* of the solution is much less than when the same amount of hydrochloric acid or potassium hydroxide is added to a solution not buffered.

The colorimetric determination of the *pH* of a solution consists in comparing the colour with that of suitable buffer solutions after the addition of the same quantity of an indicator. If the test solution is itself slightly coloured, a compensation can be made by viewing the buffer solutions through a simple solution of the substance under examination of the same concentration as that used in the test solution.

		Examples of indicators	pH value	Number of gramme-ions per litre	Difference in gramme-ion concentration	Millilitres of N/10 solution equivalent to difference in ion concentration
ALKALINITY			14	OH' ion 1		
					0.9	9000
			13	OH' ion 0.1	0.09	900
					0.009	90
			12	OH' ion 0.01	0.009	90
					0.0009	9
			11	OH' ion 0.001	0.0009	9
					0.00009	0.9
			10	OH' ion 0.0001	0.00009	0.09
					0.000009	0.009
ACIDITY		Phenolphthalein red colourless red	9	OH' ion 0.00001	0.000009	0.009
		Phenol Red red yellow	8	OH' ion 0.000001	0.0000009	0.009
			7	OH' ion 0.0000001		
				H' ion 0.0000001	0.0000009	0.009
			6	H' ion 0.000001	0.0000009	0.009
		Methyl Red yellow red	5	H' ion 0.00001	0.000009	0.9
			4	H' ion 0.0001	0.00009	9
		Methyl Orange yellow red	3	H' ion 0.001	0.009	90

			1	H' ion 0.1	0.9	9000
			0	H' ion 1		

Hydrogen Ion Concentration—Continued.

The method of procedure for this determination and the quantities of the different reagents required for the preparation of solutions of standard pH are included in an appendix to the British Pharmacopœia.

When a higher degree of accuracy in the determination of pH values is required, an electrical method is used. The method is unaffected by the colour of the liquid, but the apparatus required is somewhat complicated. When an element is placed in a solution of its ions, there is a tendency for the atoms to pass into solution in the form of ions, and this is balanced by the tendency of the ions to pass out of solution. The latter tendency is called the solution pressure, or osmotic pressure of the ions. The difference between the two opposing forces makes itself manifest in the form of electro-motive force. Hydrogen at a pressure of one atmosphere in a normal solution of hydrogen ion develops an E.M.F. of -0.27 volt, and the corresponding value for the calomel electrode is -0.56 volt. Hence the primary cell, formed by the combination of the hydrogen electrode and the calomel electrode, develops a voltage equal to the algebraic difference between them: $-0.27 - (-0.56) = +0.29$ volt when the hydrogen ion concentration is normal or, in other words, at pH 0. A ten-fold change in the osmotic pressure of the solution is equivalent to 0.058 volt when the ion is univalent, but this is equal to a change of 1 in the pH of the solution, and E.M.F. $= 0.29 + 0.058 \times pH$; or,

$$pH = \frac{\text{E.M.F.} - 0.29}{0.058}.$$

Hence, the E.M.F. is directly proportional to the pH and not to the hydrogen ion concentration of the solution. The electrometric method depends, therefore, upon the measurement of the potential difference between the hydrogen electrode, immersed in the test solution, and a standard calomel electrode.

APPENDIX XI

Colloidal Solutions

A very large number of substances can be dispersed, by suitable means, in liquids in which they are generally considered to be insoluble, so that the products resemble true solutions in appearance, but differ in many other properties. These solutions have low osmotic pressures, and when they are dialysed, the dispersed substance does not pass through the membrane. In this respect they resemble solutions of those substances, such as glue and gelatin, to which the name colloid was originally restricted, and they are, therefore, known as colloidal solutions or "sols." In the majority of sols of pharmaceutical interest the liquid medium is water, the principal exceptions being found in the collodions and certain emulsions. The following description applies principally to aqueous sols.

The fact that a substance in colloidal solution does not pass through a parchment membrane is due to the larger size of the particles. In true solutions the particles are of molecular dimensions, the size being of the order of $0.1 \mu\mu$ (10^{-7} millimetre). The particles of dispersed substance in a colloidal solution consist of aggregates of a large number of molecules and, in general, colloidal phenomena are shown by liquids in which the dispersed particles vary in size between about $1 \mu\mu$ and $100 \mu\mu$. The properties of liquids containing smaller particles approximate more closely to those of true solutions, while liquids containing larger particles resemble ordinary suspensions; there is, however, no clear distinction between the three classes, and solutions of substances of high molecular weight and suspensions of finely divided solids both show colloidal properties.

Colloidal particles are too small to be rendered visible by the ordinary microscope, but by means of the ultra-microscope Brownian movement can be observed. The fact that the particles in a colloidal solution do not separate out of the liquid is due partly to this movement, and partly to the electrical charge they carry. In some sols this charge is positive, but in the majority it is negative; in either case, the mutual repulsion of similarly charged particles tends to keep them in suspension.

It will be noted that there are two main types of colloidal solutions. Some substances, such as gelatin, acacia and agar, disperse spontaneously in water to form aqueous sols, while others, such as sulphur, ferric hydroxide and iodine, form sols only under certain conditions. These are known respectively as lyophilic and lyophobic colloids. Another respect in which these two types differ from one another is in their viscosity. Colloids having well defined lyophobic properties give sols of about the same viscosity as that of the liquid medium alone; these sols consist undoubtedly of solid particles suspended in a liquid, and are therefore known as suspensoid sols. Lyophilic colloids form sols in which it is probable that the dispersed particles contain in

Colloidal Solutions—Continued.

association a large number of molecules of the liquid, and they are much more viscous than the dispersion medium. In this respect they resemble emulsions, which are dispersions of liquids in liquids, and they are therefore known as emulsoid sols. Both systems of classification approximately correspond, but there is a gradual transition in character from the typically lyophilic or emulsoid sols to the typically lyophobic or suspensoid sols.

The majority of emulsoid sols differ from suspensoid sols in leaving on evaporation a residue which can be redispersed in water to reproduce the sol; the sols of this type are said to be "reversible." They also differ in showing a tendency to gelatinise, forming a "gel." The principal difference between the two types is, however, in their behaviour towards electrolytes. On the addition of an electrolyte, a suspensoid sol becomes unstable owing to neutralisation of the charge on the particles, and the dispersed substance is precipitated. Coagulation of a negatively charged sol is brought about mainly by the positive ion of the electrolyte and vice versa. The higher the valency of the active ion the smaller is the concentration of electrolyte required to produce coagulation. Thus, in the case of negatively charged suspensoid sols, aluminium salts are more active precipitants than calcium salts, and the latter are, in turn, more active than sodium salts. The hydrogen ion (acids) is, however, more potent than other univalent cations, and organic ions, such as those of alkaloids, are also active in comparatively low concentrations. Similarly, sulphates cause coagulation of a positively charged sol, such as solution of dialysed iron, in lower concentration than chlorides. Emulsoid sols are not readily precipitated by the addition of electrolytes. Their greater stability is connected with the presence of associated water molecules in the particles and, on the removal of the associated water by the addition of dehydrating agents such as alcohol or acetone, the particles are readily precipitated by electrolytes.

Comparatively high concentrations of very soluble salts are also able to coagulate or "salt-out" emulsoid sols, even in the absence of a dehydrating agent. According to modern theories of solution, the ions of a very soluble substance are associated with a large number of solvent molecules. Hence, on the addition of excess of a soluble salt to an emulsoid sol, the ions remove water molecules associated with the colloidal particles, thus having a dehydrating effect similar to that of alcohol, and the usual coagulating action of an electrolyte is then effective. Different ions show this dehydrating effect to different extents. The order of activity of different anions is independent of the cation and is the same for all sols. The most effective are citrates, tartrates and sulphates; iodides and thiocyanates have no "salting-out" effect, but have rather the reverse action. The most commonly used salts are the sulphates of ammonium, sodium and magnesium; ammonium sulphate is the most soluble of these, and is used for precipitating proteins in the preparations of biological products such as sera.

Colloidal Solutions—Continued.

Many emulsoid sols are stable in the presence both of acids and of alkalis. The sign of the charge varies with the pH of the medium; usually in acid solution the particles are positively charged and in alkaline solution negatively charged. At some intermediate point, usually not at pH 7, the particles are uncharged; at this point the sol exhibits its greatest instability and the disperse phase is most readily precipitated by electrolytes. The point of zero charge is known as the iso-electric point and is defined by the pH of the medium. This instability when the particles are uncharged is used, for example, in the preparation of insulin, which is precipitated between the limits corresponding to the values pH 5 and pH 6.

The charge on the particles in a colloidal solution can be neutralised by mixing oppositely charged sols. When the ratio of the volumes mixed is kept within limits, both sols may be completely coagulated; if either sol is present in large excess a stable mixed sol results, in which all the particles have a charge of the same sign as that of the colloid present in excess. Mixtures of suspensoid and emulsoid sols have largely the properties of the emulsoid type, particularly their stability in the presence of electrolytes. The coagulation of a suspensoid sol by an electrolyte can, therefore, be largely prevented by the addition of an emulsoid sol, which is said to "protect" it. The protective value of a sol, termed the "gold number," is estimated by determining the amount required to prevent coagulation of a gold sol on the addition of a given quantity of sodium chloride solution. The values obtained with a gold sol do not necessarily apply to other sols, but, in general, gelatin and isinglass are more effective than acacia, although both gelatin and acacia are commonly used in pharmaceutical preparations. The most effective protective colloids as yet obtained are decomposition products of proteins, such as gelatin or egg albumen. They are particularly useful for stabilising sols of metals, but cannot be used in medicinal sols administered by injection owing to the protein content.

Although the usual effect of the addition of an electrolyte to a suspensoid sol is to cause coagulation, some substances, especially finely divided precipitates, will disperse only in a solution of an electrolyte, forming a stable colloidal solution. The process is known as peptisation, and is utilised in pharmacy in making preparations such as solution of ferric oxychloride, which contains ferric hydroxide peptised by ferric chloride. Colloidal solutions prepared by peptisation are unstable in the presence of other electrolytes, and are coagulated if the peptising agent is removed by dialysis.

Methods of Preparing Colloidal Solutions

Many substances, particularly those giving emulsoid sols, disperse spontaneously in appropriate solvents. Gelatin, agar, starch and hæmoglobin are common examples of these, and readily disperse in water to form colloidal solutions. In general, these substances are all

Colloidal Solutions—Continued.

complex organic compounds of high molecular weight, and their colloidal nature may possibly be due to the large size of the molecule, which approaches the dimensions of typical colloidal particles. Colloidal solutions of substances which do not normally occur as colloids may be prepared by two general types of process. Ordinary gross particles may be reduced in size by mechanical means, or molecules may be made to coagulate to a limited extent to form aggregates of colloidal dimensions. The former method is applied in the apparatus known as a "colloid mill," in which a suspension of the substance required in the colloidal condition is passed between two discs rotating at high speed in opposite directions. This process may be used, for example, in the preparation of the very finely divided colloidal varieties of substances such as kaolin or calamine. The colloidal particles in a kaolin suspension may be separated without coagulating by adding an electrolyte such as sodium silicate and exposing it to an electric field. In these circumstances the silicate ions become associated with the particles of kaolin, imparting a negative charge, and the particles move to the positive electrode where they are deposited. Another example of the mechanical reduction of the size of gross particles is found in the electro-dispersion processes for preparing colloidal solutions. The original method, that of Bredig, consisted in passing an electric arc beneath the surface of water between two electrodes of the substance required in colloidal solution. Numerous modifications of this method have been introduced by means of which it is possible to prepare sols of practically any metal and of many non-metals. The addition of a protective colloid is necessary to ensure stability. The preparation of colloidal solutions by allowing molecules to coalesce usually involves chemical interaction in the presence of a large volume of liquid and of a protective colloid. The details, therefore, vary with individual substances and are considered in certain cases below.

Therapeutic Properties of Colloidal Solutions

The therapeutic value of substances in colloidal solution has been the subject of much controversy. Their use in medicine is based on the fact that the smaller size of colloidal particles, in comparison with finely powdered substances, confers on them a greater surface area and therefore a greater activity. For example, the action of sulphur depends largely upon its conversion into sulphide; this takes place most readily with colloidal sulphur and least with the crystalline variety. Colloidal kaolin also shows stronger adsorptive properties than the same substance in gross particles, owing to the larger surface area. It is also possible that, since the body tissues and vital functions are almost entirely of a colloidal nature, they are therefore more likely to respond to treatment with colloidal substances. On the other hand, it has been suggested that colloidal solutions administered by the mouth must be coagulated by contact with the digestive fluids and any special value of the colloidal

Colloidal Solutions—Continued.

condition thereby lost. It is the more difficult to assess accurately the medicinal value of a substance in colloidal solution because in some of the preparations on the market the active ingredient is not in colloidal solution, but in chemical combination with a body of colloidal nature. In the case of a number of colloidal liquids administered by injection, the therapeutic effect may be due largely to the protective colloid, which is commonly of proteid nature, the action being the same as that of substances administered in non-specific protein therapy. It is, however, probable that a number of substances in the colloidal state do possess definite therapeutic properties, and possess advantages over the same substances in the ionic or molecular condition. Practically nothing is known of their fate when introduced into the body, but it is not improbable that, although precipitated, they form a reservoir from which is liberated a small but continuous supply of the ionised substance.

Colloidal Antimony Sulphide. A colloidal solution of antimony sulphide may be prepared by saturating a dilute solution of potassium antimonyltartrate with hydrogen sulphide, removing electrolytes by dialysis, and protecting the sol thus obtained with acacia. It has been administered by injection in the treatment of various tropical diseases, but possesses no demonstrable superiority over potassium antimonyltartrate in ordinary solution.

Colloidal Calcium. Preparations of calcium in colloidal solution do not contain the metal itself in colloidal suspension, but consist of an aqueous solution of the calcium salt of an acid, such as oleic acid or glutaminic acid which is obtained by the hydrolysis of gelatin. It is sometimes administered by the mouth or by injection in the treatment of cases of calcium deficiency.

Colloidal Gold. An aqueous gold sol may be prepared by electro-dispersion methods, and stabilised with gelatin or isinglass. It may be prepared more conveniently by the chemical reduction of gold chloride in very dilute solution with formaldehyde. A gold sol is used in the examination of the cerebrospinal fluid as an aid to the diagnosis of certain pathological conditions. This test, known as the Lange reaction, consists in determining the effect of the cerebrospinal fluid in protecting the gold sol from the precipitating action of sodium chloride. In certain diseases of the central nervous system the protective activity is greatly reduced.

Colloidal Iodine. Iodine in colloidal form is stated to be produced when simple solution of iodine is added to milk. A solution of colloidal iodine may be prepared by adding solutions of iodine and of hydriodic acid to water containing acacia or gelatin. In some preparations the iodine is in combination with organic matter of colloidal nature. Colloidal iodine is administered internally in the treatment of rheumatoid arthritis and chronic rheumatism.

Colloidal Solutions—Continued.

Colloidal Iron. In colloidal solutions containing iron, the metal is frequently present as the hydroxide. Solution of dialysed iron is a ferric hydroxide sol. On account of the absence of ferric ions, this and other similar preparations are free from astringency.

Colloidal Lead, and Colloidal Lead Selenide. A colloidal solution of lead may be obtained by electrical methods and in other ways. Lead selenide is precipitated on mixing aqueous solutions of an alkali selenide and a soluble lead salt. When the precipitation is carried out in the presence of acacia, a small proportion of the precipitate remains in colloidal solution from which electrolytes may be removed by dialysis. Colloidal lead, either as the metal or in combination, has been tried in the treatment of cancer. Its use was suggested by the abortifacient action of lead, which appears to be due to its toxic action on the chorionic villi. Since it was believed that the cells of the chorionic villi have certain resemblances in growth to malignant cells, it was argued that this action of lead would be inimicable to cancer cells. Investigations of many lead-containing substances, such as colloidal lead, colloidal lead phosphate, and colloidal lead selenide, have indicated that the formation of ionic lead must be prevented if toxic effects are to be avoided. The preparation is administered intravenously; the total dosage which should be given is from 0.5 to 0.8 gramme of metallic lead. Liver and kidney functions should be examined carefully before lead is administered, and during treatment, since it is on these organs that the brunt of the toxic action of the metal falls. Cases exhibiting a failing heart muscle or a severe degree of anæmia are obviously unsuitable for lead therapy. Lead treatment may be combined with X-ray or radium therapy, though some observers have called attention to the danger of combining treatment by a selenium-lead compound with exposure to radium. No satisfactory chemotherapeutic measure has yet been discovered for the treatment of cancer, although it is possible to some extent to inhibit the growth of certain malignant tumours by means of colloidal lead.

Colloidal Manganese. A colloidal solution of manganese hydroxide may be obtained by mixing solutions of manganese chloride and sodium hydroxide in the presence of dextrose. It has been administered by injection in the treatment of boils and other staphylococcal infections.

Colloidal Silver. A colloidal solution of silver may be prepared by electro-dispersion methods, and stabilised by gelatin or an alkaline solution of egg albumen. A 1 per cent. colloidal silver solution may also be prepared by reducing silver nitrate with a solution of ferrous sulphate and sodium citrate, or by adding ammonia solution gradually to silver nitrate solution until the precipitate first formed is just re-dissolved, and reducing the product with tannic acid, formaldehyde, or hydrogen; a protective colloid must be added. Colloidal silver is used in a strength of 1 in 2000 as a non-irritant antiseptic in the treatment

Colloidal Solutions—Continued.

of infections of mucous membranes. Some colloidal preparations of silver contain the metal in combination with compounds obtained by the degradation of proteins; such, for example, are silver proteinate and mild silver proteinate.

Colloidal Sulphur. A colloidal sulphur solution may be obtained by adding sulphuric acid to a solution of sodium thiosulphate in the presence of gelatin or acacia. It is used internally in the treatment of rheumatic affections. Externally, colloidal sulphur has been used for the treatment of various skin diseases.

APPENDIX XII

Sterilisation

Solutions and suspensions for injection or for application to mucous membranes, such as the conjunctiva, should be sterile, that is, free from living micro-organisms. The methods used to kill or remove the micro-organisms may involve the application of dry or moist heat, the use of chemical substances, filtration, or a combination of these methods. The method chosen must be one which does not inactivate the medicament or render the preparation unsuitable for the particular purpose for which it is intended.

Temperature has a very marked effect on bacterial development; in the case of pathogenic bacteria, the optimum temperature for their growth is about 37° , but growth may occur at much lower and at slightly higher temperatures than this. The minimum temperature which is fatal to an organism is known as the thermal death point (T.D.P.). For non-sporing bacteria and for the vegetative forms of sporing bacteria it is considerably lower than for spores, and is lower in the presence of moisture than in its absence. In the latter condition the spore capsules are not hydrated and therefore, when the temperature is raised, they do not swell, rupture and permit escape and destruction of the protoplasm. Whilst the T.D.P. may vary with the different types of bacteria, no non-sporing forms can survive a temperature of 80° when maintained for thirty minutes. In steam under pressure, a temperature of 115° to 116° maintained for thirty minutes is fatal to all spore forms, but in the dry condition 150° for one hour is necessary. The T.D.P. may be lowered by the presence of an antiseptic such as phenol. When sterile preparations for injection are dispensed in bulk in such a manner as to permit the withdrawal of several doses, an antiseptic, such as 0.5 per cent. w/v of phenol, is added so that, should re-infection occur, the development of the bacteria will be inhibited.

Sterilisation by heat is generally the most suitable and convenient method, but it can only be applied if the medicament is thermostable. When the substance is not thermostable, filtration is usually adopted, but the preparations must then be submitted subsequently to the tests for sterility before being used for injection.

The preparation of sterile solutions and material necessitates the adoption of rigid *aseptic methods* which involve as far as possible the exclusion of bacteria from the product prior to the final sterilising operation. Such precautions greatly facilitate sterilisation and sometimes constitute the only method that can be adopted. Sterile solvents and containers should always be used. The dispenser should observe precautions of personal cleanliness, such as the wearing of a clean overall and disinfection of the hands by washing in an antiseptic solution, etc. The operations should be carried out in a room which is

Sterilisation—Continued.

as dust-free as possible and which is not subject to air-currents. All glass apparatus should be well cleaned in hot soapy water or, if new, with a mixture of sulphuric acid, 46 parts by volume, potassium dichromate, 6 parts, and water, 46 parts, and subsequently well washed with distilled water.

Chemicals which can replace phenol as antiseptics include chlorbutol and cresol, in a minimum concentration of 1 in 200. The presence of sodium chloride is considered to increase the potency of phenol and cresol as antiseptics, and low temperature sterilisation, that is between 70° and 100°, of an injection containing phenol probably produces a sterile preparation with greater certainty than when an antiseptic is absent from the solution. Phenol may reduce the efficiency of tyndallisation since it prevents the development of spores into vegetative bacteria.

Methods of Sterilisation

Heating in an Autoclave.—Whenever possible, solutions to be sterilised should be heated in steam under pressure. This can be carried out efficiently by means of an autoclave. A temperature of 115° to 116° for thirty minutes, which involves a pressure of 10 pounds per square inch in excess of atmospheric pressure when the autoclave is filled with steam, is sufficient to kill all bacteria and spores. This method may be used for sterilising apparatus and aqueous solutions of substances which are not damaged at the temperatures stated. Care must be taken to ensure that all air is removed from the autoclave by blowing steam through before finally closing it down. Bottles containing solutions to be sterilised in the autoclave should have well-fitting stoppers, or the stopper may be replaced by a plug of non-absorbent cotton wool covered with transparent cellulose tissue or with a small glass dish. The stoppers, if sterilised separately, should be replaced aseptically.

Where the volume of the liquid to be sterilised exceeds 100 millilitres, more than thirty minutes is necessary in order to ensure that the whole of the solution has been maintained at 115° to 116° for thirty minutes. At the expiration of the time, the source of heat should be removed and the pressure allowed to fall to normal before opening the autoclave. When two or more containers holding different solutions are autoclaved together, each container should be marked so as to ensure its recognition after removal from the autoclave. Solutions supplied in bottles with rubber caps are sterilised by heating the solution in the plugged bottles for the specified time, allowing the temperature to fall to 100°, removing the bottles and placing the sterilised cap over the necks. The rubber caps may be sterilised by boiling for thirty minutes in a sterilised 2 per cent. solution of phenol and stored in the solution in which they have been boiled.

The following table shows the temperatures corresponding to various pressures of steam:—

Sterilisation—Continued.

Pressure of Steam in excess of Atmospheric Pressure	Corresponding Temperatures	
	Centigrade	Fahrenheit
5 lb. per sq. inch	109°	228°
10 lb. per sq. inch	115·5°	240°
15 lb. per sq. inch	121°	250°
20 lb. per sq. inch	126°	259°
25 lb. per sq. inch	130·5°	267°
30 lb. per sq. inch	134·5°	274°

Dry Heat.—Sterilisation by means of dry heat is carried out in a hot air oven, the temperature of which is controlled by a thermostat or by adjustment of the source of heat. Apparatus, etc., subjected to dry heat requires a higher temperature for efficient sterilisation than when moisture is present. Small pieces of apparatus, ampoules and vials should either be wrapped in paper or placed in lightly covered tins, before they are subjected to the action of heat. Flasks, test tubes, measures and bottles should be plugged with non-absorbent cotton wool, covered not too tightly with paper or transparent cellulose tissue, the covering being tied in position. Heat should be applied gradually to the oven, and sterility is ensured by maintaining a temperature of 150° for one hour. Care must be taken not to open the door of the hot air oven while the temperature inside is still high.

This method of sterilisation may be used for fixed oils, glycerin, liquid, hard and soft paraffins, waxes, and powders, such as kaolin, purified talc and zinc oxide, which should be spread out in thin layers. In the preparation of a solution or a suspension which would undergo a chemical or physical change at 150°, the vehicle should first be sterilised in the hot air oven, and the solution or suspension made by aseptic methods, with the addition of phenol or other antiseptic. If thermostable, the finished product should be sterilised by tyndallisation or by heating at 100° for thirty minutes unless it contains sufficient antiseptic to maintain it in a sterile condition.

Tyndallisation.—Tyndallisation, or the intermittent heating of preparations at temperatures between 60° and 80°, is a method of sterilisation which depends for its result on the killing of bacteria in the vegetative form during the first heating, and the inducement of spores to germinate, rendering them susceptible to the action of heat on subsequent days. The process of tyndallisation of the British Pharmacopœia requires the material to be heated at 80° for one hour on three successive days and, unless otherwise stated, this temperature is maintained in the sterilisation by tyndallisation of substances of the British Pharmaceutical Codex. The material to be sterilised must be in sealed containers, ampoules, or bottles, and the most convenient

Sterilisation—Continued.

form of apparatus consists of a water-bath fitted with a gas or electric regulator so that the desired temperature may be maintained. It is convenient to add a small quantity of dye, such as methylene blue, to the water in the bath as an indicator of leakage between the product being sterilised and the water. Any leakage will be shown on allowing the container to cool, without removing it from the bath, by the entry of some of the coloured water. In the case of large volumes of material, for example, bottles containing more than 100 millilitres, heating may be necessary for a period longer than one hour in order to maintain the contents at that temperature for the specified period.

In the process of tyndallisation, absolute sterility can only be obtained if relatively clean material is used in making the preparation; the greatest care is therefore necessary in sterilising the apparatus and the medium used in making the product. It has been shown that tyndallisation is not reliable unless controlled by subsequent tests for sterility.

Filtration.—Sterilisation by filtration consists in passing the material to be sterilised through filters made of fine, unglazed porcelain (Chamberland or Doulton), or of diatomite (Berkefeld), or pads of compressed asbestos (Seitz). The selected bacteria-proof filter is first sterilised by heating in an autoclave at 115° to 116° for thirty minutes, or in a steam steriliser for one hour on three successive days. When required for use it is attached to a filter flask which has been sterilised in the manner described for the filter, the steam having been admitted to the flask through an air filter, and is connected to a suction pump, all the joints being completely air-tight. On the completion of sterilisation, the filtrate is distributed aseptically into sterile ampoules which are then sealed, or into sterile rubber-capped bottles. All materials sterilised by filtration must comply with tests for sterility before being used. If an asbestos pad filter is used, a small quantity of sterilised water should first be passed through it so as to remove any adherent particles and any soluble matter which may be present. The pad is subsequently dried by suction. After use, the filter, if of the diatomite or porcelain type, should be cleaned carefully by scrubbing and then passing through it an antiseptic solution such as a 0.5 per cent. solution of potassium permanganate followed by a 5 per cent. solution of sodium pyrosulphite; the candle should then be washed with distilled water and sterilised in the ordinary way before further use.

Emergency Method.—When possible, preparations for injection should be sterilised by heating in an autoclave, by tyndallisation, by filtration, or by heating at 150° for one hour. In an emergency, preparations may be made as follows:—All the apparatus used is sterilised by heating in an autoclave or by heating at 150° for one hour and should be kept ready for use. If the solvent is distilled water, it is sterilised by heating in an autoclave or by boiling for thirty minutes, or if a fixed

Sterilisation—Continued.

oil, by heating at 150° for one hour. The injection is prepared and 0.5 per cent. w/v of phenol or other equally effective antiseptic is added, and the previously sterilised final containers are then filled and sealed. The containers are immersed in water which is heated to 80° and kept at that temperature for thirty minutes. If the solution is thermostable at 100°, the containers may be kept in boiling water for thirty minutes. Solutions prepared in this manner are labelled to show the date and the warning, "Keep in a cool place and use within four days." If the solutions are required for intravenous injection, no antiseptic is added, and after the solution has been prepared by aseptic methods it is boiled for fifteen minutes. The emergency method is applicable to those substances which may be sterilised by heating in an autoclave or by tyndallisation, but cannot be used for substances for which the method of filtration alone is recommended. Solutions for intrathecal injection must not be prepared by the emergency method. In any emergency in which the methods described above cannot be applied, it is the duty of the dispenser to inform the prescriber that complete sterilisation cannot be attempted, and to obtain the prescriber's approval for the method to be adopted.

Steaming.—Steaming consists of exposing the aqueous solution to steam at atmospheric pressure in a steamer similar to a Koch's steriliser for a period of one hour after the solution has attained the temperature of the steam. This method has been shown to produce sterile products with aqueous solutions of the following substances:—atropine sulphate, caffeine and sodium benzoate, calcium chloride, codeine phosphate, dextrose, morphine hydrochloride, morphine tartrate, peptone, phenazone, pilocarpine nitrate, procaine hydrochloride, sodium chloride, sodium salicylate, sodium thiosulphate, soluble barbitone, strychnine hydrochloride.

Sterilisation of Dressings

The sterilisation of surgical dressings may be effected by heating them in steam, in apparatus and under conditions similar to those outlined below. The sterilising apparatus consists of three essential parts, namely: (1) a cylindrical sterilising chamber constructed to withstand steam pressure; (2) a steam jacket surrounding this chamber, also constructed to withstand steam pressure; (3) a drying or heating chamber with direct connection to the jacket and consequently subject to the same steam pressure, containing a set of coils through which steam is introduced into the sterilising chambers. An air extractor is also provided, usually of a steam-operated type, capable of maintaining a vacuum for the purpose of extracting air or steam from the sterilising chamber, and suitable gauges are provided to denote the pressures and vacuum in the chamber and jacket. The process of sterilisation consists in exposing the dressings to saturated steam under pressure, and afterwards to hot air, and takes place in the sterilising chamber, which

Sterilisation--*Continued.*

has two doors, one for use in charging with dressings and the other for withdrawal after the process. Steam is first admitted to the jacket until a suitable pressure is reached. The dressings are then placed in the inner chamber, the doors are closed, and air is extracted until an efficient vacuum is obtained, at which point the extractor is closed. Steam is drawn from the drying or heating chamber, passed through a reducing valve for the purpose of reducing it to a pressure lower than that in the drying chamber, then passed through the coils in the latter, where it is heated sufficiently to remove any condensate, and then into the sterilising chamber until the desired pressure is reached and maintained for a sufficient length of time. The steam is then blown off to atmospheric pressure, extracted by vacuum and finally air is drawn by means of the extractor through the sterilising chamber after first having been heated to a suitable temperature by passing through the coils in the heating chamber. This effectively dries the dressings, completing the operation.

The exact steam pressures, degrees of vacuum and process times depend on the nature of the dressings. Small, loosely packed dressings, for example, six-yard rolls of gauze, are found to be sterilised efficiently by thirty minutes' treatment at 10 pounds steam pressure (116°) in the sterilising chamber, the pressure in the jacket being 15 pounds (120°), the vacuum 10 inches and the air heated to 120° , the air drying process continuing for fifteen minutes. Larger or more tightly packed dressings require modification of the above directions, such as longer process times and higher pressures. In order to ensure that the temperature required has been reached during the process of sterilisation, an indicator consisting of a dye, such as methylene blue, in the proportion of 0.1 per cent. of another substance melting at the required temperature, may be inserted in a tube placed in the centre of the dressing. The following substances may be used:—sulphur (melting-point, 115°); acetanilide (melting-point, 113°); terpin hydrate (melting-point, 116°); benzoic acid (melting-point, 121°).

Surgical dressings cannot be sterilised by dry heat, nor are chemical methods suitable for ensuring the absolute sterility of such substances as cotton wool, lint, gauze, etc. Surgical ligature (e.g. catgut) and surgical suture (e.g. horse-hair) are sterilised by boiling under a reflux condenser in alcohol, benzene, or acetone, or by treatment with chromium sulphate and mercuric chloride. Before being issued for use every batch of surgical ligature and suture must comply with tests for sterility.

Rubber gloves, tubing and apparatus are sterilised by boiling with water, or by heating in steam at a temperature of 109° for one hour. Surgical instruments, such as surgeon's knives, forceps, hypodermic syringes and needles, are kept in a sterile condition by storage in solution of cresol with soap (2 per cent. v/v in distilled water) or in alcohol (95 per cent.). Before use they should be washed with sterilised water or with a dilute antiseptic. After use they may be sterilised by

Sterilisation—Continued.

heating in boiling water to which is added borax, 1 per cent., or sodium carbonate, 2 per cent.

Tests for Sterility

Solutions for injection which have been sterilised by filtration are tested for sterility by the inoculation and subsequent incubation of tubes of sterile broth. The broth should contain 1 per cent. of peptone and its reaction must lie between pH 7·2 and pH 7·8.

Not less than 0·1 per cent. of the total volume of the solution to be tested is taken where the volume is not more than 10 litres. If the volume is 10 litres or more, then not less than 10 millilitres is used. When samples are taken from bulk containers, these proportions should be taken from each of the containers and tested separately. When samples are taken from ampoules, not less than 1 per cent. of the total, if the batch does not exceed 1000, and not less than 10 containers, if the total number is more than 1000, are used to inoculate the broth. The tubes of broth are incubated at 37° for five days, one half of the total volume of the sample being used for the aerobic and one half for the anaerobic test. If, at the end of five days, no growth of micro-organisms is visible, the solution may be used for injection. When a growth is visible, further samples are taken and the tests repeated, and if necessary, at the end of a further five days the test is again repeated. If the same organism is visible in more than one test, the batch is regarded as not sterile, and the material is not issued until it has been re-sterilised and has passed the tests.

APPENDIX XIII

Pharmacological Index

A list of the more important drugs, classified in accordance with their pharmacological action or their use for a specific effect in certain diseases.

Preparations of the drugs, except in special cases, are not included; they may be ascertained conveniently from the summary at the end of each monograph.

Absorbents.—Substances used for the absorption of irritating secretions or for the adsorption of gaseous products or toxins in the alimentary canal.

External (Protective).—

Amylum; Bismuthi Subchloridum; Talcum Purificatum; Zinci Oxidum.

Internal.—Toxins:

Carbo; Creta; Kaolinum.

Gaseous Products:

Carbo.

Alkaloidal poisons:

Carbo; Kaolinum.

Anæsthetics.

General.—Substances producing loss of sensation and of consciousness by their depressant effect on the cerebral and spinal centres. Æther Anæstheticus; Æthylenum; Æthylis Chloridum; Chloroformum; Nitrogenii Monoxidum; Tribromethyl Alcohol.

Local.—Substances which destroy the sense of pain by preventing the conduction of impulses by nerves.

Æthylis Bromidum; Æthylis Chloridum; Amydricainæ Hydrochloridum; Amylocainæ Hydrochloridum; Benzinæ Hydrochloridum; Benzinæ Lactas; Benzocaina; Cocaina; Orthocaina; Procainæ Hydrochloridum; Quininæ et Ureæ Hydrochloridum.

Spinal.—Substances which, when injected into the spinal fluid, produce anæsthesia of the lower limbs or of part of the trunk by a local action on posterior roots or spinal cord.

Amylocainæ Hydrochloridum; Procainæ Hydrochloridum.

Surface.—Substances which produce anæsthesia when applied to mucous surfaces.

Cocaina (and its salts).

Analgesics or Anodynes.—Substances which relieve pain, either by direct action on the brain, or on nerve endings.

Pharmacological Index—Continued.

General.—Substances which relieve pain by their action on the sensory area of the cerebral cortex.

Acetanilidum; Acidum Acetylsalicylicum; Amidopyrina; Calcii Acetylsalicylas; Colchicina; Hyoscinae Hydrobromidum; Lithii Acetylsalicylas; Lithii Salicylas; Methylacetanilidum; Morphina; Opium; Papaveretum; Phenacetinum; Phenazoni Salicylas; Phenazonum; Quininae Acetylsalicylas; Quininae Salicylas; Salicinum; Sodii Salicylas.

Local.—Substances which relieve superficial pain by their depressant effect on sensory nerve endings.

Aconiti Folium; Aconitina; Aconitum; Belladonnae Radix; Benzaminae Hydrochloridum; Benzaminae Lactas; Camphora; Chloralis Hydras; Chlorbutol; Eugenol; Menthol; Methylis Salicylas; Oleum Caryophylli; Orthocaina; Phenol. (See also Local Anæsthetics.)

Anaphrodisiacs.—Substances which lessen sexual desire.

Acidum Hydrobromicum Dilutum (and bromides); Belladonnae Folium; Belladonnae Radix; Camphora; Conii Folium; Conii Fructus; Hyoscinae Hydrobromidum; Hyoscyaminae Hydrobromidum; Hyoscyamus; Stramonium.

Anhidrotics.—Substances which diminish profuse perspiration.

Local.—Acidum Aceticum Dilutum; Alcohol; Alumen; Aluminii Acetas; Aluminii Chloridum; Chromii Trioxidum; Liquor Formaldehydi; Trinitrophenol; Zinci Oxidum.

Internal.—Acidum Agaricum; Acidum Camphoricum; Atropina; Belladonnae Folium; Belladonnae Radix; Hyoscyamus; Picrotoxinum; Stramonium; Zinci Oxidum.

Antacids.—Substances which reduce excessive acidity of the gastric secretions and maintain the alkali reserve of the blood.

Diminish the acidity of the gastric contents.—Aluminii Hydroxidum; Bismuthi Carbonas; Bismuthi Hydroxidum; Calcii Carbonas; Calcii Hydroxidum; Calcii Phosphas; Creta; Magnesii Carbonas Levis; Magnesii Carbonas Ponderosus; Magnesii Hydroxidum; Magnesii Oxidum Leve; Magnesii Oxidum Ponderosum; Magnesii Phosphas; Potassii Bicarbonas; Sodii Bicarbonas.

Increase the alkalinity of the blood.—Dextrosum; Potassii Acetas; Potassii Citras; Sodii Acetas; Sodii Citras; Sodii et Potassii Tartras.

Anthelmintics.—Substances which destroy worms (vermicides) or cause their expulsion (vermifuges).

Hook-worm.—Betanaphthol; Carbonei Tetrachloridum; Oleum Chenopodii; Tetrachlorethyleneum; Thymol.

Pharmacological Index—Continued.

Round-worm.—Buteæ Semen; Carbonei Tetrachloridum; Cucurbita; Hexyl-resorcinol; Hydrargyri Subchloridum; Naphthaleni Tetrachloridum; Naphthalenum; Oleum Chenopodii; Oleum Terebinthinæ; Santoninum; Spigelia; Tetrachlorethylum.

Tape-worm.—Areca; Cucurbita; Cusso; Extractum Filicis; Granati Radicis Cortex; Kamala; Naphthaleni Tetrachloridum; Naphthalenum; Oleum Terebinthinæ; Pelletierinæ Tannas.

Thread-worm.—

Cathartic.—Hydrargyri Subchloridum; Magnesii Sulphas; Oleum Ricini; Sodii Sulphas.

Rectal irrigation.—Acidum Tannicum; Alumen; Calcii Hydroxidum; Ferri Sulphas; Oleum Terebinthinæ; Quassia; Quinina Bisulphas; Sodii Chloridum.

Internal.—Calcii Permanganas; Carbonei Tetrachloridum; Ferri Sulphas; Oleum Chenopodii; Santoninum; Sulphur; Thymol.

Antipyretics.—Substances which reduce the temperature in fever by their action on the heat-regulating centre.

Acetanilidum; Acidum Acetylsalicylicum; Amidopyrina; Calcii Acetylsalicylas; Cinchona; Lithii Acetylsalicylas; Phenacetinum; Phenazonum; Quinina; Quinina Acetylsalicylas; Quinina Disalicylosalicylas; Salicinum; Sodii Salicylas.

Antiseptics and Disinfectants.—Substances which inhibit the growth of, or destroy, micro-organisms.

For general use.

Solid.—Calcii Oxidum; Calx Chlorinata; Naphthalenum.

In solution (for utensils, excreta, bedding, etc.).—

Hydrargyri Perchloridum; Liquor Cresolis Saponatus; Phenol; Zinci Chloridum.

Gaseous (for sick rooms, etc.).—

Chlorine; Cresol (vapour); Paraformaldehydum (vapourised); Phenol; Sulphur (ignited); Sulphur Dioxide.

For local application.

To sterilise the skin before operation.—

Acriflavina; Alcohol; Hexyl-resorcinol; Hydrargyri et Potassii Iodidum; Hydrargyri Oxycyanidum; Hydrargyri Perchloridum; Iodum; Liquor Cresolis Saponatus; Mercurchromum; Methylviola; Phenol; Trinitrophenol; Viride Nitens.

Pharmacological Index—Continued.*For skin diseases.—*

Acidum Boricum; Acidum Salicylicum; Acidum Sulphurosum; Acriflavina; Argenti Nitras; Argenti Proteinæ; Benzenum; Betanaphthol; Bismuthi Tribromphenas; Chloramina; Chromii Trioxidum; Chrysarobinum; Dichloramina; Hydrargyri Iodidum Rubrum; Hydrargyri Perchloridum; Hydrargyrum Ammoniatum; Ichthammol; Iodoformum; Iodum; Liquor Calcis Sulphuratæ; Liquor Formaldehydi; Liquor Hydrogenii Peroxidi; Magenta; Mercurchromum; Methylthioninæ Chloridum; Phenol; Pix Carbonis; Pix Liquida; Proflavina; Pyrogallol; Resorcinol; Rubrum Scarlatinum; Sulphur Præcipitatum; Trinitrophenol; Viride Malachitum; Viride Nitens.

For the eye.—

Acidum Boricum; Æthylhydrocupreinæ Hydrochloridum; Argenti Nitras; Argenti Proteinæ; Cupri Sulphas; Hydrargyri et Zinci Cyanidum; Hydrargyri Oxidum Flavum; Hydrargyri Oxycyanidum; Ichthammol; Potassii Hydroxyquinolini Sulphas; Zinci Sulphas.

For the nose.—

Acidum Boricum; Argenti Proteinæ; Borax; Camphora; Liquor Hydrogenii Peroxidi; Menthol; Oleum Eucalypti; Thymol.

For the mouth and throat.—

Acidum Boricum; Argenti Nitras; Argenti Proteinæ; Chloramina; Chromii Trioxidum; Eugenol; Gargarium Chlori; Hydrargyri Perchloridum; Liquor Calcis Chlorinatæ; Liquor Cresolis Saponatus; Liquor Hydrogenii Peroxidi; Liquor Sodæ Chlorinatæ Chirurgicæ; Phenol; Potassii Chloras; Potassii Permanganas; Sodii Perboras; Thymol; Viride Malachitum; Viride Nitens; Zinci Chloridum.

For the urethra and bladder.—

Acriflavina; Argenti Nitras; Argenti Proteinæ; Hydrargyri Oxycyanidum; Mercurchromum; Potassii Hydroxyquinolini Sulphas; Potassii Permanganas; Proflavina; Viride Malachitum; Viride Nitens; Zinci Sulphas; Zinci Phenolsulphonas.

For the vagina.—

Acidum Boricum; Acriflavina; Argenti Proteinæ; Glycerinum; Hexyl-resorcinol; Hydrargyri Oxycyanidum; Hydrargyri Perchloridum; Ichthammol; Liquor Cresolis Saponatus; Magenta; Mercurchromum; Methylthioninæ Chloridum; Phenol; Potassii Permanganas; Trinitrophenol; Zinci Phenolsulphonas.

For the rectum.—

Acriflavina; Argenti Nitras; Argenti Proteinæ; Potassii Permanganas.

Pharmacological Index—Continued.*For open wounds.—*

Acidum Boricum; Acriflavina; Euflavina; Hydrargyri et Zinci Cyanidum; Hydrargyri Iodidum Rubrum; Hydrargyri Perchloridum; Ichthammol; Liquor Hydrogenii Peroxidi; Liquor Sodæ Chlorinatæ Chirurgicæ; Potassii Permanganas; Trinitrophenol; Zinci Sulphas.

*For internal administration.**Stomachic.—*

Creosotum; Oleum Cubebæ; Resorcinol.

Intestinal.—

Acidum Acetylsalicylicum; Betanaphthol; Bismuthi Salicylas; Creosotum; Euflavina; Guaiacol; Hydrargyri Perchloridum; Hydrargyri Subchloridum; Lac Coactum; Phenol; Potassii Guaiacolsulphonas; Salol; Thymol. (See also Cathartics.)

Urinary.—

(i) Ammonii Benzoas; Buchu; Copaiba; Cubeba; Hexamina; Hexyl-resorcinol; Lithii Benzoas; Methylthioninæ Chloridum; Oleum Cubebæ; Oleum Juniperis; Oleum Santali; Salol; Sodii Benzoas.

(ii) (*to render the urine acid*): Acidum Hydrochloricum Dilutum; Ammonii Benzoas; Ammonii Chloridum; Ammonii Nitras; Sodii Phosphas Acidus.

(iii) (*to render the urine alkaline*): Magnesii Hydroxidum; Potassii Bicarbonas; Potassii Citras; Sodii Acetas; Sodii Bicarbonas; Sodii Citras; Sodii et Potassii Tartras.

Respiratory.—

Creosotum; Cubeba; Potassii Guaiacolsulphonas; Terebenum.

For intravenous injection.—

Hydrargyri Perchloridum; Mercurochromum; Neoarsphenamina; Viola Crystallina.

Antispasmodics.—Substances used to relieve spasmodic muscular contractions.

Respiratory.—

Adrenalina; Amylis Nitris; Atropina; Belladonna; Benzylis Benzoas; Chloroformum; Codeina (and its salts); Diamorphinæ Hydrochloridum; Ephedrina (and its salts); Hyoscyamus; Lobelia; Stramonium.

Intestinal.—

Atropina; Belladonna; Diamorphinæ Hydrochloridum; Codeina (and its salts); Hyoscina; Hyoscyamina; Hyoscyamus; Morphina (and its salts); Opium.

Aperients.—See Cathartics.

Pharmacological Index—Continued.

Aphrodisiacs.—Substances which increase sexual desire.

Alcohol; Cannabis; Cantharidinum; Damiana; Nux Vomica; Phosphorus; Strychnina; Yohimbina.

Astringents.—Substances which tend to contract mucous membranes and raw surfaces.

By constriction of the arterioles.—Adrenalina; Ephedrina.

By absorption of water.—Glycerinum.

By the precipitation of protein in the superficial cells.

Internal.—Acetannin; Acidum Sulphuricum Dilutum; Aluminii Hydroxidum; Bismuthi Carbonas; Bismuthi Subnitras; Bismuthi Tannas; Catechu; Catechu Nigrum; Cinchona; Cinnamomum; Creta; Guarana; Hæmatoxylum; Kino Eucalypti; Krameria; Opium; Plumbi Acetas; Quercus.

External.—Acidum Lacticum; Acidum Tannicum; Alumen; Alumen Ferricum; Aluminii Acetas; Aluminii Hydroxidum; Argenti Nitras; Bismuthi Carbonas; Bismuthi Subgallas; Bismuthi Subnitras; Calamina; Calcii Hydroxidum; Cupri Sulphas; Ferri Perchloridum; Galla; Hamamelis; Kino; Kino Eucalypti; Krameria; Plumbi Acetas; Plumbi Carbonas; Plumbi Oleas; Potassii Chloras; Zinci Carbonas; Zinci Chloridum; Zinci Oxidum; Zinci Phenolsulphonas; Zinci Sulphas.

Carminatives.—Substances which relieve flatulence, and produce a feeling of warmth and comfort in the stomach.

Æther; Alcohol; Anethum; Anisum; Anthemis; Aurantii Cortex; Camphora; Capsicum; Cardamomum; Carum; Caryophyllum; Cassiæ Cortex; Chloroformum; Cinnamomum; Coriandrum; Cuminum; Fœniculum; Menthol; Myristica; Oleum Anethi; Oleum Anisi; Oleum Anthemidis; Oleum Cari; Oleum Caryophylli; Oleum Cinnamomi; Oleum Coriandri; Oleum Fœniculi; Oleum Lavandulæ; Oleum Menthæ Piperitæ; Oleum Menthæ Viridis; Oleum Myristicæ; Pimenta; Zingiber.

Cathartics.—Substances which assist or induce evacuation of the bowel.

Cholagogues.—Substances which increase the secretion or flow of bile.

• Acidum Nitro-hydrochloricum Dilutum; Acidum Oleicum; Fel Bovinum; Hydrargyri Subchloridum; Magnesii Sulphas; Oleum Olivæ; Podophylli Resina; Sapo Durus; Sodii Salicylas; Sodii Tauroglycocholas.

Laxatives.

Cassiæ Fructus; Euonymus; Ficus; Sulphur Præcipitatum; Sulphur Sublimatum; Tamarindus.

Pharmacological Index—Continued.

Softening and bulk producing.—Agar; Ispaghula; Linum; Paraffinum Liquidum; Paraffinum Molle; Psyllium; Tragacantha.

Saline Aperients.—Magnesii Carbonas Levis; Magnesii Carbonas Ponderosus; Magnesii Hydroxidum; Magnesii Oxidum Leve; Magnesii Oxidum Ponderosum; Magnesii Sulphas; Potassii Tartras Acidus; Sodii et Potassii Tartras; Sodii Phosphas; Sodii Sulphas.

Acting on the colon.—Aloe; Aloinum; Cascara Sagrada; Rheum; Sennæ Folium; Sennæ Fructus.

Acting on the small intestine.—Oleum Ricini; Phenolphthaleinum.

Drastic Purgatives.

Aloe; Aloinum; Cambogia; Colocynthis; Hydrargyri Subchloridum; Hydrargyrum; Ipomœa; Jalapa; Jalapæ Resina; Jalapin; Kaladana; Leptandra; Magnesii Sulphas; Oleum Crotonis; Oleum Ricini; Podophylli Resina; Podophyllum; Scammoniae Resina; Turpethum.

By hypodermic injection.—Ergotoxina; Extractum Pituitarii Liquidum; Physostigmina

Per rectum.—Fel Bovinum; Glycerinum; Oleum Olivæ; Sapo Durus.

Caustics.—Substances which destroy living tissues to which they are applied.

By consuming the tissue.—Acidum Aceticum Glaciale; Acidum Hydrochloricum; Acidum Nitricum; Acidum Salicylicum; Acidum Sulphuricum; Acidum Trichloroaceticum; Calcii Oxidum; Chromii Trioxidum; Potassii Hydroxidum; Sodii Hydroxidum.

By precipitation of protein.—Alumen Exsiccatum; Aluminii Sulphas; Argenti Nitras; Cupri Nitras; Cupri Subacetat; Cupri Sulphas; Liquor Antimonii Chloridi; Phenol; Zinci Chloridum.

By inflammation, producing a slough.—Carbonei Dioxidum (solid).

Cholagogues.—See Cathartics.

Counter-irritants.—Substances which, on local application, stimulate nerve endings and produce vasodilation.

Rubefacients.—Acidum Aceticum; Alcohol; Ammonia (Solution); Camphora; Cantharidinum; Cantharis; Capsicum; Chloroformum; Eucalyptol; Methylis Salicylas; Oleum Cajuputi; Oleum Camphoræ Rectificatum; Oleum Myristicæ; Oleum Sassafras; Oleum Sinapis Volatile; Oleum Succini; Oleum Terebinthinæ; Oleum Thymi; Sinapis.

Pharmacological Index—Continued.

Vesicants.—Substances which cause inflammation and produce a blister.

Cantharidinum; Cantharis; Carbonei Dioxidum (solid); Oleum Crotonis; Oleum Sinapis Volatile; Sinapis.

Demulcents.—Substances which have a soothing and protective action on mucous membranes.

Acacia; Agropyrum; Althæa; Amygdala Dulcis; Cetraria; Chondrus; Gelatinum; Glycerinum; Glycyrrhiza; Linum; Maranta; Mel Depuratum; Oleum Amygdalæ; Oleum Arachis; Oleum Olivæ; Oleum Sesami; Tragacantha; Tussilaginis Flos; Ulmus Fulva.

Deodorants.—Substances which counteract fœtid smells. (See also Antiseptics.)

Aluminii Acetas; Calx Chlorinata; Carbo; Chromii Trioxidum; Creosotum; Cresol; Guaiacol; Liquor Formaldehydi; Liquor Hydrogenii Peroxidi; Oleum Eucalypti; Oleum Picis; Potassii Permanganas; Sodii Perboras; Terebenum; Thymol.

Depilatories.—Substances used for the removal of hair.

Local application.—Baryta Sulphurata; Calx Sulphurata.

Internal administration.—Thallii Acetas.

Diaphoretics.—Substances which induce sweating.

Aconitum; Alcohol; Ammonii Acetas; Ammonii Chloridum; Ammonii Citras; Antimonii et Potassii Tartras; Antimonii Trioxidum; Apomorphinæ Hydrochloridum; Camphora; Ipecacuanha; Opium; Physostigmina; Pilocarpina; Potassii Citras; Quininæ Disalicyclosalicylas; Sodii Salicylas; Spiritus Ætheris Nitrosi.

Digestives.—Substances which assist the normal process of digestion.

Diastasum; Extractum Malti; Pancreatinum; Papainum; Pepsinum.

Disinfectants.—See Antiseptics.

Diuretics.—Substances which increase the renal secretion.

Saline.—Ammonii Acetas; Ammonii Chloridum; Ammonii Citras; Ammonii Nitras; Ammonii Phosphas; Lithii Carbonas; Lithii Chloridum; Lithii Citras; Potassii Acetas; Potassii Bicarbonas; Potassii Citras; Potassii Nitras; Potassii Tartras; Potassii Tartras Acidus; Sodii Acetas; Sodii Benzoas; Sodii Citras; Sodii Formas.

Pharmacological Index—Continued.

Kidney Irritants.—Agropyrum; Buchu; Copaiba; Cubeba; Guaiaci Resina; Kava; Oleum Juniperi; Oleum Santali; Oleum Terebinthinæ; Scoparium; Uva Ursi.

Cardiac.—Convallaria; Digitalis; Scilla; Strophanthus.

Purine derivatives.—Caffeina; Theobromina; Theobromina et Sodii Salicylas; Theophyllina et Sodii Acetas.

Mercurial.—Hydrargyri Subchloridum; Hydrargyrum.

Intravenous injection.—Dextrosum; Sodii Bicarbonas; Sodii Carbonas; Sodii Chloridum.

Emetics.—Substances which cause vomiting.

Alumen; Antimonii et Potassii Tartras; Apomorphinæ Hydrochloridum; Cupri Sulphas; Emetinæ Hydrochloridum; Ipecacuanha; Sinapis; Sodii Chloridum; Zinci Sulphas.

Emmenagogues.—Substances which are used to induce the onset of the menstrual flow.

Drastic Purgatives.—Aloe; Jalapa; Oleum Ricini.

Irritants.—Apiol; Oleum Petroselinii; Oleum Pulegii; Oleum Rutæ; Oleum Sabinæ; Potassii Permanganas; Sabina.

Stimulants of uterine muscle.—Caulophyllum; Ergota; Gossypii Cortex; Quinina.
Oestrinum; Pituitarium (Anterior Sex Hormone).

Emollients.—Substances which protect the skin from irritation and soften the tissues.

Adeps; Adeps Lanæ; Cera Alba; Cera Flava; Cetaceum; Glycerinum; Oleum Amygdalæ; Oleum Arachis; Oleum Coccois; Oleum Gossypii; Oleum Olivæ; Oleum Sesami; Paraffinum Liquidum; Paraffinum Molle.

Expectorants.—Substances which increase or assist bronchial secretion.

Acidum Citricum; Ammonii Acetas; Ammonii Benzoas; Ammonii Carbonas; Ammonii Chloridum; Ammonii Citras; Anisum; Antimonii et Potassii Tartras; Apomorphinæ Hydrochloridum; Balsamum Tolutanum; Benzoinum; Cocillana; Codeina; Glycyrrhiza; Ipecacuanha; Marrubium; Scilla; Senega; Sodii Acetas; Sodii Benzoas; Terebenum; Terpini Hydras; Urtica.

Hæmatinics.—Substances which, in anæmia, increase the quantity or hæmoglobin content of red blood corpuscles.

In macrocytic anæmias.—Extractum Hepatis Liquidum; Extractum Hepatis Siccum; Ventriculus Desiccatus.

Pharmacological Index—*Continued.*

In microcytic anæmias.—Arseni Trioxidum; Cupri Sulphas; Ferri Cacodylas; Ferri Carbonas Saccharatus; Ferri et Ammonii Citro-arsenis; Ferri et Mangani Citras; Ferri et Quininæ Citras; Ferri Iodidum; Ferri Phosphas Saccharatus; Ferri Quininæ et Strychninæ Citras; Ferri Sulphas; Ferrum Redactum; Hæmoglobinum; Mangani Chloridum; Mangani Glycerophosphas; Mangani Hypophosphis; Mangani Peroxidum; Medulla Rubra; Sodii Cacodylas.

Hæmostatics.—Substances which arrest hæmorrhage.

Internal Hæmorrhage.—Acidum Sulphuricum Aromaticum; Adrenalina; Calcii Chloridum; Calcii Lactas; Catechu; Cotarninæ Chloridum; Cotarninæ Phthalas; Emetina; Ephedrina; Ergota; Ergotoxina; Ergotoxinæ Æthanosulphonas; Ergotoxinæ Phosphas; Extractum Pituitarii Liquidum; Gelatinum; Hydrastina; Hydrastinina; Hydrastis; Plumbi Acetas; Serum Normale; Sodii Citras.

External Hæmorrhage.—Acidum Tannicum; Adrenalina; Alumen; Cotarninæ Chloridum; Cotarninæ Phthalas; Cupri Sulphas; Ferri Perchloridum; Galla; Hamamelidis Cortex; Hamamelis; Hydrastinæ Hydrochloridum; Hydrastis; Kino; Krameria; Liquor Hydrogenii Peroxidum; Oleum Terebinthinæ; Serum Normale.

Hypnotics.—Substances which promote sleep.

Non-analgesic.—Alcohol; Allobarbitonum; Barbitonum; Barbitonum Solubile; Carbromalum; Chloralformamidum; Chloralis Hydras; Methylsulphonal; Phenobarbitonum; Phenobarbitonum Solubile; Sulphonal.

Analgesic.—Butylchloralis Hydras; Codeina; Codeinæ Phosphas; Diamorphinæ Hydrochloridum; Hyoscina Hydrobromidum; Hyoscyaminæ Hydrobromidum; Morphina (and its salts); Opium; Papaveretum; Paraldehydum; Urethanum.

Laxatives.—See Cathartics.

Miotics.—Substances which cause contraction of the pupil and diminution of ocular tension.

Physostigmina; Pilocarpina.

Mydriatics.—Substances which cause dilatation of the pupil, paralysis of the ciliary muscle and temporary loss of accommodation.

Atropina; Atropinæ Sulphas; Belladonna; Cocaina; Cocainæ Hydrochloridum; Duboisinæ Sulphas; Ephedrina; Ephedrinæ Hydrochloridum; Homatropinæ Hydrobromidum; Hyoscina; Hyoscina Hydrobromidum.

Pharmacological Index—Continued.

Oxytocics.—Substances which cause contraction of the uterine muscle and are used to hasten parturition.

Extractum Pituitarii Liquidum; Oleum Ricini; Quinina (and its salts).

Parasiticides.—Substances employed to kill animal or vegetable parasites on the skin or hair.

Acidum Benzoicum; Acidum Salicylicum; Balsamum Peruvianum; Benzenum; Cevadilla; Chlorbutol; Chrysarobinum; Derris; Hydrargyri Iodidum Rubrum; Hydrargyri Perchloridum; Hydrargyrum; Hydrargyrum Ammoniatum; Liquor Formaldehydi; Magenta; Oleum Sassafras; Pix Carbonis; Potassa Sulphurata; Pyrethri Flos; Safrolum; Sodii Sulphis; Staphisagria; Sulphur Sublimatum; Sulphuris Chloridum; Sulphuris Iodidum; Veratrinum.

Purgatives.—See Cathartics.

Rubefacients.—See Counter-irritants.

Sclerosants.—Substances used for their sclerosing effect in varicose veins, hæmorrhoids, hydrocele and varicocele.

Dextrosum; Lithii Salicylas; Phenol; Quinina et Urea Hydrochloridum; Quinina Hydrochloridum (with Urethanum); Sodii Chloridum; Sodii Morrhuas; Sodii Salicylas.

Sedatives.—Substances which depress the action of nerve centres or of the circulatory system.

Gastric.—Acidum Hydrocyanicum Dilutum; Ammonii Bromidum; Aqua Laurocerasi; Bismuthi Carbonas; Bismuthi Citras; Bismuthi et Ammonii Citras; Bismuthi Salicylas; Bismuthi Subnitras; Bismuthi Tannas; Carboni Dioxidum (solution); Cerii Oxalas; Chloralformamidum; Chloralis Hydras; Chlorbutol; Chloroformum; Coca; Cocaina; Morphina; Opium; Papaveretum; Potassii Bicarbonas; Potassii Bromidum; Sodii Bicarbonas; Sodii Bromidum.

Respiratory.—Acidum Hydrobromicum Dilutum; Æther; Æthylmorphinæ Hydrochloridum; Ammonii Bromidum; Amylis Nitris; Bromoformum; Chloralis Hydras; Chloroformum; Codeina; Codeinæ Phosphas; Diamorphinæ Hydrochloridum; Gelsemina; Gelsemium; Grindelia; Morphina (and its salts); Opium; Papaveretum; Potassii Bromidum; Prunus Serotina; Sodii Bromidum; Sodii Nitris; Spiritus Ætheris Nitrosi.

Central nervous system.—Acidum Acetylsalicylicum; Acidum Hydrobromicum Dilutum; Acidum Hydrocyanicum Dilutum; Ammonii Bromidum; Camphoræ Monobromidum; Gelsemina; Gelsemium; Hyoscina Hydrobromidum; Hyoscyaminæ Hydrobromidum; Lithii Bromidum; Morphina (and its salts); Opium; Phenacetinum; Phenazonum; Physostigminæ Sulphas; Potassii Bromidum; Sodii Bromidum. (See also Hypnotics.)

Pharmacological Index—Continued.

Sialogogues.—Substances which increase the secretion of the salivary glands.

Hydrargyrum (and its salts); Ipecacuanha; Lobelia; Pilocarpina; Potassii Iodidum (and other iodides); Physostigmina.

Styptics.—See Hæmostatics.

Sudorifics.—See Diaphoretics.

Tonics.—Substances which assist nutrition and improve the general tone of the system.

Heart.—Adrenalina; Æther; Alcohol; Ammonii Carbonas; Barii Chloridum; Caffeina; Caffeina et Sodii Benzoas; Caffeina et Sodii Salicylas; Camphora; Digitalis Folium; Digitalinum; Digitoxinum; Extractum Pituitarii Liquidum; Liqueur Ammonia Dilutus; Nux Vomica; Quinidina; Quinidinæ Sulphas; Scilla; Strophanthinum; Strophanthus; Strychnina (and its salts).

Nerve.—Acidum Formicum (and formates); Acidum Glycerophosphoricum (and glycerophosphates); Acidum Hypophosphorosum (and hypophosphites); Arseni Trioxidum; Cinchona; Ferri Sulphas; Ignatia; Kola; Nux Vomica; Ovocithinum; Phosphorus; Quinina (and its salts); Strychnina (and its salts).

Stomach.—Acidum Hydrochloricum Dilutum; Acidum Nitricum Dilutum; Acidum Nitro-hydrochloricum Dilutum; Acidum Phosphoricum Dilutum; Acidum Sulphuricum Aromaticum; Acidum Sulphuricum Dilutum; Andrographia; Beberinæ Sulphas; Berberinæ Sulphas; Berberis; Calumba; Canella; Cascarilla; Chiretta; Cinchona; Cinchonidina; Cinchonina; Gentiana; Ignatia; Nux Vomica; Pepsinum; Picrorhiza; Quassia; Quebracha; Quinina; Rheum; Salix; Serpentaria; Taraxacum. (See also Carminatives.)

Vasoconstrictors.—Substances which constrict the blood vessels. Adrenalina; Caffeina (and its salts); Digitalis Folium; Ephedrina (and its salts); Ergota; Extractum Pituitarii Liquidum; Hydrastina; Nux Vomica; Strychnina (and its salts).

Vasodilators.—Substances which dilate the blood vessels. Aconitum; Amylis Nitris; Erythrylis Tetranitras Dilutus; Liqueur Glycerylis Trinitratis; Pilocarpina; Sodii Nitris; Sodii Thiocyanas; Sparteinæ Sulphas; Yohimbina.

Vermicides, Vermifuges.—See Anthelmintics.

Vesicants.—See Counter-irritants.

Pharmacological Index—Continued.SUBSTANCES USED FOR THEIR SPECIFIC EFFECT IN
CERTAIN DISEASES

- Beri-Beri*.—Cerevisiæ Fermentum; Vitamin B concentrates.
- Bilharziasis*.—Antimonii et Potassii Tartras; Antimonii et Sodii Tartras.
- Botulism*.—Serum Antibotulinum.
- Cancer*.—Radium.
- Cerebrospinal Meningitis*.—Serum Antimeningococcicum.
- Diabetis Mellitus*.—Insulinum.
- Diphtheria*.—(Treatment), Antitoxinum Diphthericum.
(Prophylaxis), Toxinum Diphthericum Detoxicatum.
- Dysentery*.—(Amœbic), Acetarsol; Emetina; Emetinæ et Bismuthi Iodidum; Emetinæ Hydrochloridum; Holarrhena; Kurchi Bismuthi Iodidum.
(Bacillary), Serum Antidysentericum.
- Gas Gangrene*.—Antitoxinum Welchicum.
- Leprosy*.—Oleum Chaulmoogræ; Oleum Hydnocarpi; Oleum Hydnocarpi Æthylicum; Sodii Chaulmoogras.
- Malaria*.—Cinchona; Quinetum; Quinidina; Quinidinæ Sulphas; Quinina (and its salts); Totaquina.
- Plague*.—Serum Antipestis.
- Rickets*.—Liquor Ergosterolis Irradiati; Vitamin D concentrates.
- Scarlet Fever*.—(Treatment), Antitoxinum Scarlatinum.
(Prophylaxis), Toxinum Scarlatinum.
- Scurvy*.—Succus Aurantii; Succus Limonis; Vitamin C concentrates.
- Small Pox*.—Vaccinum Vacciniæ.
- Snake Bite*.—Serum Antivenenosum.
- Syphilis*.—Acetarsol; Arsphenamina; Arsphenamina Argentica; Bismuthi et Sodii Tartras; Bismuthi Salicylas; Bismuthi Subchloridum; Bismuthum Præcipitatum; Hydrargyri Iodidum Flavum; Hydrargyri Perchloridum; Hydrargyri Salicylas; Hydrargyri Subchloridum; Hydrargyrum; Neoarsphenamina; Potassii Iodidum; Sulpharsphenamina; Tryparsonum.
- Tetanus*.—Antitoxinum Tetanicum.
- Trypanosomiasis*.—Acetarsol; Methylthioninæ Chloridum; Sodii Aminarsonas; Tryparsonum.
- Tuberculosis*.—Auri et Sodii Thiosulphas; Tuberculinum Pristinum; Vaccinum Tuberculinum.
- Typhoid Fever*.—(Prophylaxis), Vaccinum Typho-paratyphosum.

APPENDIX XIV

Substances with Proprietary Trade-Names

The names in the following list are the proprietary names of compounds and preparations described in the British Pharmaceutical Codex and of other proprietary products which may be required in dispensing practice. The information given for each product has been taken from literature issued by the respective makers or agents and includes, in general, an indication of the composition, the therapeutic use and the usual dose. In those cases where the activity of a product is due to the presence of one or more substances described in the British Pharmaceutical Codex, or where it is due to an ingredient stated to have an action similar to that of a substance described in the book, the therapeutic use and dose have not been given, since adequate information on these points is provided in the respective monographs. In order to indicate sources from which further information concerning the products can be obtained, the names of firms or companies associated with their production or distribution are also included.

Considerations of space have made it impossible to include more than a small fraction of the branded products which are available for use in medicine and pharmacy, and the inclusion of a substance in the list does not imply any recommendation or guarantee of purity. In making the selection, preference has been given to proprietary names of substances described in the British Pharmaceutical Codex, and to products depending for their action on substances which are not described in the book. With few exceptions, compounded elixirs, emulsions, mixtures, or ointments containing more or less well-known ingredients have not been included.

When a trade-name is stated to be a brand of a substance described in a monograph in the British Pharmaceutical Codex, it is not intended to imply that the standard laid down in the monograph is also applicable to the branded product, and it is important to note that the majority of names included in the list are registered trade-marks and that when a substance is ordered under its trade-mark description, it is an actionable infringement to supply a product of another maker.

Abrodil.—20 per cent. solution of sodium monoiodomethanesulphonate which contains 52 per cent. of iodine. It is used for retrograde pyelography. (*Bayer Products, London.*)

Acécoline.—Brand of Acetylcholinæ Hydrochloridum. (*Lamatte, Paris; Anglo-French Drug Co., London*)

Acedicone.—Acetyldihydrocodeinone, a white powder soluble in water. It is administered orally or by subcutaneous injection as a sedative, in doses of 0.0025 to 0.01 gramme ($\frac{1}{20}$ to $\frac{1}{10}$ grain). (*Boehringer, Ingelheim; C. Zimmerman, London.*)

Acetylarsan.—23.6 per cent. solution of diethylamine hydroxyacetylaminophenylarsonate containing the equivalent of 0.05 gramme of arsenic per millilitre. It is used for the same purposes as Sodii Aminarsonas. (*May and Baker, London.*)

Substances with Proprietary Trade-Names—Continued.

- Acitophosan.**—Combination of calcium phenylcinchonate and calcium acetylsalicylate. It is administered in the form of powder or tablets, in doses of 8 to 16 grains, in the treatment of painful rheumatic affections and of influenza. (*Richter, London.*)
- Adalin.**—Brand of Carbromalum. (*Bayer Products, London.*)
- Adexolin.**—Vitamin concentrate containing in each millilitre 40,000 units of vitamin A and 2000 international units of vitamin D. It is available in the form of liquid, or in capsules each equivalent to 0.5 millilitre of the liquid, or as a compound emulsion with calcium. (*Glaxo Laboratories, London.*)
- Advita.**—Preparation containing vitamins A and D, with a blue value of 1250 and containing 1000 units of vitamin D per gramme. It is administered in the form of capsules containing 2 minims. (*Trufood, London.*)
- Æthocaine.**—Brand of Procainæ Hydrochloridum. (*Nederlandsche Cocainefabriek, Amsterdam; Greef, London.*)
- Afenil.**—Double compound of calcium chloride and urea supplied in 10 per cent. solution for intravenous calcium treatment. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Agomensin.**—Water-soluble ovarian hormone, administered in the treatment of functional amenorrhœa. (*Ciba, London.*)
- Agonol.**—Benzoic ester of santalol, administered in capsules in place of oil of sandal wood. (*Cognet, Paris; Roberts, London.*)
- Agotan.**—Brand of Cinchophenum. (*Howards, Ilford.*)
- Agurin.**—Brand of Theobromina et Sodii Acetas. (*Bayer Products, London.*)
- Airol.**—Brand of Bismuthi Oxyiodogallas. (*Hoffman-La Roche, London.*)
- Alasil.**—Combination of calcium acetylsalicylate and Alocol in tablet form. (*Wander, London.*)
- Albargin.**—Combination of gelatose and silver nitrate, containing 15 per cent. of silver, used for the same purposes as Argenti Proteinæ Mite. (*Bayer Products, London.*)
- Albarol.**—Prepared barium sulphate for an opaque meal. (*May and Baker, London.*)
- Alepol.**—The sodium salts of a selected fraction of the lower melting-point fatty acids of hydnocarpus oil. It is administered either subcutaneously or intramuscularly as a 3 per cent. w/v solution in 0.5 per cent. w/v aqueous solution of phenol, in doses of 1 millilitre (15 minims), gradually increased to 5 millilitres (75 minims) or more. (*Burroughs Wellcome, London.*)
- Alepsal.**—Combination of phenobarbitone, $1\frac{1}{2}$ grains, belladonna, $\frac{1}{8}$ grain, and caffeine, $\frac{3}{4}$ grain, in tablet form, administered in the treatment of epilepsy. (*Genevriër, Neuilly; Wilcox Jozeau, London.*)
- Alexipon.**—Brand of Æthylis Salicylas. (*Richter, London.*)
- Alkagen.**—Freshly hydrated magnesium oxide, in the form of tablets or lozenges flavoured with oil of peppermint, for use as an antacid. (*Allen and Hanburys, London.*)
- Allisatin.**—Preparation of gastric and activated charcoal in tablet form, administered in the treatment of intestinal affections. (*Sandoz, London; Brooks and Warburton, London.*)
- Allochrysin.**—Sodium aurothioproponalsulphonate, containing 35 per cent. of gold. It is administered by intramuscular injection in the treatment of tuberculosis, chronic rheumatism and lupus, in weekly doses of 0.05 to 0.2 gramme ($\frac{1}{2}$ to 3 grains). (*Lumière, Lyons; Anglo-French Drug Co., London.*)

Substances with Proprietary Trade-Names—Continued.

- Allonal.**—Allylisopropylbarbituric acid, 0·06 gramme (1 grain), with amidopyrine, 0·1 gramme (1½ grains) in tablet form, administered as a sedative and hypnotic. (*Hoffman-La Roche, London.*)
- Alocol.**—Brand of Aluminii Hydroxidum in colloidal form. (*Wander, London.*)
- Alopon.**—Brand of Papaveretum. (*Allen and Hanburys, London.*)
- Alypin.**—Brand of Amydricainæ Hydrochloridum. (*Bayer Products, London.*)
- Ambrine.**—Variety of hard paraffin containing 5 per cent. of oil of amber for use in the treatment of burns, ulcers, etc. (*Anglo-French Drug Co., London.*)
- Ametox.**—Sterile sodium thiosulphate supplied in ampoules containing the powder or solution. (*May and Baker, London.*)
- Amino-Glaucosan.**—10 per cent. solution of histamine hydrochloride used in the form of eye-drops as a powerful miotic in the treatment of acute glaucoma. (*Walm, Spangenberg; Saccharin Corporation, London.*)
- Amphotropin.**—Hexamine camphorate for administration in doses of 0·3 to 1 gramme (5 to 15 grains) in the treatment of infections of the urinary tract. (*Bayer Products, London.*)
- Amytal.**—isoAmylethylbarbituric acid, a white, crystalline powder having a slightly bitter taste. It is very slightly soluble in water, soluble in alcohol and ether, and melts at about 154°. It is administered as a sedative in doses of 0·02 to 0·045 gramme (⅓ to ⅔ grain), and as a hypnotic in doses of 0·1 to 0·3 gramme (1½ to 5 grains). As a basal hypnotic, before a general anæsthetic, the dose ranges from 0·2 to 0·6 gramme (3 to 10 grains). (*Eli Lilly, London.*)
- Anabolin.**—Preparation containing a physiologically tested extract of liver. It is administered orally in the form of tablets, or by intramuscular injection of a solution, in the treatment of functional hypertension. (*Endocrines, Watford.*)
- Anæsthesin.**—Brand of Benzocaina. (*Bayer Products, London.*)
- Anasarcin.**—Tablets containing scillipicridin and scillitoxin, glycosides from squill, administered in the treatment of cardiac affections. (*Anasarcin Co., New York; Christy, London.*)
- Androstin.**—Physiologically standardised total testicular extract for administration in the treatment of impotence and various neuroses and psychoses of genital origin. The tablets, each representing the active principles of 8 grammes of fresh gland, are administered in doses of 3 to 8 daily. For injection, separate ampoules (A and B) are supplied containing respectively the hydrosoluble fraction from the spermatid gland and the lipo-soluble testicular hormone from the interstitial cells. Ampoules A and B are administered alternately, by intramuscular injection. (*Ciba, London.*)
- Anestile.**—Mixture of methyl and ethyl chlorides for the production of local anæsthesia. (*Bengué, London.*)
- Anotal.**—The ethylurethane of phenylcinchoninic acid in tablet form. It is administered in the treatment of gout and rheumatic diseases. (*Merck, Darmstadt; Napp, London.*)
- Anthrasol.**—An oily fluid for external application as a non-staining substitute for tar. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Antibacsyn.**—An anti-bacterial solution for injection in the treatment of pneumonia and septic infections. (*Antibody Products, Watford.*)
- Antiformin.**—Strongly alkaline solution of sodium hypochlorite containing, approximately, available chlorine, 5·7 per cent., sodium hydroxide, 7·8 per cent., and sodium carbonate, 0·3 per cent. A 15 per cent. dilution dissolves non-acid-fast bacteria very rapidly. It has little action on acid-fast organisms, such as the tubercle bacillus, and is used to isolate these organisms from sputum. (*Kuhn, Berlin.*)

Substances with Proprietary Trade-Names—Continued.

- Antileprol** (Chaulmestrol).—The ethyl esters of the fatty acids of chaulmoogra oil. (*Bayer Products, London.*)
- Antilusin A.**—Specially prepared normal horse serum for or aladnustration in doses of 10 millilitres one to three times daily, in the treatment of gastric, duodenal, and other ulcerations. (*Allen and Hanburys, London.*)
- Antilusin B.**—Specially prepared normal horse serum for local application to suppurating wounds and ulcers. (*Allen and Hanburys, London.*)
- Antoxylin.**—Pituitary (anterior lobe) extract prepared for hypodermic injection, each millilitre being equivalent to 2 grains of desiccated gland. (*Oxo, London.*)
- Antuitrin.**—Pituitary (anterior lobe) extract prepared for hypodermic injection. (*Parke Davis, London.*)
- Antuitrin S.**—Solution of the anterior pituitary-like hormone [see pituitary (anterior lobe) extract]. (*Parke Davis, London.*)
- Aolan.**—Milk protein prepared for intramuscular injection in treatment by non-specific protein therapy. (*Beiersdorf, Welwyn Garden City.*)
- Aphrodine.**—Brand of Yohimbina. (*C. Zimmermann, London.*)
- Apicosan.**—Sterile solution of bee-sting toxin in physiological solution of sodium chloride. It is supplied in three strengths and is administered intramuscularly as a counter-irritant in the treatment of rheumatism, neuralgia, neuritis, and similar affections. (*Wolff, Bielsfeld.*)
- Aplexil.**—Polyvalent anti-influenzal vaccine. (*May and Baker, London.*)
- Apothesine.**—Hydrochloride of γ -diethylaminopropyl cinnamate. It is supplied in solution with chloretone, or in tablet form, for use as a local anæsthetic. (*Parke Davis, London.*)
- Apyrogen.**—Brand of Aqua Sterilisata for intravenous use. (*Allen and Hanburys, London.*)
- Arcanol.**—Combination of 0.5 gramme ($7\frac{1}{2}$ grains) each of acetylsalicylic acid and Novatophan in tablet form. It is used for the same purposes as Cinchophenum. (*Schering, London.*)
- Arcolax.**—Brand of Psyllium. (*Roberts, London.*)
- Arecan.**—Solution of procaine hydrochloride with adrenaline. It is supplied in various strengths for use as a local anæsthetic. (*Evans Sons Lescher and Webb, Liverpool.*)
- Arguin.**—Brand of Argenti Proteinæ. (*Allen and Hanburys, London.*)
- Argyn.**—Brand of Argenti Proteinæ Mite. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Argyrol.**—Brand of Argenti Proteinæ Mite. (*Barnes, Philadelphia; Fassett and Johnson, London.*)
- Arhéol.**—Capsules containing 0.2 gramme of santalol. (*Astier, Paris; Wilcox Jozeau, London.*)
- Aristochin.**—Carbonic ester of quinine, occurring as a tasteless, insoluble powder. It is used for the same purposes as quinine. (*Bayer Products, London.*)
- Aristol.**—Brand of Thymolis Iodidum. (*Bayer Products, London.*)
- Arrhenal.**—Brand of Disodii Methyларsonas. (*Adrian, Paris.*)
- Arsacetin.**—Sodium acetylarsanilate. It is used in the treatment of malaria, syphilis and trypanosomiasis. (*Bayer Products, London.*)
- Arsamin.**—Brand of Sodii Aminarsonas. (*Martindale, London.*)
- Arseno-argenticum.**—Brand of Arsphenamina Argentica. (*May and Baker, London.*)

Substances with Proprietary Trade-Names—Continued.

- Arsenobenzol-Billon.**—Brand of Arsphenamina. (*Société Parisienne d'Expansion Chimique, Paris.*)
- Arsenobillon.**—Brand of Arsphenamina. (*May and Baker, London.*)
- Arthigon.**—Polyvalent gonococcal vaccine containing a specific and a non-specific stimulant. (*Schering, London.*)
- Arthrytin.**—Ammonium *o*-iodoxybenzoate, a white, crystalline powder. It is administered by the mouth or by intravenous injection, in doses of 0.5 to 1 gramme ($7\frac{1}{2}$ to 15 grains), in the treatment of arthritis and neuritis. (*May and Baker, London.*)
- Arvitin.**—Brand of Argenti Proteinase Mite. (*Johnson and Sons, London.*)
- Asciatine.**—Amidopyrinebutylchloral hydrate in tablet form for oral administration as an analgesic and hypnotic. (*May and Baker, London.*)
- Asparol.**—Combination of calcium acetylsalicylate and caffeine in tablet form, each tablet containing the equivalent of 0.4 gramme (6 grains) of acetylsalicylic acid and 0.05 gramme ($\frac{1}{2}$ grain) of caffeine. (*Stroschein, Berlin; Christy, London.*)
- Aspirgran.**—Brand of Acidum Acetylsalicylicum in granular form. (*Monsanto, London.*)
- Aspriodine.**—Acetyliodosalicylic acid. It is administered in the form of tablets or cachets in doses of 0.3 gramme (5 grains) per day in the treatment of rheumatic conditions. (*Martindale, London.*)
- Aspro.**—Brand of Acidum Acetylsalicylicum in tablet form. (*Gollin, Slough.*)
- Atebrin.**—A synthetic acridine derivative. It is administered in tablet form in the treatment of malaria. (*Bayer Products, London.*)
- Atocin.**—Brand of Cinchophenum. (*Cavendish Chemical Co., London.*)
- Atophan.**—Brand of Cinchophenum. (*Schering, London.*)
- Atophanyl.**—Cinchophen-sodium with sodium salicylate. It is administered by intramuscular or intravenous injection. (*Schering, London.*)
- Atoquinol.**—Allyl phenylquinolincarboxylate in tablet form. It is used for the same purposes as Cinchophenum. (*Ciba, London.*)
- Atoxyl.**—Brand of Sodii Aminarsonas. (*Boehden, Berlin.*)
- Auremetine.**—Compound of auramine and emetine periodide containing 28 per cent. of emetine and 16 per cent. of auramine. It is administered in the treatment of amœbic dysentery in doses of 1 grain four times daily. (*Martindale, London.*)
- Aurobin.**—Brand of Auri et Sodii Thiosulphas. (*Richter, London.*)
- Avantine.**—Brand of Alcohol Isopropylicum. (*Howards, Ilford.*)
- Avenyl.**—2-Myristoxymercuri-3-hydroxybenzaldehyde. It is used in the treatment of leprosy complicated with syphilis, and is administered by subcutaneous injection as a 0.25 per cent. w/v solution in hydnocarpus oil, or as a 0.5 per cent. w/v solution in ethyl esters of hydnocarpus oil, in doses of 1 millilitre (15 minims), gradually increased. (*Burroughs Wellcome, London.*)
- Avertin.**—Solution of tribromomethyl alcohol in amylene hydrate for use as a basal hypnotic. It is administered by the rectum, in doses of 0.1 to 0.15 gramme per kilogram body weight, with a maximum dose of 10 grammes, as a 2.5 to 3 per cent. aqueous dilution of the solution. The diluted liquid should not be acid to congo-red. (*Bayer Products, London.*)
- Avoleum.**—Concentrated preparation of vitamin A obtained from mammalian liver. It is supplied in capsules containing 3 minims. (*British Drug Houses, London.*)
- B.A.C. Powder.**—Equal parts of dried *Bacillus Acidophilus* and *B. Bulgaricus* in a living state. It is administered with milk in the treatment of various intestinal affections. (*Evans Sons Lescher and Webb, Liverpool.*)

Substances with Proprietary Trade-Names—Continued.

- Bacté-phages.**—Therapeutic bacteriophages in various combinations in ampoules for oral use, or local application. The strains of bacteria employed include those adapted to *Bacillus coli*, staphylococci, streptococci, pneumobacilli and *B. dysenteriae*. (*Robert et Carrière, Paris; Anglo-French Drug Co., London.*)
- Barkite.**—Brand of Methylcyclohexanylis Oxalas. (*Howards, Ilford.*)
- Barolac.**—A 30 per cent. suspension of barium sulphate for use as an opaque meal. (*Burroughs Wellcome, London.*)
- B.C.G. Vaccine.**—A vaccine prepared from an attenuated strain of bovine tubercle bacilli (Bacille Calmette-Guérin) successively subcultured until no longer capable of producing progressive tuberculosis in animals. It is administered orally or by injection in the prophylaxis of infants against tuberculosis. (*Pasteur Institute, Paris.*)
- Belladrenal.**—Combination of Bellafoline, $\frac{1}{100}$ grain, and phenobarbitone, $\frac{1}{2}$ grain, in tablet form. It is administered as a sedative in the treatment of migraine and epilepsy. (*Sandoz, London; Brooks and Warburton, London.*)
- Belladonna-Neutralon.**—Preparation of Neutralon with 0.6 per cent. of extract of belladonna. (*Schering, London.*)
- Bellafoline.**—Total alkaloids of belladonna leaf prepared for oral or hypodermic administration. (*Sandoz, London; Brooks and Warburton, London.*)
- Bemax.**—Preparation of the seed-germ of certain cereals containing vitamins A, B₁, B₂ and E. It is administered in the treatment of constipation and vitamin B deficiency. (*Vitamins, London.*)
- Beta-Borocaine.**—Benzamine borate. It is used in 0.25 to 0.5 per cent. solution for the production of surface anaesthesia in ear, nose and throat work. (*British Drug Houses, London.*)
- Beta-Eucaine Hydrochloride.**—Brand of Benzamina Hydrochloridum. (*Schering, London.*)
- Beta-Eucaine Lactate.**—Brand of Benzamina Lactas. (*Schering, London.*)
- B.F.I.**—Bismuth-formic-iodide, supplied in the form of a compound dusting powder or ointment for use as an antiseptic wound dressing. (*Sharp and Dohme, London.*)
- Bicreol.**—Suspension of precipitated bismuth in an oily basis, containing 0.15 gramme of metallic bismuth per millilitre. (*Burroughs Wellcome, London.*)
- Bilein.**—Brand of Sodii Tauroglycocholas. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Bi-liposol.**—Bismuth camphocarbonate in olive oil solution, containing the equivalent of 0.04 gramme of bismuth per millilitre, for intramuscular injection in the treatment of syphilis. (*Laboratoire Français de Chimiothérapie, Paris; Modern Pharmacals, London.*)
- Biocholine.**—Solution of choline hydrochloride, containing 0.02 gramme per millilitre, for administration by subcutaneous injection in the treatment of tuberculosis and blackwater fever. (*Robert et Carrière, Paris; Anglo-French Drug Co., London.*)
- Biomucine.**—Preparation of mucin from gastric mucus. It is supplied in cachets for administration in the treatment of hyperchlorhydria and peptic ulcer. (*Robert et Carrière, Paris; Anglo-French Drug Co., London.*)
- Bisantal.**—Suspension of bismuth salicylate in oil. (*Muy and Baker, London.*)
- Bisglucol.**—Suspension of precipitated bismuth, 20 per cent., in isotonic dextrose solution. (*May and Baker, London.*)

Substances with Proprietary Trade-Names—Continued.

- Bismarsen.**—Soluble compound of sulpharsphenamine with bismuth. It is administered intramuscularly in doses of 0·1 to 0·2 gramme in the treatment of syphilis. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Bismo-cymol.**—A basic bismuth salt of camphor-3-carboxylic acid containing 37 to 40 per cent. of bismuth. It is supplied in solution in olive oil containing the equivalent of 0·05 gramme of bismuth per millilitre. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Bismosalvan.**—10 per cent. w/v sterile suspension of quinine iodobismuthate in olive oil, for intragluteal injection in the treatment of syphilis. (*Richter, London.*)
- Bismosalvan Soluble.**—Solution of quinine iodobismuthate for intragluteal injection in the treatment of syphilis. Each millilitre contains the equivalent of 0·0225 gramme (about $\frac{1}{4}$ grain) of metallic bismuth. (*Richter, London.*)
- Bismosan.**—10 per cent. suspension of bismuth salicylate in oil. (*Roberts, London.*)
- Bismosol.**—Aqueous solution of sodium potassium bismuthotartrate, piperazine and dextrose. (*Poulenc, Paris.*)
- Bismostab.**—Brand of Injectio Bismuthi. (*Boots, Nottingham.*)
- Bismurung.**—Preparation of colloidal bismuth oxychloride used as an ointment, or in other forms, in the treatment of skin affections. (*Blythswood Chemical Co., Glasgow.*)
- Bismutol.**—Oily suspension of sodium potassium bismuthotartrate. It is administered by intramuscular injection in the treatment of syphilis and yaws. (*Martindale, London.*)
- Bisoxyl.**—Sterile suspension of finely divided bismuth oxychloride, containing 0·1 gramme per millilitre. (*British Drug Houses, London.*)
- Bistovol.**—Oily suspension of the basic bismuth salt of Stovarsol. It is administered by intramuscular injection in the treatment of syphilis. (*May and Baker, London.*)
- Bivatol.**—Basic bismuth α -carboxethyl- β -methylnoncate. A lipo-soluble bismuth compound supplied in 2 millilitre ampoules containing the equivalent of 0·07 gramme of bismuth. It is administered by intramuscular injection in the treatment of syphilis, yaws and lupus. (*Laboratoire Français de Chimiothérapie, Paris; Anglo-French Drug Co., London.*)
- Borocaine.**—Procaine borate. It is used for the same purposes as Procainæ Hydrochloridum. (*British Drug Houses, London.*)
- Brominol, Heavy.**—Brominated vegetable oil containing 33 per cent. of bromine. It is used for X-ray visualisation. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Brominol, Light.**—Brominated preparation of the ethyl esters of the fatty acids of olive oil. It is used for X-ray visualisation. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Bromipin.**—Bromine addition product of sesame oil containing 10 or 33 per cent. of bromine. It is used as a substitute for inorganic bromides. (*Merck, Darmstadt; Napp, London.*)
- Bromoline.**—Flavoured brominated oil containing 10 per cent. of bromine. It is administered internally in place of inorganic bromides. (*Oppenheimer, London.*)
- Bromural.**— α -Monobromisovalerylcarbamide. It is administered as a sedative and hypnotic in doses of 0·3 to 1 gramme (5 to 15 grains). (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Brosedan.**—A preparation of sodium bromide, 25 per cent., and yeast extract. It is administered dissolved in hot water as a sedative bouillon. (*Tammler, Berlin; Coates and Cooper, London.*)

Substances with Proprietary Trade-Names—Continued.

- Butesin.**—*n*-Butyl *p*-aminobenzoate. It occurs as a white, crystalline powder soluble in fixed oils, and is used in the form of a dusting powder or ointment as a local anaesthetic for painful wounds and ulcers. The picrate is employed as an antiseptic local anaesthetic in the form of an ointment or dusting powder. (*Abbott, Chicago; Pharmaceutical Products, London*.)
- Butolan.**—Carbaminic acid ester of *p*-hydroxydiphenylmethane. It is administered in tablet form as an anthelmintic, particularly in the treatment of oxyuriasis. (*Bayer Products, London*.)
- Butyn.**—Sulphate of *p*-aminobenzoyl- γ -di-*n*-butylaminopropanol. It is used in 2 per cent. solution as a local anaesthetic, particularly for surface anaesthesia. (*Abbott, Chicago; Pharmaceutical Products, London*.)
- Cabiven.**—Sterile 66 per cent. solution of dextrose for the injection treatment of varicose veins. (*Thilo, Mainz; Coates and Cooper, London*.)
- Cafaspin.**—Combination of acetylsalicylic acid and caffeine in tablet form. (*Bayer Products, London*.)
- Caffanilide.**—Preparation of acetanilide and caffeine administered in doses of 0.2 to 0.6 gramme (3 to 10 grains). (*Duncan Flockhart, Edinburgh*.)
- Cafinal.**—Combination of Luminal ($\frac{3}{4}$ grain) and caffeine ($\frac{3}{4}$ grain) in tablet form. (*Bayer Products, London*.)
- Calcibronat.**—Preparation containing bromine and calcium gluconate. It is administered in granules or in effervescent tablets (*Sandoz, London; Brooks and Warburton, London*.)
- Calcio-Coramine.**—Combination of Coramine and calcium thiocyanate in tablet form. It is used instead of Coramine when an expectorant action is required. (*Ciba, London*.)
- Calciostab.**—Sterile 10 per cent. solution of calcium thiosulphate for injection in the treatment of intoxication arising from the administration of arsenic, bismuth or mercury preparations. (*Boots, Nottingham*.)
- Calcium-Diuretin.**—Combination of calcium salicylate and the calcium derivative of theobromine. It is used in doses of 0.5 to 1 gramme (8 to 15 grains) for the same purposes as Theobromina et Sodii Salicylas. (*Knoll, Ludwigshafen; Pharmaceutical Products, London*.)
- Calcium L.B.**—Calcium lactobionate, $\text{Ca}(\text{C}_{12}\text{H}_{21}\text{O}_{12})_2$. It is supplied in solution in ampoules containing 2 grammes in 5 millilitres, equivalent to 0.1 gramme of calcium, and is administered by intramuscular or subcutaneous injection in the treatment of various forms of calcium deficiency. (*Allen and Hanburys, London*.)
- Calcium-Sandoz.**—Brand of Calcium Gluconas. It is prepared in various forms for the oral, intravenous, or intramuscular administration of calcium. (*Sandoz, London; Brooks and Warburton, London*.)
- Calcosol.**—10 or 20 per cent. solution of calcium chloride and urea for the intravenous administration of calcium. (*Richter, London*.)
- Calsoma.**—An effervescent preparation containing phosphates of calcium, magnesium and sodium for use in the treatment of hyperacidity. (*Abbott, Chicago; Pharmaceutical Products, London*.)
- Camphemyl.**—10 per cent. solution of camphor in a mixture of methylurethane, monoethylurea and distilled water. It is used in doses of 1 to 3 millilitres as a substitute for oily injections of camphor. (*Ciba, London*.)
- Campolon.**—An extract of liver prepared for intramuscular injection, 2 millilitres being equivalent to 500 grammes of fresh liver administered orally. (*Bayer Products, London*.)
- Caprokol.**—Solution of hexyl-resorcinol in olive oil. (*Sharp and Dohme, London; British Drug Houses, London*.)

Substances with Proprietary Trade-Names—Continued.

- Carbitol.**—Brand of diethyleneglycolmonoethylether. (*Carbide and Carbon Chemicals, New York.*)
- Carboserin.**—Brand of Carbo Activatus. (*Bayer Products, London.*)
- Cardiazol.**—Pentamethylenetetrazol, a white, crystalline powder soluble in water. It is used as a cardiac and respiratory stimulant and is administered orally in solution or by subcutaneous injection in doses of $1\frac{1}{2}$ to 3 grains. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Cargentos.**—Brand of Argenti Proteinase Mite. (*Sharp and Dohme, London.*)
- Chinamin.**—Solution containing a neutral salt of quinine, with adrenaline and an extract of hamamelis, for spraying into the nostrils in the prophylaxis and treatment of hay fever. (*Allen and Hanburys, London.*)
- Chineonal.**—Quinine diethylbarbiturate. It is administered as a sedative and antipyretic. (*Merck, Darmstadt; Napp, London.*)
- Chinethan.**—Sterile solution of quinine dihydrochloride and urethane administered by intramuscular injection in the treatment of malaria, pneumonia, influenza and other diseases. (*Richter, London.*)
- Chiniofon.**—Iodoxyhydroxyquinolinesulphonic acid mixed with sodium bicarbonate. It occurs as a yellow powder, soluble in water, and is administered as an antiseptic in the treatment of amœbic dysentery, in doses of 0.25 to 1 gramme (4 to 15 grains) three times a day. It may also be administered by rectal injection of 200 millilitres of a 0.5 to 2.5 per cent. solution. (*Searle, Chicago.*)
- Chinosol.**—Brand of Potassii Hydroxyquinolini Sulphas. (*Chinosolfabrik, Hamburg; C. Zimmermann, London.*)
- Chlorazene.**—Brand of Chloramina. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Chloretone.**—Brand of Chlorbutol. (*Parke Davis, London.*)
- Chlorostab.**—Suspension of bismuth oxychloride in 5 per cent. dextrose solution. It is supplied in two strengths containing respectively the equivalent of 0.16 and 0.20 gramme of metallic bismuth per millilitre. (*Boots, Nottingham.*)
- Chloroxyl.**—Cinchophen hydrochloride. (*Eli Lilly, London.*)
- Chloryl Anæsthetic.**—Brand of Ethylis Chloridum. (*Duncan Flockhart, Edinburgh.*)
- Chlorylen.**—Brand of Trichlorethylum. (*Schering, London.*)
- Choleval.**—A compound of colloidal silver and sodium cholate for use in the treatment of gonorrhœa. (*Merck, Darmstadt; Napp, London.*)
- Chrimol.**—Brand of Paraffinum Liquidum. (*Allen and Hanburys, London.*)
- Cibalbumin.**—Aqueous solution of animal protein administered hypodermically, intravenously, or intramuscularly in doses of 2 to 10 millilitres in treatment by non-specific protein therapy. (*Ciba, London.*)
- Cibalgin.**—Amidopyrine with Dial. It is supplied in the form of tablets or in solution for oral or intravenous administration as a sedative. Each tablet represents 0.22 gramme ($3\frac{1}{2}$ grains) of amidopyrine and 0.03 gramme ($\frac{1}{2}$ grain) of Dial. (*Ciba, London.*)
- Cignolin.**—Dioxyanthranol. It is used in the form of a paint or ointment containing 0.25 to 2 per cent. as a non-staining substitute for chrysarobin in the treatment of various skin diseases. (*Bayer Products, London.*)
- Cincaine.**—*iso*Propylhydrocupreine hydrochloride. It is used as a local anæsthetic. (*Howards, Ilford.*)
- Citobaryum.**—Prepared barium sulphate for use as a barium meal. (*Merck, Darmstadt; Napp, London.*)

Substances with Proprietary Trade-Names—Continued.

- Coagulén-Ciba.**—A hæmostatic derived from normal bovine cells. It is supplied in the form of powder and ampoules; the former is used locally for treating accessible hæmorrhage and the latter for internal hæmorrhage. (*Ciba, London.*)
- Codeonal.**—Combination of codeine diethylbarbiturate, 2 parts, and sodium diethylbarbiturate, 15 parts, in tablet form. It is administered in doses of $2\frac{1}{2}$ to $7\frac{1}{2}$ grains as a sedative and hypnotic. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Colitique.**—Suspension of killed *Bacillus coli* prepared for oral administration or for subcutaneous injection in the treatment of *B. coli* infections. (*Astier, Paris; Wilcox Jozeau, London.*)
- Collargol.**—Colloidal compound of albumen and silver, containing at least 70 per cent. of silver. It is used for the same purposes as Argenti Proteinæ. (*Heyden, Dresden; Braun, London.*)
- Colliron.**—Preparation of colloidal iron (10 per cent.), with a trace of copper, administered in doses of 1 to 4 fluid drachms in the treatment of secondary anæmias and allied conditions. (*Evans Sons Lescher and Webb, Liverpool.*)
- Colonol.**—Brand of Paraffinum Liquidum. (*Kaylene, London.*)
- Compral.**—Combination of amidopyrine and trichlorethylmethane in the form of tablets containing $7\frac{1}{2}$ grains. It is administered as an analgesic and sedative in doses of one or two tablets. (*Bayer Products, London.*)
- Contramine.**—Diethylammonium diethyldithiocarbamate. It is administered intramuscularly in the treatment of gonorrhœa, chronic arthritis and metallic intoxication, in doses of 0.05 to 0.25 gramme ($\frac{1}{2}$ to 4 grains) dissolved in 1 to 2 millilitres (15 to 30 minims) of sterile water. It may also be applied locally in the form of bougies, pessaries, or suppositories (*British Drug Houses, London.*)
- Coramine.**—Pyridine- β -carboxylic acid diethylamide, a yellowish liquid, almost odourless and tasteless, and miscible with water in all proportions. It is used as a cardiac and respiratory stimulant, and is supplied as a 25 per cent. flavoured solution for oral administration in doses of 1 to 2 millilitres (15 to 30 minims). It is also prepared for subcutaneous, intravenous, or intramuscular injection. (*Ciba, London.*)
- Cortigen.**—Brand of Extractum Suprarenalis Corticis. (*Richter, London.*)
- Creosotal.**—Brand of Creosoti Carbonas. (*Heyden, Dresden; Braun, London.*)
- Crinex.**—Ovarian extract, in the form of an alcoholic solution, containing keto-hydroxyoestrin and other principles. It is administered in doses of 12 to 25 minims daily. (*Continental Laboratories, London.*)
- Crisalbine.**—Brand of Auri et Sodii Thiosulphas. (*May and Baker, London.*)
- Cryogenine.**—Phenylsemicarbazide. It is administered as an antipyretic in the form of tablets in doses of 0.2 to 1 gramme (3 to 15 grains). (*Lumière, Lyons; Anglo-French Drug Co., London.*)
- Cuprase.**—Colloidal suspension of copper hydroxide administered by intramuscular injection in the treatment of cancer. (*Ducatte, Paris; Anglo-French Drug Co., London.*)
- Cuprentum.**—Ointment of soluble copper citrate, 5 per cent., used in the treatment of trachoma and of granulations of the eye-lid. (*Allen and Hanburys, London.*)
- Cuprol.**—Copper salt of nucleic acid. It is applied topically as an astringent in the treatment of ulcers and fistulæ, and in solution for ophthalmic diseases. (*Parke Davis, London.*)
- Cycloform.**—Alkyl ester of *p*-aminobenzoic acid. It is supplied in the form of an ointment with zinc oxide and extract of hamamelis for use as an antiseptic and astringent. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Cylotropin.**—Solution containing in 5 millilitres, Urotropin, 30 grains, sodium salicylate, 12 grains, and caffeine sodium salicylate, 3 grains. It is administered by intramuscular or intravenous injection in the treatment of infective diseases of the urinary tract. (*Schering, London.*)
- Cystazol.**—A combination of hexamine and sodium benzoate in tablet form. It is administered in doses of 0.3 to 1 gramme (5 to 15 grains) in the treatment of cystitis and bacterial infections of the urinary tract. (*Allen and Hanburys, London.*)
- Cystopurin.**—Hexamine sodium acetate. It is administered in doses of 1 to 2 grammes (15 to 30 grains) as a diuretic and in the treatment of cystitis. (*Genatosan, Loughborough.*)
- Davitamon.**—Vitamin preparations containing vitamin A or D, or both. Davitamon A is supplied in oily solution containing 15,000 blue units per millilitre; Davitamon D is supplied in oily solution containing 5000 units per millilitre; Davitamon A and D contains these quantities of both vitamins per millilitre. Davitamon tablets contain 500 units of vitamin D, 0.02 gramme of reduced iron and 0.0002 gramme of copper carbonate. (*Organon Laboratories, London.*)
- Decholin.**—Dehydrocholic acid, supplied in the form of tablets containing 0.25 gramme or in ampoules containing 10 millilitres of a 20 per cent. solution of the sodium salt. It is administered orally or intravenously in the treatment of hepatic diseases. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Degalol.**—*m*-Dihydroxycholic acid supplied in the form of tablets containing 0.1 gramme. It is used in the treatment of cholelithiasis. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Dekrysil.**—4 : 6-Dinitro-*o*-cresol. It is supplied in capsules containing 0.05 gramme for administration in doses of 0.0005 to 0.001 gramme per kilogram body weight in the treatment of obesity by metabolic acceleration. (*British Colloids, London.*)
- Dermatol.**—Brand of Bismuthi Subgallas. (*Bayer Products, London.*)
- Dettol.**—Halogen derivative of xyleneol dissolved in a saponified mixture of aromatic oils. It is used as a non-toxic and non-irritant germicide. (*Reckitt and Sons, Hull.*)
- Dextrosol.**—Brand of Dextrosum. (*Corn Products, London.*)
- Diagnosthorine.**—25 per cent. suspension of colloidal thorium oxide. It is administered orally for the X-ray visualisation of the mucous membrane of the oesophagus, stomach, and duodenum. (*May and Baker, London.*)
- Dial.**—Brand of Allobarbitonum. (*Ciba, London.*)
- Dialacetin.**—Combination of Dial, $1\frac{1}{2}$ grains, and allyl-*p*-acetaminophenol, 4 grains, in tablet form. It is used as a sedative in the treatment of dysmenorrhœa and febrile conditions. (*Society of Chemical Industry, Basle; Clayton Amline Co., London.*)
- Diarsenol.**—Brand of Arsphenamina. (*Diarsenol Co., Buffalo.*)
- Di-citurin.**—Mono-potassium diacetylcitrate in tablet form. It is administered in doses of 2 to 6 tablets in the treatment of hypertension. (*Paines and Byrne, London.*)
- Dicodid.**—Dihydrocodeinone, $C_{18}H_{21}NO_3$, a substitute for morphine and codeine. It is administered by the mouth in doses of 0.005 gramme ($\frac{1}{40}$ grain) of the bitartrate as a sedative in the treatment of cough and affections of the respiratory organs. It may also be administered by subcutaneous injection of the hydrochloride in doses of 0.015 gramme ($\frac{1}{4}$ grain) as an analgesic. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Didial.**—Combination of Dial, $1\frac{1}{2}$ grains, and ethylmorphine diallylbarbiturate, $\frac{1}{2}$ grain, in tablet form. It is administered as a powerful hypnotic in the treatment of severe insomnia. (*Ciba, London.*)
- Digalen.**—Preparation of the total glycosides of digitalis supplied in various forms for administration by the mouth or by injection. (*Hoffman-La Roche, London.*)
- Digifoline.**—Preparation of the total glycosides of digitalis supplied in the form of tablets and ampoules, containing in each the equivalent of $1\frac{1}{2}$ grains of powdered digitalis, or in solution containing the same equivalent in 1 millilitre. (*Ciba, London.*)
- Digifortis.**—Fat-free, physiologically standardised tincture of digitalis, 25 per cent. stronger than the pharmacopœial tincture; it is also available in the form of tablets of dried leaf. (*Parke Davis, London.*)
- Diginutin.**—Solution of the total glycosides of digitalis, containing in 1 millilitre the equivalent of 0.1 gramme of powdered digitalis. (*Burroughs Wellcome, London.*)
- Digipuratum.**—Standardised preparation of digitalis for administration by the mouth or by injection. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Digitaline, Nativelle.**—Preparation containing digitalis glycosides, available in the form of granules, ampoules or solutions. It is used for the same purposes as Digitoxinum. (*Nativelle, Paris; Wilcox Jozeau, London.*)
- Digital.**—Fat-free, biologically standardised tincture of digitalis. (*Sharp and Dohme, London.*)
- Digitos.**—Preparation containing the water-soluble active constituents of digitalis leaves. It is administered intramuscularly or intravenously in doses of 0.3 to 4 millilitres (5 to 60 minims). (*Sharp and Dohme, London.*)
- Dilaudid.**—Dihydromorphinone hydrochloride, $C_{17}H_{19}O_3N.HCl$. It is used as a substitute for morphine in doses of 0.0012 to 0.0025 gramme ($\frac{1}{80}$ to $\frac{1}{40}$ grain) by the mouth, or 0.002 gramme ($\frac{1}{50}$ grain) by subcutaneous injection. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Dimol.**—Dimethylmethoxyphenol, with tri- and tetra-methylphenols. It is administered in the form of tablets or syrup as an intestinal antiseptic, and also used externally in various forms as an antiseptic. (*Dimol Laboratories, London; Sangers, London.*)
- Diocaine.**—*p*-Diallyloxyethyl-diphenyldiamidine hydrochloride. It is used in 0.2 to 0.5 per cent. aqueous solution as a local anæsthetic in ophthalmology. (*Ciba, London.*)
- Dionin.**—Brand of Æthylmorphinæ Hydrochloridum. (*Merck, Darmstadt; Napp, London.*)
- Diplosal.**—Salicylsalicylic acid, $C_6H_4OH.COOC_6H_4.COOH$. It occurs as colourless, tasteless crystals, insoluble in water and acids, soluble in alkalis, and is administered in doses of 1 gramme (15 grains) as an anti-rheumatic. (*Boehringer, Mannheim; Mertens, London.*)
- Dismenol.**—Mixture of equal parts of amidopyrine and *p*-sulphamido-benzoic acid in the form of tablets containing 0.15 gramme of each constituent. It is administered in the treatment of dysmenorrhœa. (*Madlener-Gavin, Genf; Roberts, London.*)
- Disulphamin.**—Combination of dimethylamidoantipyrine camphorate, sodium nucleinate and hexaminesulphosalicylic acid. It is used in solution, either internally in doses of 0.5 gramme ($7\frac{1}{2}$ grains), or as a douche or gargle, in the treatment of influenza and other infections. (*Biochemical Laboratories, Locarno; Coates and Cooper, London.*)

Substances with Proprietary Trade-Names—Continued.

- Diuretin.**—Brand of Theobromina et Sodii Salicylas. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Dmelcos.**—Stabilised vaccine prepared from various strains of the Ducrey bacillus for intravenous injection in the treatment of syphilis. (*May and Baker, London.*)
- Dormigene.**—Monobromisovalerylurea. It is administered as a sedative and hypnotic in doses of 5 to 15 grains. (*Allen and Hanburys, London.*)
- Drikold.**—Brand of solid carbon dioxide. (*Imperial Chemical Industries, London.*)
- Duotal.**—Brand of Guaiacolis Carbonas. (*Heyden, Dresden; Braun, London.*)
- E.D.P.**—Surgical dusting powder containing bismuth formic iodide. (*Evans Sons Lescher and Webb, Liverpool.*)
- Edwenil.**—Antibacterial element from normal serum in sterile solution for subcutaneous injection. It is used as a polyvalent antibacterial agent in the treatment of a number of diseases of bacterial origin. (*Spicer, London.*)
- Elbon-Ciba.**—Cinnamoyl-*p*-oxyphenylurea in tablet form. It is administered in the treatment of tuberculosis and anaphylactic diseases. (*Ciba, London.*)
- Elityran.**—Biologically standardised extract of thyroid. It is administered in doses of 0.025 to 0.05 gramme. (*Bayer Products, London.*)
- Empirin.**—Brand of Acidum Acetylsalicylicum. (*Burroughs Wellcome, London.*)
- Enesol.**—Mercury salicylarsonate. It is injected hypodermically in the treatment of syphilis, the usual dose being 0.06 gramme (1 grain) dissolved in 2 millilitres (30 minims) of water. (*Sempa, Paris; Mertens, London.*)
- Enteromucine.**—Preparation of mucin from intestinal mucus. It is administered orally in the treatment of colitis and constipation. (*Robert et Carrière, Paris; Anglo-French Drug Co., London.*)
- Entero-Vioform.**—Tablets containing 0.25 gramme of Vioform for administration in the treatment of chronic amoebiasis and other parasitic intestinal diseases. (*Ciba, London.*)
- Enzymol.**—Extract of gastric glands for external application in the treatment of various pyogenic affections. (*Fairchild Bros. and Foster, New York; Burroughs Wellcome, London.*)
- Ephetonin.**—Brand of synthetically prepared Ephedrina. (*Merck, Darmstadt; Napp, London.*)
- Epinine.**—3:4-Dihydroxyphenylmethylamine. It resembles adrenaline in its action, but is more stable in slightly acid solution. It is used in 1 per cent. solution in the same manner as solution of adrenaline. (*Burroughs Wellcome, London.*)
- Erbolin.**—Brand of Ergota Præparata in the form of capsules each containing the equivalent of 0.0004 gramme ($\frac{1}{2500}$ grain) of the total alkaloids of ergot, calculated as ergotoxine. (*Glaxo Laboratories, London.*)
- Ergamine.**—Brand of synthetically prepared Histamina. (*Burroughs Wellcome, London.*)
- Ergoapiol.**—Capsules containing the active principles of ergot and apiol and used in the treatment of menstrual disorders. (*Martin H. Smith, New York; Christy, London.*)
- Ergodex.**—Liquid extract of ergot containing 0.06 per cent. of the alkaloids of ergot, calculated as ergotoxine. (*British Drug Houses, London.*)
- Ergole.**—A liquid extract of ergot. (*Oppenheimer, London.*)
- Ergothane.**—Sterile solution of ergotoxine ethanesulphonate containing 0.0005 gramme per millilitre. (*Evans Sons Lescher and Webb, Liverpool.*)

Substances with Proprietary Trade-Names—Continued.

- Ernutin.**—Solution containing ergotoxine ethanesulphonate with Ergamine and tyramine. It is administered orally as a 0.033 per cent. solution in doses of 2 to 4 millilitres ($\frac{1}{2}$ to 1 fluid drachm). For hypodermic or intramuscular injection it is administered as a 0.1 per cent. solution in doses of 0.3 to 0.6 millilitre (5 to 10 minims). (*Burroughs Wellcome, London.*)
- Erythgen.**—Brand of Extractum Hepatis Siccum, representing 40 times its weight of fresh liver. It is also prepared in solution for hypodermic administration. (*Carrick, Newark, N. J.; Brooks and Warburton, London*)
- Eschatin.**—Brand of Extractum Suprarenalis Corticis. (*Parke Davis, London.*)
- Essogen** (Lever's Preparation Y).—Preparation containing vitamin A, with a blue value of 2000. It is supplied in capsules containing 2 minims. (*Trufood, London.*)
- Esterol.**—Brand of Benzylis Succinas. (*Stearns, Detroit.*)
- Ethidol.**—Ethyl iodoricinoleate, containing 20 per cent. of iodine. It does not stain the skin, and is applied externally in the treatment of various inflammations. (*Burroughs Wellcome, London.*)
- Eucerin.**—Mixture of Eucerin (Anhydrous) with an equal weight of water. (*Beiersdorf, Welwyn Garden City.*)
- Eucerin (Anhydrous).**—Mixture of 95 parts of a paraffin ointment with 5 parts of oxysterolins from wool fat. (*Beiersdorf, Welwyn Garden City.*)
- Eucodeine.**—Codeine methylbromide. It is administered orally instead of codeine in doses of 0.05 gramme ($\frac{1}{2}$ grain). (*Boehringer Mannheim; Merck, London.*)
- Eucortone.**—Brand of Extractum Suprarenalis Corticis (*Allen and Hanburys, London.*)
- Eucupin.**—Brand of isoAmylhydrocupreinae Hydrochloridum. (*Zimmer, Mannheim; Pharmaceutical Products, London.*)
- Eugallol.**—Pyrogallol monoacetate. It is applied locally, either undiluted or diluted with acetone, in the treatment of psoriasis and other skin diseases. (*Knoll, Ludwigshafen; Pharmaceutical Products, London*)
- Eugastrol.**—Brand of Ventriculus Desiccatus. (*Allen and Hanburys, London.*)
- Eukodal.**—Dihydroxycodone hydrochloride, $C_{18}H_{21}NO_4.HCl$. It occurs as a white, crystalline powder which is soluble in water. It is administered as a substitute for morphine, in doses of 0.005 gramme ($\frac{1}{20}$ grain) by the mouth, or of 0.01 to 0.02 gramme ($\frac{1}{10}$ to $\frac{1}{5}$ grain) by subcutaneous injection. (*Merck, Darmstadt; Napp, London.*)
- Euparatone.**—Biologically standardised solution of the parathyroid hormone. (*Allen and Hanburys, London.*)
- Eupaverin.**—Synthetic alkaloid obtainable as the hydrochloride and as the sulphate. It is used for the same purposes as Papaverina. (*Merck, Darmstadt; Napp, London.*)
- Eupepton.**—Brand of Peptonum, prepared in two forms; No. 1 is for non-specific protein therapy and for the Rideal-Walker test; No. 2 is for general bacteriological purposes. (*Allen and Hanburys, London.*)
- Euphthalmin** (Eucatropine).—Hydrochloride of phenylglycolyl-N-methylvinyl-diacetonalkamine. It is used in 5 to 10 per cent. solution in water as a mydriatic. (*Schering, London.*)
- Euphyllin.**—Theophylline ethylenediamine, containing about 80 per cent. of theophylline. It is used as a diuretic, particularly in the treatment of oedema of cardiac origin or when complicated by arteriosclerosis. It is administered orally, rectally, intravenously, or intramuscularly, and is supplied in the form of tablets containing 0.1 gramme ($\frac{1}{2}$ grains), suppositories containing 0.36 gramme ($5\frac{1}{2}$ grains), or ampoules containing 0.48 gramme ($7\frac{1}{2}$ grains) in 2 millilitres. (*Whiffen, London.*)

Substances with Proprietary Trade-Names—Continued.

- Eupinal.**—Preparation containing iodide of caffeine administered in the treatment of asthma. (*Cuxson Gerrard, Oldbury.*)
- Eupnine Vernade.**—Preparation containing $7\frac{1}{2}$ grains of caffeine iodide in each fluid drachm administered in the treatment of asthma. (*Darrasse, Nanterre; Wilcox Jozeau, London.*)
- Euquinine.**—Brand of Quininæ et Æthylis Carbonas. (*Zimmer, Mannheim.*)
- Euresol.**—Brand of Resorcinolis Monoacetat. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Euresol pro Capillis.**—Perfumed form of Euresol for use in hair preparations. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Eusolvan.**—Brand of Æthylis Lactas. (*Schering, London.*)
- Euvalerol.**—Odourless preparation of valerian supplied either plain or with the addition of phenobarbitone (2 grains per fluid ounce) or of ammonium and strontium bromides. (*Allen and Hanburys, London.*)
- Evipan.**—N-methyl-C-C-cyclohexenylmethylmalonylurea in tablet form. It is administered in doses of 0.25 to 0.5 gramme (4 to 8 grains) or more, in the treatment of insomnia. (*Bayer Products, London.*)
- Evipan Sodium.**—Sodium derivative of Evipan. It is used for the immediate production of anæsthesia of short duration. It is administered by intravenous injection as a freshly prepared 10 per cent. aqueous solution in doses of 7 to 10 millilitres. (*Bayer Products, London.*)
- Exhepa.**—Brand of Extractum Hepatis Siccum. (*Bencard, London; Woolley, Manchester.*)
- Extomak.**—Brand of Ventriculus Desiccatus. (*Benger, Manchester.*)
- Fæxalin.**—Preparation of dried beer yeast for internal administration in the treatment of skin affections. (*Temmler, Berlin; Coates and Cooper, London.*)
- Felamine.**—Hexamine with cholic acid in tablet form, administered in the treatment of hepatic and allied diseases. (*Sandoz, London; Brooks and Warburton, London.*)
- Felsol.**—Powders containing phenazone, iodopyrine, caffeine and other ingredients for use in the treatment of asthma. (*British Felsol, London.*)
- Femergen.**—Brand of Ergotaminæ Tartras. (*Sandoz, London; Brooks and Warburton, London.*)
- Ferarin.**—Solution of green iron and ammonium citrate with the addition of a soluble form of arsenic. It is administered by intramuscular injection for the same purposes as Injectio Ferri et Arseni. (*Squire, London.*)
- Ferronyl.**—Tablets containing 0.05 gramme of ferrous chloride, used in the treatment of anæmia. (*Norgine, Prague; Napp, London.*)
- Ferrophytin.**—Neutral iron salt of inositol hexaphosphoric acid, containing 7.5 per cent. of iron and 6 per cent. of phosphorus. It is administered in the form of pills containing the equivalent of $\frac{1}{2}$ grain of iron in the treatment of anæmia. (*Ciba, London.*)
- Fibrolysin.**—Solution of thiosinamine and sodium salicylate. (*Merck, Darmstadt; Napp, London.*)
- Filivex.**—Liquid extract of fish livers, each fluid ounce being equivalent to 4 ounces of fresh mammalian liver. It is also available in the form of powder. (*Glaxo Laboratories, London.*)
- Filmarone Oil.**—10 per cent. solution of filmarone in a neutral vegetable oil, for use as a vermifuge. (*Boehringer, Mannheim; Mertens, London.*)
- Fortossan.**—Mixture of Phytin and lactose in powder form. (*Ciba, London.*)

Substances with Proprietary Trade-Names—Continued.

- Fotamilko.**—Barium sulphate, mixed with dried milk and flavoured with lemon, for administration as a fluid barium meal. Fotamealo is a cocoa-flavoured barium meal containing tragacanth as suspending agent. Fotonemal is a slightly flavoured barium sulphate powder for administration in water or other vehicle. (*Evans Sons Lescher and Webb, Liverpool.*)
- Gardan.**—Combination of Pyramidon and Novalgin in tablet form. It is administered in doses of 0.3 to 0.6 gramme (5 to 10 grains). (*Bayer Products, London.*)
- Gardenal.**—Brand of Phenobarbitonum. (*May and Baker, London.*)
- Gardenal Sodium.**—Brand of Phenobarbitonum Solubile. (*May and Baker, London.*)
- Gaster Siccata.**—Brand of Ventriculus Desiccatus. (*British Drug Houses, London.*)
- Gastrezo.**—Brand of Ventriculus Desiccatus. (*Evans Sons Lescher and Webb, Liverpool.*)
- Gastroic.**—Brand of Ventriculus Desiccatus. (*Bencard, London; Woolley, Manchester.*)
- Genasprin.**—Brand of Acidum Acetylsalicylicum in tablet form. (*Genatosan, Loughborough.*)
- Genoscopolamine.**—Nitrogen oxide of scopolamine. It has a marked action on the central nervous system and is employed in the treatment of Parkinsonism. It is supplied in granules, ampoules or in solution and is administered in doses of 0.0005 gramme ($\frac{1}{20}$ grain) two or three times daily. (*Laboratoires Amido, Lille; Wilcox Jozeau, London.*)
- Germanin** (Bayer 205).—Complex organic urea administered in the treatment of trypanosomiasis as a 10 per cent. aqueous solution in doses of up to 10 millilitres by subcutaneous or intravenous injection. (*Bayer Products, London.*)
- Glanduantin.**—Preparation containing the anterior pituitary sex hormone. (*Richter, London.*)
- Glandubolin.**—Brand of ketohydroxyoestrin (see Oestrinum). (*Richter, London.*)
- Glanduitrin.**—Brand of Extractum Pituitarii Liquidum. (*Richter, London.*)
- Glanduovin.**—Extract of the whole ovarian substance. (*Richter, London.*)
- Glaucosan** (Dextro-Glaucosan).—Solution containing 0.2 per cent. of synthetic *d*-adrenaline and 1 per cent. of methylaninoacetocatechol (adrenalone). It is administered by sub-conjunctival injection in the treatment of glaucoma. (*Wälm, Spangenberg; Saccharin Corporation, London.*)
- Glauramine.**—Concentrated solution of auramine in glycerin and alcohol. (*British Drug Houses, London.*)
- Globenil.**—Polyvalent antibody experimentally administered by injection in the treatment of inoperable malignant disease. (*Spicer, London.*)
- G. L. Preparation-A.**—Vitamin A concentrate, free from vitamin D, containing 240,000 units of vitamin A per millilitre. It is also available in capsules containing 3 minims. (*Glaxo Laboratories, London.*)
- Glukhorment.**—Preparation of the pancreas with a guanidine derivative. It is used as a substitute for insulin in the treatment of certain mild cases of diabetes. (*Horment, Berlin.*)
- Gomenol.**—Distilled essence of *Melaleuca Viridiflora* having antiseptic properties. It is used internally and externally in various forms as an antiseptic. (*Laboratoire des Produits du Gomenol, Paris; Coates and Cooper, London.*)
- Gorun.**—Combination of cinchophen, hexamine and glycooll supplied in the form of solution in ampoules for injection, or of cachets for oral administration, in the treatment of rheumatism and sciatica. (*Jacobson, Charlottenburg; Pharmaceutical Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Guipsine.**—Preparation containing the constituents of mistletoe and administered in the form of pills in the treatment of arteriosclerosis. (*Leprince, Paris; Bengué, London.*)
- Gynœstryl.**—Brand of ketohydroxyoestrin (see Oestrinum). It is supplied in solution containing 1000 units per millilitre for oral administration or in ampoules for injection. (*Laboratoire Français de Chimiothérapie, Paris; Anglo-French Drug Co., London.*)
- Halarsol.**—3-Amino-4-hydroxyphenyldichlorarsine hydrochloride. It is prepared in 2.5 per cent. solution for intravenous injection in the treatment of yaws. (*May and Baker, London.*)
- Halibol.**—Brand of Oleum Hippoglossi with added vitamin D, containing 600 units of vitamin A (blue value) and 10,000 units of vitamin D per gramme. (*Allen and Hanburys, London.*)
- Haliverol.**—Brand of Oleum Hippoglossi adjusted to contain a vitamin A potency of 60 times that of cod-liver oil and a vitamin D potency of 250 times that of cod-liver oil. (*Parke Davis, London.*)
- Hebaral Sodium.**—Sodium *n*-hexylethylbarbiturate administered in capsules as a sedative and hypnotic in doses of 3 grains. (*Parke Davis, London.*)
- Hectargyre.**—Combination of Hectine with mercury. (*Mouneyrat, Villeneuve-la-Garenne; Anglo-French Drug Co., London.*)
- Hectine.**—Sodium benzosulpho-*p*-aminophenylarsonate, administered by intramuscular injection or by the mouth in the treatment of syphilis. (*Mouneyrat, Villeneuve-la-Garenne; Anglo-French Drug Co., London.*)
- Hegonon.**—Organic compound of silver and albumose containing 7 per cent. of silver. It is used for the same purposes as Argenti Proteinæ. (*Schering, London.*)
- Helmitol.**—Brand of Formamol. (*Bayer Products, London.*)
- Hemoplastin.**—A serum containing prothrombin and thrombokinase derived chiefly from the blood of horses and cattle. It is administered by subcutaneous or intramuscular injection or orally for the control of hæmorrhage. (*Parke Davis, London.*)
- Hemoprotein.**—A 10 per cent. solution of a protein fraction, obtained from blood fibrin by digestion with pepsin and fractional precipitation, and used for non-specific protein therapy. (*Parke Davis, London.*)
- Hemostyl.**—Fresh hæmopoietic horse serum. It is administered by the mouth in the treatment of anæmias and hæmorrhages. (*Institut de Sérothérapie Hémopoïétique, Paris; Bengué, London.*)
- Hemypnone.**—Preparation of diamorphine diallylbarbiturate and chlorbutol, supplied in the form of tablets or suppositories for use in the induction of "twilight sleep." The tablets contain the equivalent of $\frac{1}{15}$ grain of Dial, with $\frac{1}{2}$ grain of ethylmorphine and $7\frac{1}{2}$ grains of chlorbutol; the suppositories contain the equivalent of $\frac{1}{3}$ grain of Dial, $\frac{1}{2}$ grain of ethylmorphine and $9\frac{1}{2}$ grains of chlorbutol. (*Ciba, London.*)
- Hepa Simplex.**—Brand of liver extract. (*Bencard, London; Woolley, Manchester.*)
- Hepastab.**—Concentrated sterile solution of the anti-anæmic principles of mammalian liver. It is administered by intramuscular injection in doses of 2 or more millilitres. (*Boots, Nottingham.*)
- Hepatex.**—Preparation similar to Extractum Hepatis Liquidum, one fluid drachm being equivalent to 2 ounces of fresh liver. Modifications for administration by intramuscular or intravenous injection and compounded preparations are also available. (*Evans Sons Lescher and Webb, Liverpool.*)

Substances with Proprietary Trade-Names—Continued.

- Hepol.**—Extract of liver for oral administration. Modifications for administration by intramuscular or intravenous injection and compounded preparations are also available. (*Allen and Hanburys, London.*)
- Hexal.**—Hexamine sulphosalicylate in tablet form. It is used for the same purposes as hexamine in doses of 0.5 to 1 gramme (8 to 15 grains). (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Hogastrin.**—Liquid extract of freshly killed hogs' stomach for the treatment of pernicious anæmia. It is administered in doses of 1 to 2 fluid drachms. (*Giles Schacht, Bristol.*)
- Hoggex.**—Preparation of the desiccated mucous membrane of hogs' stomach containing the anti-anæmic principle. It is administered in doses of one-quarter those of desiccated whole stomach, and is supplied in capsules containing the equivalent of 1200 grains of whole fresh stomach. (*Paines and Byrne, London.*)
- Holadin.**—Extract of pancreas containing diastasic enzymes. (*Faurchald, Bros. and Foster, New York; Burroughs Wellcome, London.*)
- Hombreol.**—Biologically standardised preparation of the testicular hormone for administration by intramuscular injection in doses of 1 millilitre in the treatment of conditions arising from impaired internal secretion from the testes. (*Organon Laboratories, London.*)
- Hordine.**—Brand of Extractum Malti Liquidum. (*Oppenheimer, London.*)
- Hydnocreol.**—Preparation consisting of the ethyl esters of the fatty acids of hydnocarpus oil with 4 per cent. of creosote. (*Smith, Stamford, Calcutta.*)
- Hydropyrin.**—Brand of Lithi Acetylsalicylas. (*Richter, London.*)
- Hyperol.**—Solid compound of urea and hydrogen peroxide, stabilised with citric acid, containing the equivalent of 35 per cent. of H_2O_2 . It is supplied in powder or in tablets containing 1 gramme (15 grains). (*Richter, London; Berk, London.*)
- Hypophysin.**—Brand of Extractum Pituitarii Liquidum. (*Bayer Products, London.*)
- Ichthalbin.**—Compound of ichthammol and albumen. It is administered in cachets containing 1 gramme (15 grains) in the treatment of chronic intestinal disorders, and in eczema and other skin affections. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Ichthargen.**—Silver compound of Ichthyol containing 30 per cent. of silver. It is used in solution in the treatment of gonorrhœa. (*Cordes, Hermann, Hamburg; Ichthyol Co., London.*)
- Ichthoform.**—Condensation product of ichthammol and formaldehyde. It is administered as an intestinal antiseptic in doses of 0.1 to 0.3 gramme ($1\frac{1}{2}$ to 5 grains). (*Cordes, Hermann, Hamburg; Ichthyol Co., London.*)
- Ichthyol.**—Brand of Ichthammol. (*Cordes, Hermann, Hamburg; Ichthyol Co., London.*)
- Idozan.**—Solution containing 5 per cent. of colloidal iron, administered in doses of 1 to 4 fluid drachms. (*Serpens, Copenhagen; Coates and Cooper, London.*)
- Iglodine.**—Triiodoethylphenol. It is supplied in numerous forms for use as an antiseptic. (*Iglodine, Newcastle-on-Tyne.*)
- Impletol.**—Compound of diethyl-*p*-aminobenzoyl hydrochloride and caffeine. It is administered by subcutaneous or intramuscular injection for the relief of pain due to vasomotor disturbances. (*Bayer Products, London.*)
- Infundibulin.**—Brand of Extractum Pituitarii Liquidum. (*Evans Sons Lescher and Webb, Liverpool.*)

Substances with Proprietary Trade-Names—Continued.

Infundin.—Brand of Extractum Pituitarii Liquidum. (*Burroughs Wellcome, London.*)

Infundrenalin.—Combination of Infundibulin and adrenaline. It is supplied in two ampoules, the contents of which are mixed prior to administration, and is administered by hypodermic injection in doses of 0.5 to 1 millilitre for the relief of bronchial asthma and hay fever. (*Evans Sons Lescher and Webb, Liverpool.*)

Iodalbin.—An iodoprotein containing about 21.5 per cent. of iodine. It is administered in doses of 0.3 gramme (5 grains) or more as a substitute for inorganic iodides. (*Parke Davis, London.*)

Iodatol.—Iodised vegetable oil prepared in various strengths and administered in place of inorganic iodides. The 40 per cent. strength is used for X-ray visualisation. (*British Drug Houses, London*)

Iod-Calcium-Diuretin.—Combination of potassium iodide and Calcium-Diuretin used in the treatment of angina pectoris and asthma. It is supplied as powder, or in tablets containing $1\frac{1}{2}$ grains of potassium iodide and $7\frac{1}{2}$ grains of Calcium-Diuretin. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)

Iodeikon.—Brand of Iodophthaleinum. (*Mallinckrodt, St. Louis.*)

Iodex.—A non-staining ointment containing 4 per cent. of iodine. (*Menley and James, London.*)

Iodicin.—Calcium salt of iodoricinoleic acid. It is administered in place of inorganic iodides in the form of capsules containing 0.2 gramme (3 grains) equivalent to about 1 grain of iodine, or in the form of tablets with a chocolate base containing 0.03 gramme ($\frac{1}{2}$ grain) equivalent to about $\frac{1}{6}$ grain of iodine. (*Burroughs Wellcome, London.*)

Iodipin.—Iodised sesame oil prepared in various strengths and administered by the mouth or by intramuscular injection as a substitute for inorganic iodides. The 40 per cent. preparation is used as a contrast medium in X-ray diagnosis. (*Merck, Darmstadt; Napp, London.*)

Iodival.— α -Monoiodoisovalerylcarbamide. It is a sedative compound of iodine for internal administration in doses of 0.3 gramme (5 grains). (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)

Iodolysin.—Compound containing thiosinamine, 43 per cent., and iodine, 47 per cent. It is administered by injection, by the mouth and by local application in the treatment of rheumatoid arthritis. (*Allen and Hanburys, London.*)

Iodoprotein.—Preparation containing about 10 per cent. of iodine. It is administered in the form of tablets containing 0.3 gramme (5 grains) or 0.6 gramme (10 grains) in place of inorganic iodides. (*Martindale, London.*)

Iodo-Ray.—Brand of Iodophthaleinum. (*Martindale, London.*)

Iodostarin.—Iodine derivative of tariric acid containing about 47.5 per cent. of iodine. It is used in the form of tablets as a substitute for inorganic iodides. (*Hoffman-La Roche, London.*)

Iodsam.—Iodised oil containing 10 per cent. of iodine. It is administered in place of inorganic iodides, and is also supplied as an ointment containing 10 per cent. of iodine. (*Oppenheimer, London.*)

Iod-Tetragnost.—Brand of Iodophthaleinum. (*Merck, Darmstadt; Napp, London.*)

Ipecopan.—Preparation containing 0.0025 gramme ($\frac{1}{40}$ grain) of the total alkaloids of opium and 0.0005 gramme ($\frac{1}{200}$ grain) of emetine hydrobromide in tablet form. Each tablet is equivalent to 0.3 gramme (5 grains) of compound powder of ipecacuanha. (*Sandoz, London; Brooks and Warburton, London.*)

Isacen.—Diacetyldioxyphenylisatin. It is administered in the form of granules in the treatment of constipation. (*Hoffman-La Roche, London.*)

Substances with Proprietary Trade-Names—Continued.

- I-so-gel.**—Preparation consisting of a dried mucilage from vegetable seeds and used for the same purposes as Psyllium. (*Allen and Hanburys, London.*)
- Iso-Iodeikon.**—Sodium phenoltetraiodophthalein. It is administered by intravenous injection for the X-ray visualisation of the gall-bladder and simultaneous test of hepatic function. It may be given orally if X-ray visualisation of the gall-bladder alone is required. (*Mallinckrodt, St. Louis.*)
- Isolax.**—Diphenolisatin in the form of tablets containing 0.0005 gramme. It is administered in the treatment of constipation. (*Richter, London.*)
- Isin.**—Dihydroxyanthraquinone in the form of tablets containing 0.15 gramme ($2\frac{1}{2}$ grains) for use in the treatment of constipation. (*Bayer Products, London.*)
- Jothion.**—1 : 3-diiodopropane-2-ol, containing from 77 to 80 per cent. of iodine. It is used to obtain the systemic effects of iodine by external application. (*Bayer Products, London.*)
- Kafalgol.**—Combination of caffeine, 0.05 gramme, and calcium acetylsalicylate, 0.5 gramme, in tablet form. (*Richter, London.*)
- Kalmopyrin.**—Brand of Calcii Acetylsalicylas. (*Richter, London.*)
- Kaltron.**—Polyvalent vaccine administered by injection in doses of 0.5 to 1 millilitre (8 to 15 minims) in the prophylactic treatment of colds, influenza and catarrh. (*Bayer-Meister Lucius, Leverkusen; Saccharin Corporation, London.*)
- Kalzana.**—Tablets containing 0.5 gramme ($7\frac{1}{2}$ grains) of calcium sodium lactate. (*Therapeutic Products, London.*)
- Karvol.**—Chlorocavacrol in 5 per cent. solution for use as an antiseptic. (*British Colloids, London.*)
- Kathiolan.**—An ointment used for the same purposes as Unguentum Potassii Polysulphidi. (*Ferrosan, Copenhagen; C. Zimmermann, London.*)
- Kelene.**—Brand of Æthylis Chloridum. (*Société Parisienne d'Expansion Chimique, Paris.*)
- Kerocain.**—Brand of Procainæ Hydrochloridum. (*Kerfoot, Bardsley.*)
- Kharophen.**—Brand of Acetarsol. (*Burroughs Wellcome, London.*)
- Kharsivan.**—Brand of Arsphenamina. (*Burroughs Wellcome, London.*)
- Kharsulphan.**—Brand of Sulpharsphenamina. (*Burroughs Wellcome, London.*)
- Kinctine.**—Combination of Hectine and quinine hydrochloride in tablet form for administration in the treatment of hay fever, malaria and influenza. (*Mouneyrat, Villeneuve-la-Garenne; Anglo-French Drug Co., London.*)
- Koptalgos.**—De-narcotised preparation of opium containing 0.0375 per cent. of morphine. It is administered in doses of 0.3 to 2.5 millilitres (5 to 40 minims) in place of the tincture. (*Duncan Flockhart, Edinburgh.*)
- Krysolgan.**—Sodium salt of 4-amino-2-auromeraptolbenzol-1-carboxylic acid. It is given intravenously in gradually increasing doses from 0.0001 to 0.05 gramme ($\frac{1}{640}$ to $\frac{1}{2}$ grain) in the treatment of tuberculosis. (*Schering, London.*)
- Lacarnol.**—Extract of heart muscle prepared for oral or intramuscular administration in the treatment of angina pectoris. (*Bayer Products, London.*)
- Lactéol.**—Preparations containing lactic acid-forming bacilli in various forms for internal and external use. (*Boucard, Paris; Wilcox Jozeau, London.*)
- Lactobacilline.**—Preparation containing lactic acid-forming bacilli. (*Darasse, Nanterre; Wilcox Jozeau, London.*)
- Lævo-Glaucosan.**—Solution containing 2 per cent. each of synthetic *l*-adrenaline and of active methylaminoacetatechol (adrenalone). It is a powerful miotic used in the form of eye-drops, preceded by a local anæsthetic, in the treatment of chronic glaucoma. (*Wähm, Spangenberg; Saccharin Corporation, London.*)

Substances with Proprietary Trade-Names—Continued.

- Laxase.**—Brand of Agar in tablet form. (*Allen and Hanburys, London.*)
- Laxoin.**—Brand of Phenolphthaleinum. (*Oppenheimer, London.*)
- Lemolac.**—Brand of Hydrargyri Subchloridum in a very light form. (*Howards, Ilford.*)
- Lenigallol.**—Pyrogallol triacetate. It is used as an ointment, containing from 1 to 10 per cent., the strength being gradually increased, in the treatment of eczema. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Levurine.**—Preparation of dried beer yeast. It is administered by the mouth or by intramuscular injection in the treatment of staphylococcal infections. (*Couturieux, Paris; Wilcox Jozeau, London.*)
- Lipamin.**—Preparation of the hormone of the corpus luteum similar in effect to oestrin. It is administered orally or by injection in the treatment of amenorrhœa and allied conditions. (*Paines and Byrne, London.*)
- Lipiodol.**—Iodised poppyseed oil. It contains 10 or 40 per cent. of iodine in organic combination and is used as a contrast medium in X-ray diagnosis. (*Guerbet, Paris; Bengué, London.*)
- Lipoiodine-Ciba.**—Ethyl ester of diiodobrassicic acid containing 41 per cent. of iodine. It is administered orally in the form of tablets in doses of 0·3 to 2 grammes (5 to 30 grains) in place of inorganic iodides. (*Ciba, London.*)
- Lipo-Lutin.**—Protein-free extract containing the lipoids of the corpus luteum. (*Parke Davis, London.*)
- Litmopyrin.**—Brand of Lithii Acetylsalicylas. (*Bishop, London.*)
- Livadex.**—Concentrated liquid extract of liver containing in 1 fluid ounce the active principles of 8 ounces or raw liver. (*British Drug Houses, London.*)
- Liver Extract Fraction A5.**—A fraction of liver extract for oral administration containing the anti-anæmic principle, and representing about 20 times its weight of fresh liver. (*Sharp and Dohme, London.*)
- Liveroid.**—Brand of liquid extract of liver, flavoured for oral administration. (*Oxo, London.*)
- Livogen.**—A liquid preparation containing in each fluid ounce the active principles of 4 ounces of fresh liver and 1 ounce of fresh yeast, with 5 grains of hæmoglobin. It is administered in the treatment of anæmia and debility. (*British Drug Houses, London.*)
- Livron.**—Compound liver extract containing iron for use in the treatment of secondary anaemias. (*Boots, Nottingham.*)
- Lodal.**—Chloride of 6:7-dimethoxy-2-methyl-3:4-dihydroisoquinolinium, used like cotarnine and hydrastinine to control uterine hæmorrhage. (*Burroughs Wellcome, London.*)
- Loretin.**—Iodoxyquinolinesulphonic acid mixed with sodium bicarbonate. It occurs as a yellow powder soluble in water and is administered as an antiseptic, particularly in the treatment of amœbic dysentery, in doses of 1 gramme (15 grains) three times a day. It may also be administered by rectal injection of 200 millilitres of a 2 per cent. solution. (*Schuchardt, Grolitz.*)
- Lorol.**—A mixture of alcohols obtained by the hydrogenation of the fatty acids of certain fixed oils. The sodium salts of sulphonates of the alcohols (Sulphonated Lorol) are used widely as detergents. (*Ronschein and Moore, London.*)
- Luminal.**—Brand of Phenobarbitonum. (*Bayer Products, London.*)
- Luminal Sodium.**—Brand of Phenobarbitonum Solubile. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Luteolipoids.**—Preparation of the hormone of the corpus luteum which is antagonistic to oestrin. It is administered orally or by injection in the treatment of menorrhagia and allied conditions. (*Paines and Byrne, London.*)
- Lycetol.**—Dimethylpiperazine tartrate. It is given in doses of 8 to 30 grains in the treatment of gouty and rheumatic conditions. (*Bayer Products, London.*)
- Magisal.**—Brand of Magnesium Acetylsalicylate. (*Martindale, London.*)
- Magnesium-Perhydrol.**—Brand of Magnesii Peroxidum (15 or 20 per cent. of MgO_2). (*Merck, Darmstadt; Napp, London.*)
- Magnozon.**—Brand of Magnesii Peroxidum (25 per cent. of MgO_2). (*Richter, London.*)
- Marmite.**—Extract of yeast containing the vitamin B complex. (*Marmite Food Extract Co., London.*)
- Mastisol.**—Compound solution containing mastic in benzene. It is used as an application to wounds. (*Schubert, Berlin.*)
- Matronax.**—Compound tablet containing $\frac{1}{2}$ grain of ovarian substance with Thyraden, Bromural and Calcium-Diuretin. It is administered in the treatment of affections associated with the menopause. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Medinal.**—Brand of Barbitonum Solubile. (*Schering, London.*)
- Menformon.**—Brand of ketohydroxyoestrin (see Oestrinum). It is supplied in the form of tablets of various strengths for oral administration, in aqueous solution containing 0.0001 gramme (1000 Doisy rat units) per millilitre, in oily solution containing 10,000 units per millilitre, or in the form of suppositories containing 1000 units. (*Organon Laboratories, London.*)
- Mercolloid.**—Suspension of colloidal mercuric sulphide for intramuscular injection in the treatment of syphilis. (*Biochemical Laboratories, Locarno; Coates and Cooper, London.*)
- Mercurocol.**—Brand of Mercurochromum. (*Evans Sons Lescher and Webb, Liverpool.*)
- Mercurome.**—Brand of Mercurochromum. (*Martindale, London.*)
- Meroxyl.**—Mixture containing about 50 per cent. of the sodium salt of 2:4-dihydroxy-3:5-dihydroxymercuribenzophenone-2'-sulphonic acid. It is used as an antiseptic for the irrigation of wounds, as a wet dressing (1 in 1000), and for prophylactic use in the genito-urinary tract (1 in 200). (*Hynson, Westcott and Dunning, Baltimore.*)
- Mesotan.**—Methoxymethyl salicylate, $\text{C}_6\text{H}_4(\text{OH})\text{COO}\cdot\text{CH}_2\text{OCH}_3$. It is used in the form of a paint, diluted with 1 to 4 parts of olive or other oil, as a counter-irritant. (*Bayer Products, London.*)
- Mesurool.**—Basic bismuth methoxyhydroxybenzoate. It is administered intramuscularly as a 20 per cent. emulsion in the treatment of syphilis. (*Bayer Products, London.*)
- Metagen.**—Preparation containing water-soluble and fat-soluble vitamins in extract form. (*Parke Davis, London.*)
- Metaphen.**—4-Nitro-3:5-bisacetoxymercuri-2-cresol. It occurs as an odourless and tasteless powder insoluble in water but readily soluble in dilute alkalis. It is used as a non-irritant antiseptic in strengths of from 1 to 10,000 to 1 in 1000. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Metarsenobillon.**—Brand of Sulpharsphenamina. (*May and Baker, London.*)
- Methyl Adronol.**—Brand of Methylcyclohexanolum. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Methyl-Aspirodine.**—Methyl acetyliodosalicylate,. It occurs as a white, crystalline compound melting at 40° and containing the equivalent of 40 per cent. of iodine and 56 per cent. of acetylsalicylic acid. It is applied externally in the form of an ointment or liniment in the treatment of painful rheumatic affections. (*Martindale, London.*)
- Metramine.**—Brand of Hexamina. (*Oppenheimer, London.*)
- Migrainine.**—Brand of Phenazoni et Caffeina Citras. (*Bayer Products, London.*)
- Mitigal.**—Dimethyldiphenylenedisulphide, a liquid application for the topical treatment of scabies and other skin affections. (*Bayer Products, London.*)
- Moogrol.**—Brand of Oleum Hydnocarpi Æthylicum. (*Burroughs Wellcome, London.*)
- Moranyl** (Fourneau 309).—The symmetrical urea of di-sodium *m*-aminobenzoyl-*m*-amino-*p*-methylbenzoyl-1-naphthylamino-4:6:8-trisulphonate, administered in the treatment of trypanosomiasis as a 10 per cent. aqueous solution in doses up to 10 millilitres by subcutaneous or intravenous injection. (*Société Parisienne d'Expansion Chimique, Paris.*)
- Multibral.**—Sodium monobromoleate in the form of coated pellets. It is administered as a substitute for bromides. (*Norgine, Prague; Napp, London.*)
- Mycosin.**—Brand of desiccated yeast. (*Richter, London.*)
- Myocrisin.**—Preparation of gold sodium thiomalate administered by intramuscular injection for the same purposes as Auri et Sodii Thiosulphas. (*May and Baker, London.*)
- Myosalvarsan.**—Brand of Sulpharsphenamina. (*Bayer Products, London.*)
- Myoston.**—Preparation of heart muscle extract for administration by subcutaneous or intramuscular injection, or orally, in the treatment of angina pectoris. (*Hemming, Berlin; Pharmaceutical Products, London.*)
- Narcophin.**—Morphine narcotine meconate. It occurs as yellowish crystals, containing about 30 per cent. of morphine, incompletely soluble in water. It is administered as a hypnotic in doses of 0.015 to 0.03 gramme ($\frac{1}{4}$ to $\frac{1}{2}$ grain). (*Boehringer, Mannheim; Mertens, London.*)
- Narcotile.**—Brand of Æthylis Chloridum. (*Bengué, London.*)
- Nargol.**—Combination of silver with nucleinic acid from yeast, containing 10 per cent. of silver. It may be used in the form of 0.25 to 10 per cent. solution or in bougies containing 1 or 2 per cent. (*Parke Davis, London.*)
- Natibaine.**—Solution containing digitoxin and ouabain. 15 drops contain $\frac{1}{100}$ grain of Digitaline (Nativelle) and $\frac{1}{300}$ grain of ouabain. It is administered in doses of 10 to 30 drops during twenty-four hours. (*Nativelle, Paris; Wilcox Jozeau, London.*)
- Neboline.**—Brand of Paraffinum Liquidum Leve. (*Oppenheimer, London.*)
- Nembutal.**—Sodium ethylmethylbutylbarbiturate. It is administered orally in doses of 0.03 to 0.2 gramme ($\frac{1}{2}$ to 3 grains) as a sedative and hypnotic, particularly for pre-operative narcosis. It is also administered intravenously as an anæsthetic. (*Abbott, Chicago; Pharmaceutical Products, London.*)
- Neobismosalvan.**—Suspension of quinine and bismuth iodide and lecithin in olive oil. It is administered by intramuscular injection in the treatment of syphilis. (*Richter, London.*)
- Neo-Bornyval.**—*iso*Valerylglycollic ester of borneol. It is administered in the form of perles containing 0.25 gramme ($3\frac{1}{2}$ grains) in the treatment of nervous gastric and other affections. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)

Substances with Proprietary Trade-Names - *Continued.*

Neobovinine.—Combination of liver extract and hæmoglobin for use in the treatment of anæmias. (*Petrolagar, London.*)

Neocaine.—Brand of Procaine: Hydrochloridum. (*Corbière, Paris; Anglo-French Drug Co., London.*)

Neo-Cardyl.—Bismuth butylthiolaurate prepared in oily solution for intramuscular injection in doses of 1·5 millilitres in the treatment of syphilis. (*May and Baker, London.*)

Neo-Dmegon.—Anti-gonococcal vaccine prepared from a number of different strains of the gonococcus and synococcus. It is administered by intramuscular or subcutaneous injection in doses of 1 millilitre in the treatment of the complications of gonorrhœa. (*May and Baker, London.*)

Neo-Dmesta.—Anti-staphylococcal vaccine prepared from a number of different strains of staphylococci and *Micrococcus tetragenus*. It is administered by intramuscular or subcutaneous injection in doses of 1 millilitre in the treatment of staphylococcal infections. (*May and Baker, London.*)

Neo-Dmetys.—Vaccine prepared from the bacillus of Bordet and Gengou and administered by intramuscular or subcutaneous injection in the curative and prophylactic treatment of whooping cough. (*May and Baker, London.*)

Neodorm.— α -isoPropyl- α -bromobutyramide in tablet form. It is used as a sedative and hypnotic in doses of 5 to 15 grams. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)

Neo-Hexal.—Compound of hexamine, 1 molecule, and sulphosalicylic acid, 2 molecules, in tablet form. It is used for the same purposes as hexamine in doses of 0·5 to 1 gramme (8 to 15 grains). (*Reidel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)

Neo-Hormonal.—Extract of spleen administered by intravenous or intramuscular injection in the treatment of chronic constipation and post-operative intestinal paralysis. (*Schering, London.*)

Neo-Hydriol.—Iodised ester of the fatty acids of poppy-seed oil containing 40 per cent. of iodine and having a low viscosity. It is used for the X-ray visualisation of the bronchi, spinal cord, kidneys and other organs. (*May and Baker, London.*)

Neohydrosyrin.—Brand of Magnesi Acetysalicylas. (*Richter, London.*)

Neokharsivan.—Brand of Neoarsphenamina. (*Burroughs Wellcome, London.*)

Neolyse.—Preparation of silica and magnesium compounds. It is supplied in cachets containing 0·5 gramme and in ampoules of solution for injection, and is used in the treatment of malignant growths. (*Ferné, Paris; Anglo-French Drug Co., London.*)

Neonal.—*n*-Butylethylbarbituric acid. It is administered in doses of from 0·05 to 0·1 gramme ($\frac{3}{4}$ to $1\frac{1}{2}$ grains) as a sedative and hypnotic. (*Abbott, Chicago; Pharmaceutical Products, London.*)

Neophenoquin.—Lithium compound of cinchophen in tablet form. (*Southall Bros. and Barclay, Birmingham.*)

Neo-Protosil (Neo-Silvol).—Preparation of colloidal silver iodide, 20 per cent., with a soluble protein base. It is used in aqueous solution in the treatment of inflammatory conditions of mucous membranes. (*Parke Davis, London.*)

Neo-Reargon.—Compound of silver and anthraquinone glycosides containing 14 per cent. of silver. It is used in the treatment of gonorrhœa. (*Norgue, Prague; Napp, London.*)

Neo-Salvarsan.—Brand of Neoarsphenamina. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

Neo-Silver Salvarsan.—Combined silverarsphenamine and neoarsphenamine. 0·3 gramme corresponds in therapeutic value to approximately 0·4 gramme of Neoarsphenamina. (*Bayer Products, London.*)

Neostam.—Nitrogen-glycoside of sodium *p*-aminophenylstibinate. It is injected intravenously in the treatment of kala-azar. (*Burroughs Wellcome, London.*)

Neostibosan.—Diethylamine *p*-aminophenylstibinate. It is injected intravenously in the treatment of kala-azar. (*Bayer Products, London.*)

Neo-trepol.—Isotonic aqueous suspension of precipitated bismuth containing in 1 millilitre 0·1 gramme of bismuth. (*Chenal et Douilhet, Paris; Anglo-French Drug Co., London.*)

Neotropin.—2-Butyloxy-2':6'-diamino-5:5'-azopyridine. It is administered orally as a urinary antiseptic in the treatment of genito-urinary infections. (*Schering, London.*)

Neptal.—*o*-Hydroxymercuripropylamidocarboxyphenoxyacetic acid. It is used as a diuretic in the treatment of cardiac or renal oedema and is administered by injection in doses of 1 millilitre (15 minims) containing 0·035 gramme ($\frac{1}{2}$ grain) of mercury. (*May and Baker, London.*)

Nepenthe.—Alcoholic preparation of opium containing 0·84 per cent. w/v of anhydrous morphine. It is used for the same purposes as Tinctura Opii. (*Ferris, Bristol.*)

Neurinase.—Preparation of soluble barbitone and extract of valerian. It is administered as a hypnotic and sedative in the form of tablets, or in solution containing in each fluid drachm 3 grains of soluble barbitone and $\frac{1}{2}$ grain of extract of valerian. (*Genevrier, Nevilly; Wilcox Jozeau, London.*)

Neutralon.—Synthetic aluminium sodium silicate. It is administered in doses of 2 to 4 grammes ($\frac{1}{2}$ to 1 drachm) in the treatment of hyperacidity and gastric or duodenal ulceration. (*Schering, London.*)

Nevrosthénic (Ampoules and Drops).—Solutions containing sodium glycerophosphate, and strychnine cacodylate for use in the treatment of neurasthenia. (*Frasse, Paris; Wilcox Jozeau, London.*)

Nipabenzyl.—Benzyl ester of *p*-hydroxybenzoic acid. It is used as a preservative of pharmaceutical preparations in a concentration of 0·01 to 0·06 per cent. It is very slightly soluble in water, but readily soluble in alcohol, glycerin and oils. The sodium derivative is readily soluble in water. (*Penner, Berlin; Samuelson, London.*)

Nipagin A.—Ethyl ester of *p*-hydroxybenzoic acid. It is used as a preservative of creams and lotions in a concentration of 0·05 to 0·15 per cent. (*Penner, Berlin; Samuelson, London.*)

Nipagin M.—Methyl ester of *p*-hydroxybenzoic acid. It is used as a preservative of pharmaceutical preparations in a concentration of 0·05 to 0·2 per cent. It is slightly soluble in water (1 in 400) and readily soluble in oils (1 in 40). (*Penner, Berlin; Samuelson, London.*)

Nipakombin.—Water-soluble ester of *p*-hydroxybenzoic acid. It is used as a preservative in a concentration of 0·04 to 2 per cent. (*Penner, Berlin; Samuelson, London.*)

Nipasol M.—Propyl ester of *p*-hydroxybenzoic acid. It is used as a preservative of pharmaceutical preparations. It is very slightly soluble in water, but readily soluble in oils and organic solvents. The sodium derivative is readily soluble in water. (*Penner, Berlin; Samuelson, London.*)

Nirvanol.— $\gamma\gamma'$ -phenylethylhydantoin. It is administered in the form of powder or tablets in doses of 0·15 to 0·45 gramme ($\frac{1}{2}$ to 7 grains) as a sedative and in the treatment of chorea. (*Heyden, Dresden; Braun, London.*)

Substances with Proprietary Trade-Names—Continued.

- Nizin.**—Brand of Zinci Sulphanilas. (*Burroughs Wellcome, London.*)
- Noctal.**—*iso*Propylbromopropanylbarbituric acid in tablet form. It is administered as a sedative and hypnotic in doses of 0.1 to 0.2 gramme ($1\frac{1}{2}$ to 3 grains). (*Reidel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Norit.**—Brand of Carbo Activatus. (*Norit, Amsterdam; C. Zimmermann, London.*)
- Normacol.**—Preparation of the desiccated mucilage of a species of *Astragalus* with an extract of a species of *Frangula*. It is administered in doses of one to two drachms in the treatment of constipation. (*Norgine, Prague; Napp, London.*)
- Novalgin.**—Sodium phenyldimethylpyrazolonmethylaminomethanesulphonate. It is administered orally in the form of tablets or powder in doses of 0.5 gramme ($7\frac{1}{2}$ grains) or by injection as a 50 per cent. solution in doses of 1 to 2 millilitres (15 to 30 minims), in the treatment of rheumatic diseases. (*Bayer Products, London.*)
- Novarsan.**—Brand of Neoarsphenamina. (*Allen and Hanburys, London.*)
- Novarsenobillon.**—Brand of Neoarsphenamina. (*May and Baker, London*)
- Novaspirin.**—Brand of Acidum Citrosalicum. (*Winthrop, New York.*)
- Novasurol** (Merbaphen).—Double salt of sodium mercurichlorophenylxyacetate and barbitone containing about 34 per cent. of mercury. It is administered as a diuretic in doses of 0.5 to 2 millilitres of a 10 per cent. solution. (*Winthrop Chemical Co., New York; Bayer Products, London.*)
- Novatophan.**—Methyl ester of 2-phenylquinoline-4-carboxylic acid. It is used for the same purposes as Neocinchophenum. (*Schering, London.*)
- Novocain.**—Brand of Procainæ Hydrochloridum. (*Bayer-Meister Luctus, Leverkusen; Saccharin Corporation, London.*)
- Novocol.**—Sodium guaiacolphosphate. It is administered in the form of tablets or syrup in the treatment of catarrh and pulmonary affections. (*Richter, London.*)
- Novostab.**—Brand of Neoarsphenamina. (*Boots, Nottingham.*)
- Nov-Umbrose.**—Prepared barium sulphate for use as a barium meal. (*Allen and Hanburys, London.*)
- Nujol.**—Brand of Paraffinum Liquidum. (*Anglo-American Oil Co., New Jersey; Stemco, London.*)
- Nyctal.**—Brand of Carbromalum. (*Sitsa, Paris; Roberts, London.*)
- Oestroform.**—Brand of ketohydroxyoestrin (see Oestrinum). It is supplied for oral administration in the form of tablets each containing 1000 units, or for administration by injection as a solution containing 1000 or 10,000 units per millilitre. (*British Drug Houses, London.*)
- Okistypitin.**—Brand of Cotarninæ Chloridum. (*Richter, London.*)
- Omnadin.**—Vaccine for use in the treatment of various diseases by non-specific protein therapy. (*Bayer Products, London.*)
- Omnopon** (Pantopon).—Brand of Papaveretum. (*Hoffman-La Roche, London.*)
- Opacin.**—Brand of Iodophthaleinum. (*May and Baker, London.*)
- Opacol.**—Preparation of iodophthalein for oral administration as a single dose. (*May and Baker, London.*)
- Opoidine.**—Brand of Papaveretum. (*Macfarlan, London.*)
- Optalidon.**—Combination of 0.05 gramme of Sandoptal, 0.125 gramme of amidopyrine and 0.025 gramme of caffeine in tablet form. It is administered as a sedative and hypnotic in doses of 1 to 3 tablets. (*Sandoz, London; Brooks and Warburton, London.*)

Substances with Proprietary Trade-Names—Continued.

- Optarson.**—Solution of ammonium heptinchlorarsenate and strychnine nitrate. It is administered by subcutaneous injection as a tonic in doses of 1 millilitre, containing 0.004 gramme of As_2O_3 in organic combination and 0.001 gramme of strychnine nitrate. (*Bayer Products, London.*)
- Optinoktin.**—Combination of phenobarbitone, 0.1 gramme ($1\frac{1}{2}$ grains), bromisovalerylurea, 0.2 gramme (3 grains), and amidopyrine, 0.2 gramme (3 grains), in tablet form. (*Richter, London.*)
- Optochin.**—Brand of Æthylhydrocupreina. (*Howards, Ilford.*)
- Orargol.**—Colloidal solution of gold and silver for oral, intramuscular, or intravenous administration, or for local application as an anti-infective agent. (*Anglo-French Drug Co., London.*)
- Orarsan.**—Brand of Acetarsol. (*Boots, Nottingham.*)
- Orisol.**—Berberine acid sulphate in 2 per cent. solution for infiltration injection in the treatment of antimony-resistant oriental sore. (*May and Baker, London.*)
- Orthoform** (New Orthoform).—Brand of Orthocaina. (*Bayer Products, London.*)
- Ortizon.**—Solid compound of hydrogen peroxide containing about 35 per cent. of H_2O_2 . A 10 per cent. solution is approximately equivalent to solution of hydrogen peroxide. (*Bayer Products, London.*)
- Ostelin.**—Concentrate of vitamin D, miscible with water. It contains 5000 international units of vitamin D per millilitre, and is also available in the form of tablets, each containing 500 units of the vitamin, or emulsion, containing 2800 units per fluid ounce. (*Glaxo Laboratories, London.*)
- Otosclerol.**—Combination of cimicifugin, 6.66 per cent., bromine, 36.3 per cent., and phosphates, in tablet form. It is administered in the treatment of deafness. (*Muchener Pharmazeutische Fabrik, Munich; Coates and Cooper, London.*)
- Otalgan.**—5 per cent. solution of phenyldimethylpyrazolone in anhydrous glycerin. It is instilled into the ear in the treatment of middle-ear diseases. (*Sachs Serumwerk, Dresden; Napp, London.*)
- Ovarnon.**—Desiccated ovarian substance in tablet form, each tablet containing 0.15 gramme with 10 units of Menformon. (*Organon Laboratories, London.*)
- Overaden.**—Ovarian extract in tablet form, each tablet containing the equivalent of about 0.5 gramme of fresh gland. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Pacyl.**—Preparation containing 0.005 gramme ($\frac{1}{40}$ grain) of a choline derivative in tablet form. It is administered by the mouth as a vasodilator in the treatment of arterial hypertension and its sequelæ. (*Wiernik, Berlin; Coates and Cooper, London.*)
- Padutin.**—Preparation of a vasomotor hormone obtained from the pancreas. It is used in the treatment of angiospasm, Raynaud's disease and other affections. (*Bayer Products, London.*)
- Pancrobilin.**—Preparation of pancreatic enzymes with bile salts. It is administered in the form of pills or liquid in the treatment of constipation. (*Reed and Carnrick, Jersey City; Coates and Cooper, London.*)
- Pandigal.**—Preparation of the glycoside, lanadigin, obtained from *Digitalis lanata*. It is supplied in the form of tablets, solution, ampoules, or suppositories for oral, intravenous, or rectal administration in doses of 0.0002 to 0.0004 gramme. (*Beiersdorf, Welwyn Garden City.*)
- Panflavin.**—Euflavine in tablet form, to be dissolved slowly in the mouth in the treatment of suppurating conditions of the mouth and throat. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Pantheric** (Tablets).—Enteric-coated tablets containing 5 grains of triple-strength pancreatin. (*Parke Davis, London.*)
- Panthesine**.—N-diethyl-leucinol ester of *p*-aminobenzoic acid for use as a local anæsthetic in various strengths from 0·2 to 10 per cent. (*Sandoz, London; Brooks and Warburton, London.*)
- Pantocain** (Spinocain).—*p*-Butylaminobenzoyldimethylaminoethanol hydrochloride. It is used as an anæsthetic, particularly for the production of spinal, lumbar and surface anæsthesia. A viscous solution is supplied as "Pantocain L." (*Bayer Products, London.*)
- Paracalcin**.—Combination of $\frac{1}{10}$ grain of biologically standardised parathyroid and 3 grains of calcium lactate in tablet form. (*Endocrines, Watford.*)
- Paranephrin**.—Brand of Liquor Adrenalinae Hydrochloridi. (*Merck, Darmstadt; Napp, London.*)
- Paraphakin** (Euphakin).—Combination of hormones in tablet form for oral administration in the treatment of senile cataract. (*Wiernik, Berlin; Coates and Cooper, London.*)
- Para-thor-mone**.—Brand of Extractum Parathyroidei. (*Eli Lilly, London.*)
- Parenex**.—Concentrated extract of liver administered by injection. It is supplied in 2 millilitre ampoules containing the equivalent of 9000 grains of fresh liver. (*Paines and Byrne, London.*)
- Paroidin**.—A biologically standardised parathyroid extract prepared for subcutaneous or intramuscular injection. (*Parke Davis, London.*)
- Paroleine**.—Brand of Paraffinum Liquidum or of Paraffinum Liquidum I.e.v.e. (*Burroughs Wellcome, London.*)
- Parosan**.—8-Acetyl-amino-3-hydroxy-1 : 4-benzisoxazine-6-arsonic acid, administered in the form of tablets containing 0·25 gramme (4 grains) in the treatment of disseminated sclerosis. (*May and Baker, London.*)
- Pavon**.—Preparation of total alkaloids of opium, containing 25 per cent. of morphine. It is supplied in various forms for oral or subcutaneous administration for the same purposes as Papaveretum. (*Ciba, London.*)
- Pavopin**.—Brand of Papaveretum. (*T. and H. Smith, London.*)
- Pellidol**.—Diacetylaminoazotoluol, a dark red powder, easily soluble in oils, fats and organic solvents, insoluble in water. It is used as a non-staining alternative to Rubrum Scarlatinum. (*Bayer Products, London.*)
- Pentnucleotide** (Nucleotide K.96).—A mixture of the sodium salts of pentose nucleotides. It is administered by intramuscular injection in the treatment of aggranulocytic angina and similar conditions. (*Smith, Kline and French, Philadelphia; Menley and James, London.*)
- Peptalmine**.—Preparation of meat and fish peptones with extracts of eggs, milk, and wheat flour. It is administered orally in the treatment of anaphylactic disorders. (*Scientia, Paris; Wilcox Jozeau, London.*)
- Per-Abrodil**.—3 : 5-Diiodo-4-pyridon-N-acetate of diethanolamine, containing 51·8 per cent. of iodine. It is supplied as a 35 per cent. aqueous solution for use in intravenous pyelography. (*Bayer Products, London.*)
- Percainal**.—Ointment containing 1 per cent. of Percaine with solution of hamamelis and aluminium formate. It is used as an antipruritic and analgesic application in the treatment of certain skin affections. (*Ciba, London.*)
- Percaine** (Nupercaine).—Hydrochloride of α -butylloxycinchoninic acid diethylethylenediamide, occurring as an odourless, tasteless, crystalline compound softening at 90° and melting at 97°. It is readily soluble in water forming a neutral solution, and is used in various strengths as a local anæsthetic, and for infiltration and spinal anæsthesia. (*Ciba, London.*)

Substances with Proprietary Trade-Names—Continued.

- Perhepar.**—Concentrated extract of liver supplied in the form of powder, of which 1 gramme is equivalent to 100 grammes of fresh liver, or as a solution, of which 10 millilitres is equivalent to 100 grammes of fresh liver. (*Richter, London.*)
- Perhydrit.**—Solid compound of urea and hydrogen peroxide containing 35 per cent. of H_2O_2 . A 10 per cent. solution is approximately equivalent to solution of hydrogen peroxide. (*Merck, Darmstadt; Napp, London.*)
- Perhydrol.**—30 per cent. solution of hydrogen peroxide (100 volumes). (*Merck, Darmstadt; Napp, London.*)
- Perichthol.**—Brand of Ichthammol. (*British Drug Houses, London.*)
- Peristaltin.**—Active glycoside of cascara sagrada. It is administered orally in the form of tablets, or by hypodermic injection, in the treatment of constipation. (*Ciba, London.*)
- Pernæmon.**—Protein-free fraction of mammalian liver, containing the anti-anæmic principle, prepared for intramuscular injection. 1 millilitre, representing 5 grammes of fresh liver, when administered by injection is equivalent to 500 grammes of fresh liver. It is also prepared for oral administration. (*Organon Laboratories, London.*)
- Pernæmon Forte.**—Five times concentrated form of Pernæmon for treatment at long intervals. (*Organon Laboratories, London.*)
- Pernocton.**—Sodium salt of secondary butyl- β -bromallylbarbituric acid. It is supplied in 10 per cent. aqueous solution for use as a sedative and hypnotic and is administered by slow intravenous injection in doses varying, according to the patient, from 1 millilitre per 12.5 kilograms to 1 millilitre per 15 kilograms body weight. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Peronin.**—Brand of Benzylmorphinæ Hydrochloridum. (*Merck, Darmstadt; Napp, London.*)
- Phanodorm.**—Cyclohexenylethylbarbituric acid (cyclobarbital). It is administered as a mild hypnotic in doses of 0.1 gramme ($1\frac{1}{2}$ grains). (*Bayer Products, London.*)
- Phenalgin.**—Preparation containing acetanilide as the active constituent. It is administered in doses of 0.3 to 1 gramme (5 to 15 grains). (*Etna Chemical Co., London; Pearson, Mitcham.*)
- Phenoquin.**—Brand of Cinchophenum. (*Southall Bros. and Barclay, Birmingham.*)
- Phenyl-Aspriodine.**—Acetylidosalol. It is administered in doses of 0.3 gramme (5 grains) in the treatment of rheumatic conditions and as an intestinal antiseptic. (*Martindale, London.*)
- Phenyl-Sedasprin.**—Acetyl bromosalol. It is administered in doses of 0.3 gramme (5 grains) in the treatment of rheumatic conditions and as a bactericide in urinary affect ons. (*Martindale, London.*)
- Phytin.**—Calcium and magnesium salt of inositol hexaphosphoric acid. It is administered in the form of tablets, granules, or powder in the treatment of neurasthenia and debility. (*Ciba, London.*)
- Pinol.**—Brand of Oleum Pini Pumilionis. (*Burroughs Wellcome, London.*)
- Pitalin.**—Pituitary (posterior lobe) extract containing 5 units in 1 millilitre, with 0.0005 gramme of adrenaline. (*Paines and Byrne, London.*)
- Pitibulin.**—Brand of Extractum Pituitarii Liquidum. (*Allen and Hanburys, London.*)
- Pitocin.**—Preparation containing the oxytocic principle of Extractum Pituitarii Liquidum. (*Parke Davis, London.*)
- Piton.**—Brand of Extractum Pituitarii Liquidum. It is also supplied as a powder containing 1 unit per 0.001 gramme. (*Organon Laboratories, London.*)

Substances with Proprietary Trade-Names—Continued.

- Pitoxylin.**—Brand of Extractum Pituitarii Liquidum. (*Oxo, London.*)
- Pitressin.**—Preparation containing the pressor principle of Extractum Pituitarii Liquidum. (*Parke Davis, London.*)
- Pituchinol.**—Preparation containing in 1 millilitre 3 units of pituitary (posterior lobe) extract and 1 gramme of quinine. (*Homburg, Frankfurt; Spicer, London.*)
- Pituitrin.**—Brand of Extractum Pituitarii Liquidum. (*Parke Davis, London.*)
- Planadalin.**—Brand of Carbomalum. (*May and Baker, London.*)
- Planocaine.**—Brand of Procainæ Hydrochloridum. (*May and Baker, London.*)
- Planochrome.**—Brand of Mercurochromum. (*May and Baker, London.*)
- Plasmoquine.**—N-diethylaminoisopentyl-8-amino-6-methoxyquinoline. It is administered in tablet form in the treatment of malaria. (*Bayer Products, London.*)
- Plasmoquine Compound.**—Combination of 0.01 gramme of Plasmoquine and 0.125 gramme of quinine sulphate in tablet form. (*Bayer Products, London.*)
- Plastic X.**—Brand of Tricresylis Phosphas. (*Boake Roberts, Stratford.*)
- Pollaccine.**—Vaccine prepared from *Phleum pratense* for the prophylaxis and treatment of hay fever. (*Parke Davis, London.*)
- Pollantin.**—Serum obtained from animals which have been treated with a preparation of the pollen-grains of various species of *Gramineæ*. It is prepared in various forms for use in the treatment of hay fever. (*Schimmel, Leipzig; Willous, Francis, Butler and Thompson, London.*)
- Polyglandin.**—Polyglandular extract administered orally or by injection in the treatment of neurasthenia and other diseases. (*Allen and Hanburys, London.*)
- Pragmoline.**—Acetylcholine bromide, supplied as a stable solution in two strengths containing respectively 6 per cent. and 12.5 per cent. (*May and Baker, London.*)
- Pregnyl.**—Anterior pituitary-like hormone extracted from the urine of pregnant women. It is supplied for oral administration in the form of tablets each containing 90 rat units, or, for administration by injection, in ampoules containing 30 or 100 rat units. (*Organon Laboratories, London.*)
- Progynon.**—Biologically standardised preparation containing ketohydroxyoestrin (see Oestrinum). (*Schering, London.*)
- Prokliman.**—Ovarian hormone compound containing also Peristaltin, nitroglycerin, amidopyrine and caffeine sodium salicylate, in tablet form. It is administered in the treatment of menopausal disturbances. (*Ciba, London.*)
- Prolan.**—Standardised preparation containing the anterior pituitary hormone. It is administered orally in the form of pellets, each containing the equivalent of 150 rat units, or by intramuscular injection of a solution of the powder, which is supplied in dry ampoules containing the equivalent of 100 rat units. (*Bayer Products, London.*)
- Proliferae.**—Preparation of yeast supplied in 2.5 millilitre ampoules containing 130 to 140 million cells. It is administered orally for the same purposes as *Cerevisiæ Fermentum*. (*Anglo-French Drug Co., London.*)
- Prominal.**—N-methylethylphenylmalonylurea. It is administered in the treatment of epilepsy in doses of 0.2 to 0.4 gramme daily. (*Bayer Products, London.*)
- Propidex.**—Ointment containing a mixed vaccine of streptococci, staphylococci and *B. pyocyaneus*. It is applied locally in the treatment of pyogenic surface lesions. (*May and Baker, London.*)
- Protargol.**—Brand of Argenti Proteinæ. (*Bayer Products, London.*)
- Protegin.**—Yellowish, soft, organic substance melting at about 40°. It is used as an emulsifying agent, giving water-in-oil emulsions, in the preparation of cosmetic creams. (*Goldschmidt, Essen; M. R. Chemical Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Protosil** (Silvol).—Brand of Argenti Proteinas Mite. (*Parke Davis, London.*)
- Psicaine**.—Acid tartrate of *d*- γ -cocaine used as a local anæsthetic. (*Merck, Darmstadt; Napp, London.*)
- Psylla**.—Brand of Psyllium. (*Battle Creek Food Co., Battle Creek; Coates and Cooper, London.*)
- Purgen**.—Tablets containing phenolphthalein. They are supplied in three strengths containing in each tablet respectively 0.05, 0.1 and 0.5 gramme of phenolphthalein. (*Kirby, London.*)
- Pyramidon**.—Brand of Amidopyrina. (*Bayer Products, London.*)
- Pyridium**.—Hydrochloride of phenylazo- $\alpha\alpha$ -diaminopyridine, an antiseptic used in the treatment of infections of the urinary tract. It is administered orally in doses of 0.2 gramme (3 grains) three times daily in the form of 0.1 gramme tablets. For local application to infected surfaces, it may be applied in aqueous solution (1 per cent.), or as an ointment (10 per cent.) or powder. (*Pyridium Corporation, New York; Menley and James, London.*)
- Pyrolactin**.—Sterile fat-free milk, either plain or prepared with various additions, for injection in treatment by non-specific protein therapy. (*Research Products, London.*)
- Quadroneal**.—Combination of phenazone, phenacetin, caffeine and lactyl-*p*-phenetidin in tablet form for administration as an analgesic. (*Asta, Brackwede; Pharmaceutical Products, London.*)
- Quadro-Nox**.—Combination of barbitone, 80 per cent., and Quadroneal, 20 per cent., in the form of tablets weighing 0.6 gramme. It is used as a soporific. (*Asta, Brackwede; Pharmaceutical Products, London.*)
- Quinine-Phytin**.—Combination of Phytin and quinine in tablet form. (*Ciba, London.*)
- Quinisal**.—Brand of Quininæ Disalicylosalicylas. (*Boehringer, Mannheim.*)
- Quinisan**.—Brand of Quininæ Disalicylosalicylas. (*Howards, Ilford.*)
- Quinoplasmoquine**.—Combination of 0.01 gramme of Plasmoquine and 0.3 gramme of quinine sulphate in tablet form. (*Bayer Products, London.*)
- Quinostab**.—A 10 per cent. suspension of quinine iodobismuthate in olive oil, for the treatment of syphilis. (*Boots, Nottingham.*)
- Quinoxyl**.—Iodoxyhydroxyquinolinesulphonic acid, 80 per cent., with sodium bicarbonate, 20 per cent. It occurs as a yellow powder soluble in water, and is administered as an antiseptic, particularly in the treatment of anæmic dysentery, in doses of 0.25 to 1 gramme (4 to 15 grains) three times a day. It may also be administered by rectal injection of 200 millilitres of a 2.5 per cent. solution. (*Burroughs Wellcome, London.*)
- Radiostol**.—Brand of Liquor Ergosterolis Irradiati. It is also available in the form of pellets each equivalent to 1 millilitre (15 minims) of the solution. (*British Drug Houses, London.*)
- Radiostoleum**.—Mixture of Radiostol solution with a concentrate of vitamin A. It is supplied as an oily solution containing 3000 units of vitamin D per gramme and having a vitamin A activity of 500 blue units, or in capsules. (*British Drug Houses, London.*)
- Renaglandin**.—Brand of Liquor Adrenalinæ Hydrochloridi. (*Oppenheimer, London.*)
- Resyl**.—Preparation containing glyceroguaiacolether administered orally or by intramuscular injection, as a substitute for guaiacol. (*Ciba, London.*)
- Rhodan-Calcium Diuretin**.—Combination of 7½ grains of Calcium-Diuretin and 1½ grains of potassium thiocyanate in tablet form. It is administered in the treatment of hypertonia and arteriosclerosis. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Rhodapurin.**—Trimethylxanthinethiocyanammonia in tablet form. It is administered in the treatment of arterial hypertension. (*Homburg, Frankfurt; Spicer, London.*)
- Riodine.**—Iodoglyceric ester of ricinoleic acid. It is administered in the form of capsules containing the equivalent of 0.2 gramme of iodine as a substitute for inorganic iodides. (*Astier, Paris; Wilcox Jozeau, London.*)
- Rivanol.**—2-Ethoxy-6 : 9-diaminoacridine lactate, a yellow, water-soluble dye. It is used as a general antiseptic in dilutions of 1 in 2000 to 1 in 500. Solutions of 1 in 5000 are employed as enemata in the treatment of amœbic dysentery. (*Bayer Products, London.*)
- Rubyl.**—Suspension of quinine bismuth iodide in oil, supplied in ampoules containing 0.3 gramme in 3 millilitres for intramuscular injection in the treatment of syphilis. (*May and Baker, London.*)
- Rutonal.**—Methylphenobarbitone. It is supplied in the form of 3 grain tablets for administration as a sedative and hypnotic, particularly in the treatment of epilepsy. (*May and Baker, London.*)
- Salen.**—Liquid mixture of the methyl- and ethyl-glycolic acid esters of salicylic acid. It is applied locally, diluted if necessary with a mixture of chloroform and olive oil, in the treatment of rheumatic affections and neuralgia. It is also supplied as an ointment (Salenal) containing 33 per cent. (*Ciba, London.*)
- Sal-Ethyl.**—Brand of Æthylis Salicylas. (*Parke Davis, London.*)
- Sal Ethyl Carbonate.**—Carbonic acid ester of ethyl salicylate administered in the form of 5 grain tablets as an analgesic and antipyretic. (*Parke Davis, London.*)
- Salipyrin.**—Brand of Phenazoni Salicylas. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Salit.**—Bornyl salicylate, an oily liquid insoluble in water, miscible with alcohol, ether, chloroform and fixed oils. It is applied externally, either diluted with oil or as an ointment, in the treatment of neuralgia and rheumatism. (*Heyden, Dresden; Braun, London.*)
- Salophen.**—Acetyl-p-amidosalol, white crystals, insoluble in water. It is administered in doses of 0.3 to 1 gramme (5 to 15 grains) in the treatment of neuralgia and rheumatic conditions. (*Bayer Products, London.*)
- Salvarsan.**—Brand of Arsphenamina. (*Bayer Products, London.*)
- Salyrgan.**—Complex compound of mercury and sodium salicylallylamino-o-acetate, containing about 40 per cent. of mercury. It is used as a diuretic in cardiac or renal œdema, being administered intramuscularly or intravenously as a 10 per cent. solution in doses of 0.5 to 2 millilitres (8 to 30 minims). (*Bayer Products, London.*)
- Sandoptal.**—isoButylallylbarbituric acid in tablet form. It is administered as a sedative and hypnotic in doses of 3 to 9 grains. (*Sandoz, London; Brooks and Warburton, London.*)
- Sanocrysin.**—Brand of Auri et Sodii Thiosulphas. (*Dansk Chemo-Therapeutisk Selskab, Copenhagen; Napp, London.*)
- Santyl.**—Salicylic ester of santalol. It is administered in capsules in place of oil of sandal wood. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Saridone.**—Combination of phenyldimethylisopropylpyrazolone, $1\frac{1}{2}$ grains, phenacetin, $2\frac{1}{2}$ grains, and caffeine, $\frac{1}{2}$ grain, in tablet form. It is administered as an analgesic in doses of 1 to 3 tablets. (*Hoffman-La Roche, London.*)
- Sauerin.**—Culture of *Bacillus Bulgaricus* supplied in liquid form for the preparation of curdled milk, or in capsules for internal administration. (*Allen and Hanburys, London.*)

Substances with Proprietary Trade-Names—Continued.

Saxin.—Brand of Saccharinum in tablet form. (*Burroughs Wellcome, London.*)

Scillaren.—Mixture of the glycosides of squill having an action on the heart similar to that of digitalis. It is administered orally in the form of tablets or solution, in doses of 0·0008 to 0·0016 gramme ($\frac{1}{2}$ to $\frac{1}{16}$ grain), and is also prepared for intravenous administration when immediate effects are required. (*Sandoz, London; Brooks and Warburton, London.*)

Scleroveine.—Sterile solution of sodium salicylate supplied in ampoules for the injection treatment of varicose veins. (*Bengué, London.*)

Scuriforme.—*n*-Butyl *p*-aminobenzoate, a white, crystalline powder, very slightly soluble in water. It is used in oily or glycerin-alcohol solution as a local anæsthetic. (*May and Baker, London.*)

Sedasprin.—Acetylbromosalicylic acid. It is administered in the form of tablets or cachets in doses of 0·3 to 0·6 gramme (5 to 10 grains) as a sedative. (*Martindale, London.*)

Sedin.—Combination of potassium bromide, 0·4 gramme (6½ grains), sodium bromide, 0·4 gramme (6½ grains), and ammonium bromide, 0·2 gramme (3 grains) with vegetable extractive, in tablet form. It is administered dissolved in hot water as a sedative bouillon. (*Hommel's Hæmatogen Co., London.*)

Sedobrol.—Tablets containing in each about 1·1 grammes (17 grains) of sodium bromide with vegetable extractives. It is administered dissolved in hot water as a sedative bouillon. (*Hoffman-La Roche, London.*)

Sedormid.—Allylisopropylacetylurea. It is administered in doses of 0·25 gramme (4 grains) or more as a sedative and hypnotic. (*Hoffman-La Roche, London.*)

Selarom.—Mixture of the calcium, magnesium and sodium salts of aliphatic acids used as a substitute for sodium chloride in salt-free dietary. (*Bayer Products, London.*)

Seroden.—Combination of iodine with serum proteins. It is administered in the form of capsules containing 1 grain of organically combined iodine as a substitute for inorganic iodides. (*Allen and Hanburys, London.*)

Sextate.—Brand of Methylcyclohexanylis Acetas. (*Howards, Ilford.*)

Sextol.—Brand of Methylcyclohexanolum. (*Howards, Ilford.*)

Sextone.—Brand of Cyclohexanonum. (*Howards, Ilford.*)

Sextone B.—Brand of Methylcyclohexanonum. (*Howards, Ilford.*)

Shadoform.—Prepared barium sulphate for the preparation of a barium meal. Shado-Cream is a prepared barium meal. (*British Drug Houses, London.*)

Silantox.—Colloidal silica. It is used as an intestinal absorbent and is also used externally as a compound dusting powder. (*Silica Gel, London; Savory and Moore, London.*)

Silver Salvarsan.—Brand of Arsphenamina Argentica. (*Bayer Products, London.*)

Sionin.—*d*-Sorbitol, used as a substitute for sugar for use by diabetics. (*Bayer Products, London.*)

Sistomensin.—Lipo-soluble ovarian hormone. It is administered in the treatment of menorrhagia and in affections of the menopause. (*Cila, London.*)

Soamin.—Brand of Sodii Aminarsonas. (*Burroughs Wellcome, London.*)

Soderseine.—Colloidal suspension of bismuth sesquioxide. It is administered in doses of $\frac{1}{2}$ to 2 fluid ounces in the treatment of pertussis. (*Pecoul, Paris; Wilcox Jozeau, London.*)

Sodium Amytal.—Sodium derivative of Amytal. It may be administered by intravenous injection as a 10 per cent. solution in doses of 0·25 to 1 gramme (4 to 15 grains). (*Eli Lilly, London.*)

Substances with Proprietary Trade-Names—Continued.

- Sodium Diarsenol.**—Sodium derivative of Diarsenol. (*Diarsenol Co., Buffalo.*)
- Sodium Salvarsan.**—Sodium derivative of Salvarsan. (*Bayer Products, London.*)
- Solactol.**—Brand of *Æthylis Lactas*. (*Byk-Guldemerke, Berlin.*)
- Solargentum.**—Brand of *Argenti Proteinæ Mite*. (*Squibb, New York.*)
- Solganal.**—Di-sodium salt of 4-sulphomethylamino-2-auromercaptobenzol-1-sulphonic acid. It is administered intravenously in the treatment of tuberculosis and leprosy, in doses of from 0.01 to 0.5 gramme ($\frac{1}{4}$ to $7\frac{1}{2}$ grains). It is also prepared for oral administration in infective arthritis. (*Schering, London.*)
- Solganal B.**—Aurothioglucose. It is administered intramuscularly in solution or in suspension in oil in doses of 0.01 to 0.5 gramme ($\frac{1}{4}$ to $7\frac{1}{2}$ grains). (*Schering, London.*)
- Solurol.**—Brand of *Acidum Thyminicum*. (*Allen and Hanburys, London.*)
- Solution S.T.37.**—Solution of hexyl-resorcinol for topical application as an antiseptic. (*Sharp and Dohme, London.*)
- Somnifaine.**—Solution of the diethylamine salts of diethyl- and allylisopropyl-barbituric acids. It is administered in drops or by intramuscular injection as a sedative and hypnotic. (*Hoffman-La Roche, London.*)
- Somnigen.**—Dialysed solution in sherry of the hydrobromides of the total alkaloids of opium, containing 0.75 per cent. w/v of morphine. It is administered in doses of 5 to 40 minims. (*Hewlett, London.*)
- Somnoform.**—Anæsthetic for use by inhalation in dentistry, containing ethyl chloride, methyl chloride and ethyl bromide. (*de Trey, Berlin.; Amalgamated Dental Co., London.*)
- Somnos.**—Elixir containing 5.5 per cent. of chloral glycerolate. It is administered in doses of 4 to 8 millilitres (1 to 2 fluid drachms) as a sedative and 15 to 30 millilitres ($\frac{1}{2}$ to 1 fluid ounce) as a hypnotic. (*Sharp and Dohme, London.*)
- Somnosal.**—Combination of α -bromisovalerianylurea (2 parts) and amidopyrine (1 part). It is administered in doses of $7\frac{1}{2}$ to 15 grains as a sedative and soporific. (*Napp, London.*)
- Soneryl.**—Butylethylbarbituric acid. It is supplied in tablet form or in solution in ampoules for administration as a sedative and hypnotic in doses of from 0.1 to 0.3 gramme ($\frac{1}{2}$ to $4\frac{1}{2}$ grains). (*May and Baker, London.*)
- Soneryl-Sodium.**—Sodium derivative of Soneryl. It is supplied in the form of capsules containing 0.15 gramme ($2\frac{1}{2}$ grains) and is administered as a pre-operative basal anæsthetic in doses of approximately one capsule per 36 pounds body weight. (*May and Baker, London.*)
- Soricin.**—Brand of *Sodii Ricinoleas*. (*Merrell, Cincinnati; Squire, London.*)
- Spasmalgin.**—Mixture of papaverine, a sulphonated derivative of atropine and a preparation of the total alkaloids of opium. It is administered orally in tablets or by subcutaneous or intramuscular injection of a solution for the relief of spasmic and other pains. (*Hoffman-La Roche, London.*)
- Spasmine.**—Brand of *Benzylis Succinas*. (*Bush, London.*)
- Spasmodin.**—Brand of *Benzylis Benzoas*. (*Bush, London.*)
- Spasticine.**—Combination of benzyl succinate, papaverine hydrochloride and atropine methylbromide in tablet form. It is administered as a sedative for plain muscle organs. (*Napp, London.*)
- Sphagnol.**—A tar product prepared from peat and used in the form of ointment and soap in the treatment of various skin affections. (*Peat Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Spirobismol.**—Oily solution of a preparation of lecithin and quinine iodobismuthate. It is administered by intramuscular injection in the treatment of syphilis. (*Homburg, Frankfurt; Spicer, London.*)
- Spirocid.**—Brand of Acetarsol. (*Bayer Products, London.*)
- Spiroline.**—Preparation containing in each fluid drachm 3 grains of diiodocaffeine hydriodide and the soluble constituents of $7\frac{1}{2}$ grains of coffee. It is administered in doses of 1 fluid drachm in the treatment of asthma. (*British Drug Houses, London.*)
- Spirosal.**—Monoglycol salicylate, $C_6H_4(OH) \cdot COO \cdot CH_2CH_2OH$. It is applied externally, diluted with alcohol or olive oil, or in an ointment, as an anti-rheumatic. (*Bayer Product, London.*)
- Splenoxid.**—Flavoured liquid extract of spleen. It is administered in the treatment of tuberculous lungs, bones and joints, and of polycythaemia. (*Oxo, London.*)
- Stabilarsan.**—Arsphenamine diglucoside in dextrose solution, supplied in ampoules for use in the treatment of syphilis. (*Boots, Nottingham.*)
- Stabismol.**—Solution of an oil-soluble bismuth compound in olive oil, each millilitre containing the equivalent of 0.08 gramme of metallic bismuth. It is supplied in 2.5 millilitre and 1.2 millilitre ampoules and 1 fluid ounce bottles, for intramuscular injection in the treatment of syphilis. (*Boots, Nottingham.*)
- Stannoxy.**—Preparations containing tin in various forms for use in the treatment of furunculosis and other staphylococcal infections. Tablets for oral administration contain 42.5 per cent. of metallic tin and 7.5 per cent. of tin oxide. The liquid and ointment contain stannous chloride. It is also supplied in 2 millilitre ampoules, containing the equivalent of 0.004 gramme of tin, for intramuscular injection. (*Robert et Carrière, Paris; Anglo-French Drug Co., London.*)
- Staphar.**—Mixed staphylococcus vaccine. (*Bayer Products, London.*)
- Stipolac.**—Brand of Iodophthaleinum. (*Burroughs Wellcome, London.*)
- Stovaine.**—Brand of Amylocainæ Hydrochloridum. (*May and Baker, London.*)
- Stovarsol.**—Brand of Acetarsol. (*May and Baker, London.*)
- Stovarsol-Sodium.**—Sodium salt of Stovarsol. It is supplied in ampoules containing 0.5 to 1.5 gramme for intramuscular or subcutaneous injection in the treatment of yaws and malaria. (*May and Baker, London.*)
- Strophanthone.**—Physiologically standardised, non-alcoholic preparation of the active principles of strophanthus. It is administered orally in doses of 0.12 to 0.6 millilitre (2 to 10 minims) and is also prepared for hypodermic or intravenous administration. (*Parke Davis, London.*)
- Styptarnin.**—Brand of Cotarninæ Chloridum. (*Allen and Hanburys, London.*)
- Stypticin.**—Brand of Cotarninæ Chloridum. (*Merck, Darmstadt; Napp, London.*)
- Styptol.**—Brand of Cotarninæ Phthalas in tablet form. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Styracol.**—Brand of Guaiacolis Cinnamas. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Sulfarsenol.**—Brand of Sulpharsphenamina. (*Laboratoire Biochimie Médicale, Paris; Modern Pharmacals, London.*)
- Sulfosin.**—Sterile 1 per cent. solution of sulphur in olive oil, supplied in ampoules containing 2, 5 or 10 millilitres for use in the treatment of syphilis, particularly neurosyphilis. It is administered in doses of 1 millilitre gradually increased to 10 millilitres until the temperature rises to 104°F. (*Leo, Copenhagen; Bencard, London.*)
- Sulphostab.**—Brand of Sulpharsphenamina. (*Boots, Nottingham.*)

Substances with Proprietary Trade-Names—Continued.

- S.U.M.36.**—Complex organic symmetrical urea administered by intramuscular injection in the treatment of gonococcal infections. (*British Drug Houses, London.*)
- S.U.P.36.**—Complex organic symmetrical urea administered by intramuscular injection in the early stages of influenza and other acute inflammatory conditions, in doses of 0.5 to 1 millilitre of a 1 per cent. solution. (*British Drug Houses, London.*)
- S.U.P.468.**—Complex organic symmetrical urea administered by intramuscular injection in the treatment of acute streptococcal infections and in erysipelas. (*British Drug Houses, London.*)
- Superol.**—Brand of Potassii Hydroxyquinolini Sulphas. (*Superol, Beverwijk.*)
- Suprachol.**—Sodium dehydrocholate supplied in solution for intravenous administration or in the form of tablets for oral administration in the treatment of hepatic disorders. (*Richier, London.*)
- Suprarenalin.**—Brand of Adrenalina. (*Armour, London.*)
- Suprarenin.**—Brand of Adrenalina. (*Bayer Products, London.*)
- Synthalin.**—Decamethylenediguanidine dihydrochloride. It is given by the mouth in doses of from 0.01 gramme ($\frac{1}{10}$ grain) as a substitute for insulin. (*Schering, London.*)
- Synthalin B.**—Dodecamethyldiguanidine hydrochloride. It is given by the mouth in doses of 0.005 gramme ($\frac{1}{20}$ grain) as a substitute for insulin. (*Schering, London.*)
- Takadiastase.**—Enzyme obtained from a species of *Eurotium oryzae*, cultivated on wheat bran. It has marked amylolytic properties and is used in the treatment of amylaceous dyspepsia in doses of 0.06 to 0.3 gramme (1 to 5 grains). (*Parke Davis, London.*)
- Tannalbin.**—Albumin tannate. It is administered in doses of 0.5 to 1 gramme ($7\frac{1}{2}$ to 15 grains) as an intestinal antiseptic. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Tannigen.**—Brand of Acetannin. (*Bayer Products, London.*)
- Tannoform.**—Brand of Methyleneeditannin. (*Merck, Darmstadt; Napp, London.*)
- Tegin.**—Organic wax-like substance melting at 57°. It is used as an emulsifying agent, giving oil-in-water emulsions in the preparation of cosmetic creams. (*Goldschmidt, Essen; M. R. Chemical Products, London.*)
- Tenebryl.**—Sodium salt of diiodomethanesulphonic acid, containing 68 per cent. of iodine. It is used for intravenous pyelography and for various X-ray explorations and is administered in doses of 15 grammes dissolved in 75 millilitres of distilled water. (*Guerbet, St. Ouen; Bengué, London.*)
- Terpichin.**—Oily solution containing oil of turpentine and quinine. It is administered by injection in the treatment of various skin affections. (*Oestreicher, Berlin; C. Zimmermann, London.*)
- Testamon.**—Desiccated testicular substance in tablet form. (*Organon Laboratories, London.*)
- Tetanol.**—Calcium levulinate. It is administered in the treatment of calcium deficiency in doses of 5 to 20 millilitres of a 13 per cent. solution given intravenously, or 2 millilitres of a 25 per cent. solution given intramuscularly. (*British Colloids, London.*)
- Tetraform.**—Brand of Carbonei Tetrachloridum. (*British Drug Houses, London.*)
- Tetrophan.**—Dihydronaphthacridinemesocarboxylic acid, a synthetic derivative of quinolinecarboxylic acid, in tablet form. It is administered in doses of 0.1 gramme ($1\frac{1}{2}$ grains) in the treatment of disseminated sclerosis and other diseases of the central nervous system. (*Riedel-de Haen, Berlin, Old Strand Chemical and Drug Co., London.*)

Substances with Proprietary Trade-Names—Continued.

- Thallium-Depilatorium.**—Preparation of thallium administered internally for the production of epilation in the treatment of ringworm. (*Schering, London.*)
- Theacylon.**—Acetylsalicyloyltheobromine. It is administered as a diuretic in the treatment of œdema of cardiac origin. (*Merck, Darmstadt; Napp, London.*)
- Theelin.**—Brand of ketohydroxyœstrin (see Oestrinum). It is supplied for hypodermic administration as a solution in ampoules containing 50 Doisy rat units per millilitre, and is administered in doses of 1 to 2 millilitres. It is also supplied in the form of pessaries containing 50 rat units. (*Parke Davis, London.*)
- Theelol.**—Brand of trihydroxyœstrin (see Oestrinum). It is supplied in capsules each representing 50 Doisy rat units. (*Parke Davis, London.*)
- Thelestrin.**—Solution of ketohydroxyœstrin (see Oestrinum) for hypodermic injection, each millilitre containing 25 Doisy rat units. (*Carrick, Newark, N.J.; Brooks and Warburton, London.*)
- Theocin.**—Brand of Theophyllina. (*Bayer Products, London.*)
- Theogardenal.**—Combination of theobromine, 5 grains, and Gardenal, $\frac{1}{2}$ grain, in tablet form. (*May and Baker, London.*)
- Theominal.**—Combination of 0.03 gramme ($\frac{1}{2}$ grain) of Luminal and 0.3 gramme (5 grains) of theobromine in tablet form. (*Bayer Products, London.*)
- Thigenol.**—Solution of sodium sulpholeate applied externally in the treatment of acne and herpes. (*Hoffmann-La Roche, London.*)
- Thilocologne.**—Brand of Æthylis Chloridum containing 0.5 per cent. of eau de Cologne. (*Thilo, Mainz; Coates and Cooper, London.*)
- Thio-Bismol.**—Sodium bismuth thioglycollate. It is administered in doses of 0.15 to 0.2 gramme by intramuscular injection of an aqueous solution in the treatment of syphilis. (*Parke Davis, London.*)
- Thiocol.**—Brand of Potassii Guaiacolsulphonas. (*Hoffman-La Roche, London.*)
- Thiol.**—Preparation used for the same purposes as Ichthammol. (*Riedel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Thiostab.**—Sterile 10 per cent. solution of sodium thiosulphate for injection in the treatment of intoxication arising from the administration of arsenic, bismuth, or mercury preparations. (*Boots, Nottingham.*)
- Thorotrast.**—Colloidal solution containing 25 per cent. of thorium dioxide stabilised by carbohydrates. It is used as a contrast medium for the X-ray diagnosis of sinuses, etc., for pyelography, cystography and similar purposes. (*Heyden, Dresden; Braun, London.*)
- Thyracoids.**—Biologically standardised iodothyroglobulin in tablet form. It is administered for the same purposes as Thyroideum. (*Reed and Carrick, Jersey City; Coates and Cooper, London.*)
- Thyraden.**—Thyroid extract in tablet form, each tablet containing the equivalent of 0.3 gramme of fresh gland. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Thyranon.**—Brand of Thyroideum, standardised biologically and also standardised chemically to contain 0.2 per cent. of organic iodine. (*Organon Laboratories, London.*)
- Thyrocol.**—Preparation used for the same purposes as Thyroideum. (*Oppenheimer, London.*)
- Thyroidectin.**—Powder prepared from the blood of thyroidectomised animals, administered in doses of 5 grains in the treatment of hyperthyroidism. (*Parke Davis, London.*)

Substances with Proprietary Trade-Names—Continued.

- Thyroprotein.**—Prepared extract of thyroid standardised to contain 0.33 per cent. of organically combined iodine. It is administered in doses of $\frac{1}{10}$ to $\frac{1}{5}$ grain. (*Parke Davis, London.*)
- Tin-Ox.**—Combination of tin and tin oxide in tablet form, administered in the treatment of furunculosis and staphylococcal infections. (*John Bell, Hills, and Lucas, London.*)
- Tiodine.**—Brand of Thiosinaminæ Æthylis Iodidum. (*Gognet, Paris; Roberts, London.*)
- Tolamine.**—Brand of Chloramina. (*Burroughs Wellcome, London.*)
- Tolysin.**—Brand of Neocinchophenum. (*Calco, Bound Brook, N.J.; Martindale, London.*)
- Tonocholin.**—Acetylcholinæ Hydrochloridum in aqueous solution containing 0.05 gramme per millilitre. (*Richter, London.*)
- Torost.**—Combination of Ostelin with an extract of yeast containing the vitamin B complex in tablet form. Each tablet contains 500 units of vitamin D and the equivalent of 10 grains of fresh yeast. (*Glaxo Laboratories, London.*)
- Transpulmin.**—Oily solution of quinine and camphor administered by intramuscular injection in the treatment of affections of the lower air-passages. (*Homburg, Frankfurt; Spicer, London.*)
- Tréparsol.**—Formyl-*m*-amino-*p*-oxyphenylarsonic acid in tablet form. It is administered orally in the treatment of syphilis. (*Lecoq et Ferrand, Paris; Bengué, London.*)
- Trépol.**—Oily suspension of bismuth oxytartrate for administration by intramuscular injection in the treatment of syphilis and yaws. (*Chenel et Douilhet, Paris; Anglo-French Drug Co., London.*)
- Tricalcine.**—Mixture of tribasic phosphates, carbonates and other salts of calcium and magnesium. It is administered in the treatment of mineral deficiency. (*Scientia, Paris; Wilcox Jozeau, London.*)
- Triferrin.**—Organic preparation containing about 15 per cent. of iron and 2 to 2.5 per cent. of phosphorus in tablet form. (*Knoll, Ludwigshafen; Pharmaceutical Products, London.*)
- Trigemin.**—Combination of amidopyrine and butylchloral hydrate. It is supplied in various forms for administration in doses of 0.25 to 0.5 gramme ($3\frac{1}{4}$ to $7\frac{1}{2}$ grains) as an analgesic. (*Bayer Products, London.*)
- Trikresol.**—Mixture of *o*-, *m*- and *p*-cresol. (*Schering, London.*)
- Trilactine.**—Preparation containing lactic acid-forming bacilli. (*Martindale, London.*)
- Trional.**—Brand of Methysulphonal. (*Bayer Products, London.*)
- Triphal.**—Sodium salt of aurothiobenzimidazocarboxylic acid. It is given in doses of 0.025 to 0.2 gramme ($\frac{1}{2}$ to 3 grains) in the treatment of tuberculosis. (*Bayer Products, London.*)
- Trivalin.**—Solution containing in 1 millilitre 0.0037 gramme ($\frac{1}{4}$ grain) of caffeine valerianate, 0.0054 gramme ($\frac{1}{2}$ grain) of cocaine valerianate and 0.0019 gramme ($\frac{1}{30}$ grain) of morphine valerianate. It is administered either orally or by injection in doses of 0.5 to 1 millilitre (8 to 15 minims) for the relief of pain. It is also available in the form of capsules. (*Saccharin Corporation, London.*)
- Tryparsamide.**—Registered name for Tryparsonum. (*Rockefeller Foundation, New York.*)
- Tutocaine.**—Hydrochloride of *p*-aminobenzoyldimethylaminomethylbutanol. It is used in 0.2 to 2 per cent. aqueous solution as a local anæsthetic. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Tylcalsin.**—Brand of Calcii Acetylsalicylas. (*Martindale, London.*)
- Tyllithin.**—Brand of Lithii Acetylsalicylas. (*Martindale, London.*)
- Umbrathor.**—Unstabilised colloidal solution of thorium dioxide for the X-ray visualisation of mucous membrane. (*Heyden, Dresden; Braun, London.*)
- Umbrenal.**—25 per cent. solution of lithium iodide for use in pyelography. (*Schering, London.*)
- Uden.**—Biologically standardised preparation of ketohydroxyoestrin (see Oestrium), administered orally or by intramuscular injection. (*Bayer Products, London.*)
- Urea Stibamine.**—Organic compound of antimony used in the treatment of kala-azar. (*Brahmachari Institute, Calcutta; Martindale, London.*)
- Urodonal.**—Granular effervescent preparation of hexamine, administered in the treatment of rheumatism. (*Chatelain, Paris; Spencer, London.*)
- Uroselectan.**—Sodium salt of 2-hydroxy-5-iodopyridine-N-acetic acid containing 47 per cent. of iodine. It is administered by intravenous injection of 100 millilitres of a 30 per cent. w/v solution in sterilised re-distilled water for the X-ray visualisation of the kidneys and urinary tract. (*Schering, London.*)
- Uroselectan-B.**—Di-sodium salt of 3 : 5-diiodo-4-pyridoxyl-N-methyl-2 : 6-dicarboxylic acid, containing 51 per cent. of iodine. It is administered by intravenous injection for the X-ray visualisation of the kidneys and urinary tract and is supplied in ampoules containing 20 millilitres of a solution of 15 grammes of the compound in 10 per cent. invert sugar solution. (*Schering, London.*)
- Urotropine.**—Brand of Hexamina. (*Schering, London*)
- Vagotonine.**—Pancreatic hormone supplied in ampoules containing 0·02 gramme for subcutaneous injection in the treatment of arterial hypertension and paroxysmal tachycardia. (*Byla, Paris; Anglo-French Drug Co., London.*)
- Validol.**—Mixture of menthol and menthyl valerianate. (*Zimmer, Mannheim; Pharmaceutical Products, London.*)
- Valisan.**—Borneol ester of bromoisovalerianic acid. It is supplied in the form of perles for administration as a sedative and soporific in doses of 7½ grains. (*Schering, London.*)
- Varixol.**—Sterile preparation of quinine and urethane used for the same purposes as Injectio Quininae et Urethani. (*Evans Sons Lescher and Webb, Liverpool.*)
- Vasano.**—Mixture of the camphoric acid salts of the alkaloids of mandragora roots (*l*-scopolamine and *l*-hyoscyamine), administered in the prophylactic and curative treatment of all forms of travel sickness. (*Schering, London.*)
- Veganin.**—Combination of acetylsalicylic acid, 0·25 gramme, phenacetin, 0·25 gramme, and codeine phosphate, 0·01 gramme, in tablet form. It is used as an analgesic and sedative. (*Warner, London.*)
- Ventræmon.**—Brand of Ventriculus Desiccatus in powder or tablet form. (*Organon Laboratories, London.*)
- Ventriculin.**—Brand of Ventriculus Desiccatus. (*Parke Davis, London.*)
- Veramon.**—Mixture of barbitone in combination with amidopyrine, with excess of amidopyrine. It is administered in doses of 0·4 gramme (6 grains) for the relief of pain. (*Schering, London.*)
- Veratrone.**—Physiologically tested preparation of the active principles of *Veratrum viride*. It is administered hypodermically in doses of 0·5 millilitre (8 minims). It may also be given orally in doses of 1 to 2 millilitres (15 to 30 minims). (*Parke Davis, London.*)
- Veronal.**—Brand of Barbitonum. (*Bayer Products, London.*)
- Veronal Sodium.**—Brand of Barbitonum Solubile. (*Bayer Products, London.*)

Substances with Proprietary Trade-Names—Continued.

- Veropyron.**—Combination of barbitone, 0.15 gramme, and amidopyrine, 0.35 gramme, in tablet form. (*Richter, London.*)
- Vesalvine.**—Brand of Hexamina. (*Martindale, London.*)
- Vesalvine B.**—Hexamine benzoate. It is administered in the treatment of cystitis and in bacterial infections of the urinary tract in doses of 0.3 to 1 gramme (5 to 15 grains). (*Martindale, London.*)
- Vesalvine S.**—Hexamine salicylate. It is administered in the treatment of cystitis and in bacterial infections of the urinary tract in doses of 0.3 to 1 gramme (5 to 15 grains). (*Martindale, London.*)
- Vigantol.**—Solution similar to *Liquor Ergosterolis Irradiati*. (*Bayer Products, London.*)
- Vioform.**—Iodochlorhydroxyquinoline. It is used as an almost odourless substitute for iodoform. (*Ciba, London.*)
- Viozin.**—Ointment containing zinc oxide with Ostelin, equivalent to 5000 international units of vitamin D per gramme, in a lanolin and paraffin base. It is used for the local treatment of varicose ulcers, fistulæ, indolent ulcers and similar conditions. (*Glaxo Laboratories, London.*)
- Vuzin.**—Brand of Octylhydrocupreïnæ Dihydrochloridum. (*Zimmer, Mannheim; Howards, Ilford.*)
- Westron.**—Brand of Tetrachlorethanum. (*Imperial Chemical Industries, London.*)
- Westrosol.**—Brand of Trichlorethylenum. (*Imperial Chemical Industries, London.*)
- Xeroform.**—Brand of Bismuthi Tribromphenas. (*Heyden, Dresden; Braun, London.*)
- Yatren.**—Iodohydroxyquinolinesulphonic acid mixed with sodium bicarbonate. It occurs as a yellow powder soluble in water. It is administered as an antiseptic, particularly in the treatment of amebic dysentery, in doses of 1 gramme (15 grains) three times a day. It may also be administered by rectal injection of 200 millilitres of a 2 per cent. solution. (*Bayer Products, London.*)
- Yatren-Casein.**—Preparation of Yatren for non-specific therapy. It is administered by intramuscular injection and is supplied in two strengths; the weak solution contains in one millilitre 0.025 gramme of Yatren and 0.025 gramme of casein and the strong solution contains the same proportion of Yatren with 0.05 gramme of casein. (*Bayer Products, London.*)
- Yohydrol.**—Brand of Yohimbina Hydrochloridum. (*Rudel-de Haen, Berlin; Old Strand Chemical and Drug Co., London.*)
- Zoin.**—Water-soluble salt of an aminophosphorus compound occurring in casein. It is administered orally in solution or in the form of tablets in the treatment of neurasthenia and debility. (*Ciba, London.*)
- Zymine.**—Extract of pancreas containing various digestive enzymes. (*Fairchild, Bros. and Foster, New York; Burroughs Wellcome, London.*)

INDEX

INDEX

TO THE

BRITISH PHARMACEUTICAL CODEX,

Where more than one reference is given, that of chief importance will be found in heavier type.
